1.9.1.6 Ships applying for the ASMW notation are to comply with the provisions of 1.9.7 of this Section.

1.9.2 Application

1.9.2.1 Unless otherwise stated, this Section applies to ships of 24 m and over in length, the types of which are covered by 1.9.4 and 1.9.6 of this Section.
1.9.2.2 For ships of less than 24 m in length, reference may be made to 1.9.2.1 of this Section.
1.9.2.3 For other ship types not covered by 1.9.4 and 1.9.6 of this Section, the criteria acceptable to CCS may be used.

1.9.3 Plans and documents

1.9.3.1 The following plans and documents are to be submitted for approval or confirmation:
(1) Stability calculations for loading conditions or loading manual;
(2) Curves or table of allowable height of center of gravity or allowable initial metacentric height;
(3) Coordinates of opening of flooding angles and curves or table of flooding angles;
(4) Stability information for carriage of grain (capacity of fully and partially filled compartments, curves or table of assumed volumetric heeling moment, curves or table of maximum permissible heeling moment) and stability calculations for loading conditions or loading manual (if applicable);
(5) Operational guidance for ships in high sea conditions (may be included in the loading manual) (if applicable).
1.9.3.2 The following plans and documents are to be submitted for information:
(1) General arrangement;
(2) Lines and offsets;
(3) Hydrostatic curves or table;
(4) Stability cross curves or table;
(5) Capacity curves or table;
(6) Arrangement of bilge keels;
(7) Plan of subdivision draught and load line marks;
(8) Auxiliary calculations for windage area and moment of area, crowding of all passengers towards one side, icing, etc.;
(9) Cross-sectional area (if applicable);
(10) Approved inclining test report or light ship survey report;
(11) Assessment calculations of operational guidance for ships in high sea conditions (if applicable).
1.9.3.3 The above information may be reduced as appropriate for ships of which the intact stability has been approved, except for those of which service has been changed.

1.9.4 Requirements for intact stability

1.9.4.1 The intact stability of ships is to comply with the relevant requirements of IMO resolution MSC.267(85) – International Code on Intact Stability, 2008 (2008 IS Code) and its amendments. For ships with $B/D \geq 2.5$, the requirements of 2.2.3 of Part A of the Code may be substituted by the following criteria:
(1) The heeling angle θ_{max} corresponding to the maximum righting lever GZ is not to be less than 15°.

(2) The area under the curve of righting levers (GZ curve) is not be less than 0.07 m·rad up to an angle of 15° when the maximum righting lever (GZ) occurs at 15º and 0.055 m·rad up to an angle of 30º when the maximum righting lever (GZ) occurs at 30º or above. Where the maximum righting lever (GZ) occurs at angles of between 15º and 30º, the corresponding area under the righting lever curve is to be:

$$0.055+0.001\ (30^\circ - \theta_{max}) \qquad \text{m·rad}$$

1.9.4.2 The intact stability of oil tankers of 5,000 deadweight ton and above is also to comply with the relevant requirements of Regulation 27 of MARPOL Annex I.

1.9.4.3 The intact stability of open-top container ships is to comply with the relevant requirements of MSC/Circ.608/Rev. 1 – Interim Guidelines for Open-Top Container Ships.

1.9.4.4 The intact stability of polar ships having class notation PC and ships intended for navigation in ice and having class notation B1* or B1 are also to comply with the relevant requirements of resolution MSC.385(94) – International Code for Ships Operating in Polar Waters (Polar Code).

1.9.5 Stability of semi-submersible vessels in semi-submerged operation mode

1.9.5.1 Semi-submersible vessels are to operate in semi-submerged mode in the wind and wave conditions not more severe than those specified in 1.9.5.4 below. Such external environmental conditions are to be noted in stability calculations, operating manual and relevant certificates.

1.9.5.2 The stability in semi-submerged mode is to be checked to 10% of fuels, consumables and stores for operational loading conditions of 1.9.5.3 to 1.9.5.6.

1.9.5.3 Immediately before submerging with full deck cargo load, the initial metacentric height as corrected for free surface is not to be less than 1.0 m.

1.9.5.4 During the emerging and submerging of lifting cargo deck with full deck cargo load, the stability is to meet one of the following criteria:

(1) At the normal calm sea area with wind force not exceeding Beaufort scale 3, the initial metacentric height as corrected for free surface is not to be less than 0.05 m, or not less than 0.1 m with wind force not exceeding Beaufort scale 5;

(2) At the sea area with wind force not exceeding Beaufort scale 6 and significant wave height less than 0.5 m or with wind force not exceeding Beaufort scale 4 and significant wave height less than 1 m, the initial metacentric height as corrected for free surface is not to be less than 0.15 m.

1.9.5.5 At the maximum submerged depth, the initial metacentric height as corrected for free surface is not to be less than 0.5 m.

1.9.5.6 Throughout the emerging and submerging without deck cargo load, the initial metacentric height as corrected for free surface is not to be less than 0.15 m.

1.9.5.7 Whenever free liquid surface exists in a tank, the maximum effect of free surface in the tank is to be taken into account.

1.9.5.8 For submerging with large items, ships or offshore installations being carried, their effects on stability may be considered according to their actual positions and floating condition.

1.9.5.9 An appropriate operating manual for operations in semi-submerged mode is to be prepared to specify submerging procedure and operational steps for ensuring compliance with the requirements of 1.9.5.3 to 1.9.5.6. This manual is to be submitted to CCS for information.

1.9.6 Second generation intact stability criteria

1.9.6.1 Ships are to comply with the relevant requirements of CCS Guidelines on Assessment of Ship Second Generation Intact Stability Criteria.

1.9.6.2 Second generation intact stability calculations are to be submitted for information.

1.9.7 Operational guidance for ships in high sea conditions

1.9.7.1 Hydrodynamic-based methods are to be used to analyze the performance and characteristics of the ship, assess the sailing conditions that may affect safety, and prepare operational guidance for ships in potential high sea conditions for the master's reference.

1.9.7.2 Due to the influences of environmental conditions, the ship's own state, human factors and other factors, operating the ship according to the ship's operational guidance in high sea conditions cannot ensure that the ship can completely avoid loss of stability, excessive movement and capsizing accidents when sailing in adverse sea conditions, nor can the master be released from the responsibility of the ship's navigation safety.

1.9.7.3 The likelihood of different modes of navigation safety failures under the combined or separate action of wind and waves is to be assessed, and operational guidance for ships in high sea conditions is to be developed accordingly. Modes of navigation safety failures that are to be assessed include:

(1) excessive roll or excessive acceleration caused by parametric rolling;

(2) excessive roll or excessive acceleration caused by synchronous rolling motion during navigation;
(3) loss of stability caused by pure loss of stability;
(4) excessive roll/capsizing or insufficient stability caused by the combined action of wind and waves in the dead ship condition.
1.9.7.4 Navigation safety assessments are to be carried out for typical loading conditions in sailing conditions as a minimum and operational guidance for ships in high sea conditions is to be developed.
1.9.7.5 The level 2 criteria for parametric rolling in IMO MSC.1/Circ.1627 is to be used to calculate the amplitude of parametric rolling and the resultant lateral acceleration at the bridge when the ship is sailing at typical speed in head waves and following waves. Operational guidance for ships in high sea conditions is to include sailing and sea conditions where the calculated roll amplitude is greater than 25^{o} or lateral acceleration is greater than 4.64 m/s^2.
1.9.7.6 The level 2 criteria for pure loss of stability in IMO MSC.1/Circ.1627 is to be used to calculate the vulnerability index of ship's pure loss of stability. Operational guidance for ships in high sea conditions is to include sea conditions with a calculated vulnerability index of 1.0.
1.9.7.7 The potential flow theory is to be used to calculate the amplitude of parametric rolling and the resultant lateral acceleration at the bridge when the ship is sailing at typical speed in typical waves. Operational guidance for ships in high sea conditions is to include sailing and sea conditions where the calculated roll amplitude is greater than 25^{o} or lateral acceleration is greater than 4.64 m/s^2.
1.9.7.8 The meteorological criteria of the International Code for Intact Stability, 2008, adopted by IMO resolution MSC.267(85), is to be used to calculate the steady wind speed value (beam wind) that meets the requirements of the meteorological criteria, assuming that the ship is in a dead ship condition and that the roll angle caused by wave action is 25^{o}. Operational guidance for ships in high sea conditions is to include the steady wind speed value (beam wind).
1.9.7.9 The potential flow theory is to be used to calculate the amplitude of parametric rolling and the resultant lateral acceleration at the bridge when the ship is in the dead ship conditions in typical waves. Operational guidance for ships in high sea conditions is to include sailing and sea conditions where the calculated roll amplitude is greater than 25^{o} or lateral acceleration is greater than 4.64 m/s^2.
1.9.7.10 Other numerical simulations or model tests may be used as alternatives to navigation safety assessment subject to CCS agreement.
1.9.7.11 Operational guidance for ships in high sea conditions is to be provided in a loading manual or onboard computer-based system in a simple and clear form.

Section 10 DAMAGE STABILITY

1.10.1 General requirements

1.10.1.1 Compliance with the applicable requirements for damage stability is a condition for classification of ships.
1.10.1.2 The damage stability of ships is to comply with the requirements of this Section, or it is to be demonstrated that their damage stability is in compliance with the requirements of the flag State Administration.

1.10.2 Plans and documents

1.10.2.1 The following plans and documents are to be submitted for approval or confirmation:
(1) Calculations of damage stability;
(2) Damage control plan and damage control booklet (for passenger ships and dry cargo ships);
(3) Curves or table of allowable height of center of gravity or allowable initial metacentric height for damage stability (if applicable);
(4) Arrangement of cross-flooding fittings and calculations of cross-flooding duration (if applicable).
1.10.2.2 The following plans and documents are to be submitted for information:
(1) General arrangement of doors and windows;
(2) General arrangement of scuttles, ventilators and air pipes;
(3) Plans and documents stated in 1.9.3 of this Chapter.

1.10.3 Requirements for damage stability

1.10.3.1 The damage stability of ships is to comply with the relevant requirements of applicable regulations as shown in Table 1.10.3.1.
1.10.3.2 The stability of ships carrying timber deck cargo is to comply with the relevant requirements of IACS UI SC 161.

List of Applicable Regulations for Damage Stability **Table 1.10.3.1**

Ship type	Applicable regulation
Passenger ship, type B freeboard dry cargo ship and combination carrier*, type B-60 and type B-100 freeboard cargo ships intended for carriage of deck cargo	Part B-1, Chapter II-1 of International Convention for the Safety of Life at Sea (SOLAS)
Bulk carrier (additional requirements)	Reg. XII/4 of International Convention for the Safety of Life at Sea (SOLAS)
Type B-60, type B-100 and type A freeboard ships	Reg. 27 of the International Convention on Load Lines, 1966 (ICLL), as revised by Protocol of 1988
Chemical tanker	International Code for the Construction and Equipment of Ships Carrying Dangerous Chemicals in Bulk (IBC Code)
Liquefied gas carrier	International Code for the Construction and Equipment of Ships Carrying Liquefied Gases in Bulk (IGC Code)
Oil tanker (including combination carrier*)	Reg. 28 of Annex I of International Convention for the Prevention of Pollution from Ships, 1973, as modified by the 1978 Protocols (MARPOL)
Special purpose ship	Code Of Safety For Special Purpose Ships (2008 SPS Code)
Offshore supply vessel of not more than 100 m in length	Guidelines for the Design and Construction of Offshore Supply Vessels, 2006 (2006 OSV Guidelines)
Nuclear ship	Code of Safety for Nuclear Merchant Ships
Ship carrying INF and radioactive wastes	International Code for the Safe Carriage of Packaged Irradiated Nuclear Fuel, Plutonium and High-level Radioactive Wastes on Board Ships (INF Code)
Open-top container ship	MSC/Circ.608/Rev.1
Polar ship (notation PC) Ship intended for navigation in ice (class notation B1* or B1)	International Code for Ships Operating in Polar Waters (Polar Code)
Offshore support vessels transporting and handling hazardous and noxious liquid substances in bulk	Code for the Transport and Handling of Hazardous and Noxious Liquid Substances in Bulk on Offshore Support Vessels (OSV Chemical Code)
Ships using gases or other low-flashpoint fuels	International Code of Safety for Ships using Gases or other Low-flashpoint Fuels (IGF Code)

* Note: Combination carrier is a cargo ship designed to carry both oil and solid cargoes in bulk (see definition of SOLAS Reg. II-2/3.14).

Section 11 LOAD LINE MARKS AND MARKING

1.11.1 Application

1.11.1.1 The requirements of this Section apply to ships engaged on international voyages.

1.11.2 Load line marks

1.11.2.1 The load line mark for ships not carrying timber deck cargoes is shown in Figure 1.11.2.1.

1.11.2.2 The load line mark for ships carrying timber deck cargoes is shown in Figure 1.11.2.2.

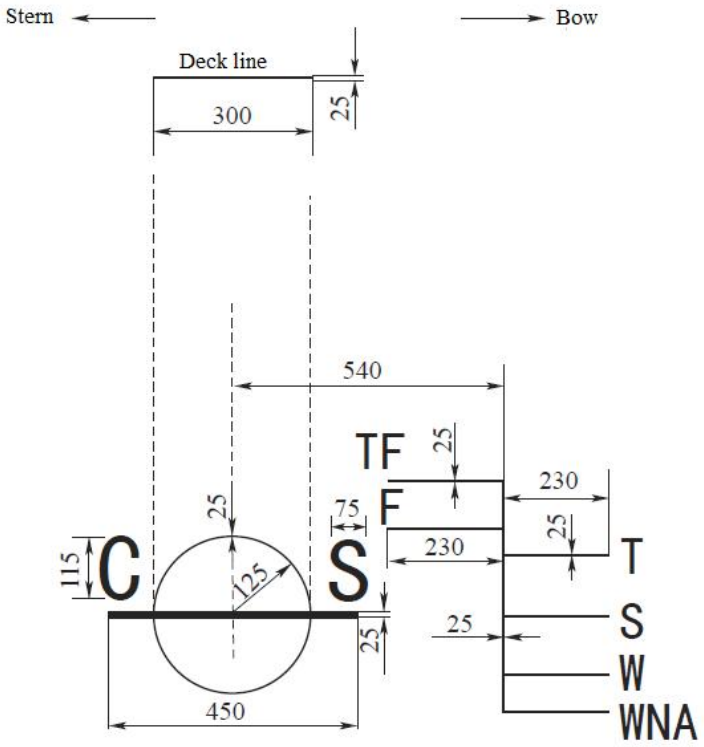

Figure 1.11.2.1 Freeboard Mark for Ships not Carrying Timber Deck Cargoes (in mm)

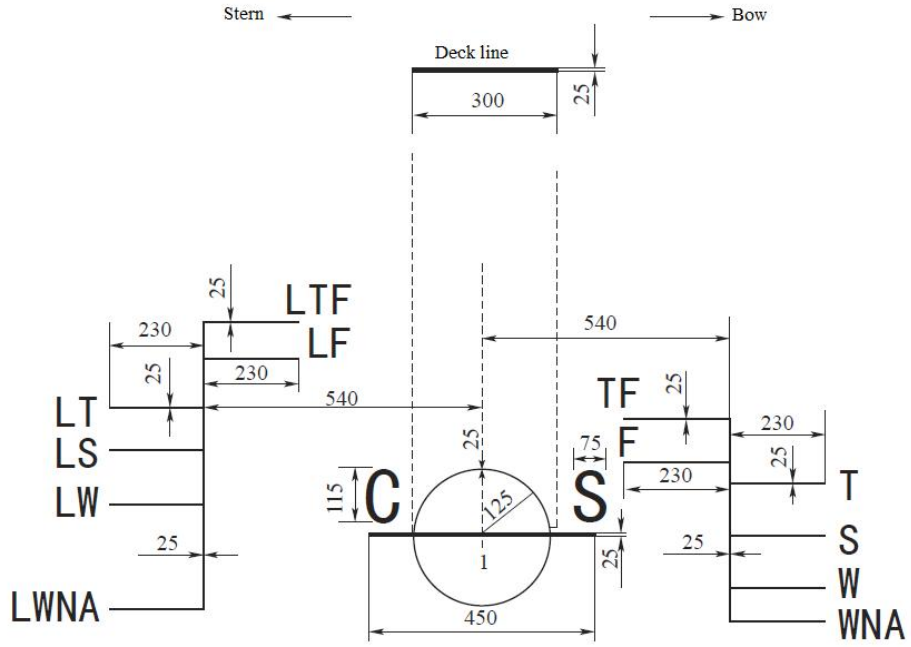

Figure 1.11.2.2 Freeboard Mark for Ships Carrying Timber Deck Cargoes (in mm)

1.11.2.3 Where a ship is assigned a greater than minimum freeboard so that the load line is marked at a position corresponding to, or lower than, the lowest seasonal load line assigned at minimum freeboard as specified in Annex B to the Protocol of 1988 Relating to the International Convention on Load Lines, 1966, only the Fresh Water Load Line need be marked. In such a case, the load line mark is as shown in Figure 1.11.2.3.

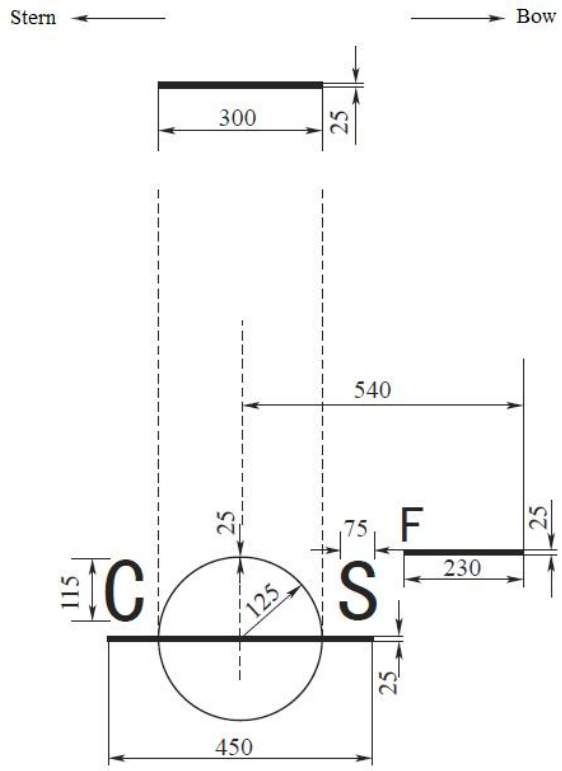

Figure 1.11.2.3 Fresh Water Load Line Only (in mm)

1.11.2.4 The subdivision load line mark for passenger ships is shown in Figure 1.11.2.4.

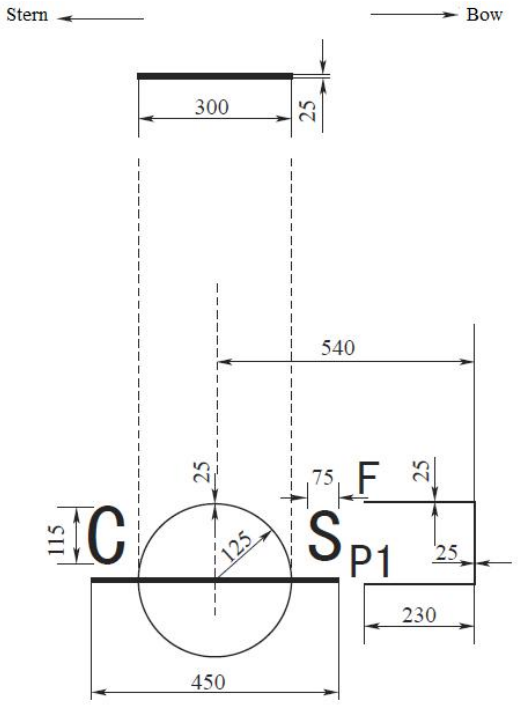

Figure 1.11.2.4 Subdivision Load Line Mark for Passenger Ships (in mm)

The symbols in Figures 1.11.2.1 to 1.11.2.4 are defined as follows:

C, S — China Classification Society;
F — Summer Fresh Water Load Line;
S — Summer Load Line;
WNA — Winter North Atlantic Load Line;
LF — Summer Fresh Water Timber Load
TF — Tropical Fresh Water Load Line;
T — Tropical Load Line;
W — Winter Load Line;
LTF — Tropical Fresh Water Timber Load Line;
LT — Tropical Timber Load Line;

Line;
LS — Summer Timber Load Line;
LW — Winter Timber Load Line;
LWNA — Winter North Atlantic Timber Load Line;
P1 — Passenger Ship Subdivision Load Line.

1.11.3 Marking

1.11.3.1 The Load line mark is to consist of a ring 300 mm in outside diameter and 25 mm wide which is intersected by a horizontal line 450 mm in length and 25 mm in breadth, the upper edge of which passes through the center of the ring. The center of the ring is to be placed on each side of the ship at the middle of the length as defined in the Annex B to the Protocol of 1988 Relating to the International Convention on Load Lines, 1966, and at a distance equal to the assigned summer freeboard measured vertically below the upper edge of the deck line. The ring, lines and letters are to be painted in white or yellow on a dark ground or in black on a light ground. They are to be permanently marked on both sides of the ship and clearly visible.

Section 12 STRUCTURAL ARRANGEMENT

1.12.1 General requirements

1.12.1.1 This Section specifies the requirements for the structural arrangement of hull structures of ships engaged in unrestricted service.

1.12.1.2 Unless stated otherwise, this Section applies to mechanically self-propelled ships engaged on international voyages.

1.12.2 Arrangement of watertight bulkheads

1.12.2.1 All ships are to be fitted with at least the following watertight bulkheads:

(1) one collision bulkhead;

(2) one after peak bulkhead;

(3) one bulkhead at both ends of the machinery space;

(4) the number of watertight bulkheads and their distribution along the ship's length for both passenger and cargo ships are to comply with the requirements for subdivision and stability contained in Sections 9 and 10 of this Chapter, in addition to the requirements of (1) to (3) above;

(5) the number of watertight bulkheads and their distribution along the ship's length for oil tankers of 600 deadweight tons and above are to comply with the requirements of Chapters 3 and 4 of MARPOL Annex I, in addition to the requirements of (1) to (3) above.

1.12.3 Arrangement of collision bulkhead

1.12.3.1 A collision bulkhead is to be fitted which is to be watertight up to the bulkhead deck of passenger ships and the freeboard deck of cargo ships. This bulkhead is to be located at a distance from the forward perpendicular (the perpendicular at the intersection of the load waterline L_L with the fore side of the stem) of not less than 0.05 L_L or 10m, whichever is the less, and, except as may be permitted by the Administration, not more than 0.08 L_L or 0.05 L_L + 3 m, whichever is the greater.

1.12.3.2 Where any part of the ship below the waterline extends forward of the forward perpendicular referred to in 1.12.3.1 of this Section, e.g., a bulbous bow, the distances specified in 1.12.3.1 of this Section are to be measured from a point either:

(1) at the mid-length of such extension;

(2) at a distance 0.015 L_L forward of the forward perpendicular; or

(3) at a distance 3m forward of the forward perpendicular,

whichever gives the smallest measurement.

1.12.3.3 The collision bulkhead may have steps or recesses, provided that they are within the limits specified in 1.12.3.1 and 1.12.3.2 of this Section.

1.12.3.4 Where a long forward superstructure is fitted, the collision bulkhead is to be extended weathertight to the deck next above the bulkhead deck of passenger ships and the freeboard deck of cargo ships. The extension need not be fitted directly above the bulkhead below provided it is located within the limits prescribed in 1.12.3.1 and 1.12.3.2 of this Section with the exception permitted by 1.12.3.5 of this Section and that the part of the deck which forms the step is made effectively weathertight.

1.12.3.5 Where bow doors are fitted and a sloping loading ramp forms part of the extension of the collision bulkhead above the bulkhead deck of passenger ships and the freeboard deck of cargo ships, the ramp is to be weathertight over its complete length. In cargo ships the part of the ramp which is more than

2.3 m above the freeboard deck may extend forward of the limit specified in 1.12.3.1 and 1.12.3.2 of this Section. Ramps not meeting the above requirements are to be disregarded as an extension of the collision bulkhead.

1.12.3.6 The number of openings in the extension of the collision bulkhead above the freeboard deck is to be restricted to the minimum compatible with the design and normal operation of the ship. All such openings are to be capable of being closed weathertight.

1.12.4 Arrangement of after peak and machinery space bulkheads and stern tube

1.12.4.1 Bulkheads are to be fitted separating the machinery space from cargo and accommodation spaces forward and after and made watertight up to the bulkhead deck of passenger ships and the freeboard deck of cargo ships. An aft peak bulkhead is also to be fitted and made watertight up to the bulkhead deck or the freeboard deck. The aft peak bulkhead may, however, be stepped below the bulkhead deck or the freeboard deck, provided the degree of safety of the ship as regards subdivision is not thereby diminished.

1.12.4.2 In all cases, stern tubes are to be enclosed in watertight spaces of moderate volume. In passenger ships the stern gland is to be situated in a watertight shaft tunnel or other watertight space separate from the stern tube compartment and of such volume that, if flooded by leakage through the stern gland, the bulkhead deck will not be immersed. In cargo ships, other measures to minimize the danger of water penetrating into the ship in case of damage to stern tube arrangements may be taken upon approval.

1.12.5 Arrangement and watertightness of openings and trunks in watertight bulkheads and internal decks

1.12.5.1 The number of openings in watertight bulkheads is to be reduced to the minimum compatible with the design and proper working of the ship.

1.12.5.2 Where pipes, scuppers, electric cables, etc., are carried through watertight bulkheads, arrangements are to be made to ensure the watertight integrity of the bulkheads. Valves not forming part of a piping system are not to be permitted in watertight bulkheads. Lead or other heat-sensitive materials are not to be used in systems which penetrate watertight bulkheads.

1.12.5.3 For passenger ships, no doors, manholes or access openings are permitted in watertight transverse bulkheads dividing a cargo space from an adjoining cargo space, except those agreed. For cargo ships, CCS may permit relaxation of the watertightness requirements for openings above the freeboard deck, where it is demonstrated that any progressive flooding can be easily controlled and that the safety of the ship will not be thereby impaired.

1.12.5.4 No doors, manholes, ventilation ducts or any other openings are to be fitted in the collision bulkhead below the bulkhead deck for passenger ships (except the pipes, provided that the relevant requirements of the Administration are complied with).

1.12.5.5 Watertight ventilators and trunks are to be carried at least up to the bulkhead deck in passenger ships and up to the freeboard deck in cargo ships.

1.12.5.6 The arrangement and watertightness of accesses to spaces below the ro-ro deck (bulkhead deck) in ro-ro passenger ships are to comply with the following requirements:

(1) Subject to (2) and (3) of this paragraph, all accesses that lead to spaces below the bulkhead deck are to have a lowest point which is not less than 2.5 m above the bulkhead deck.

(2) Where vehicle ramps are installed to give access to spaces below the bulkhead deck, their openings are to be able to be closed weathertight to prevent ingress of water below, alarmed and indicated to the navigation bridge.

(3) CCS may permit the fitting of particular accesses to spaces below the bulkhead deck provided they are necessary for the essential working of the ship, e.g. the movement of machinery and stores, subject to such accesses being made watertight, alarmed and indicated to the navigation bridge.

1.12.6 Openings in the shell plating below bulkhead deck of passenger ships and the freeboard deck of cargo ships and their watertightness

1.12.6.1 The number of openings in the shell plating is to be reduced to the minimum compatible with the design and proper working of the ship.

1.12.6.2 Freeing ports are to be capable of rapidly freeing the decks of water and draining them. The freeing port area in bulwarks is to be in accordance with Regulation 24 of the Amendments to Annex I of Annex B to the Protocol of 1988 Relating to the International Convention on Load Lines, 1966.

1.12.6.3 Moving parts penetrating the shell plating below the deepest subdivision draught are to be fitted with an acceptable watertight sealing arrangement. The inboard gland is to be located within a watertight space of such volume that, if flooded, the bulkhead deck of passenger ships and the freeboard deck of cargo ships will not be submerged.

1.12.7 Other openings and their closing appliances

1.12.7.1 All access openings in bulkheads at ends of enclosed superstructures are to comply with the following requirements:

(1) Doors of steel or other equivalent material are to be fitted, permanently and strongly attached to the bulkhead, and framed, stiffened and fitted so that the whole structure is of equivalent strength to the un-pierced bulkhead and weathertight when closed.

(2) Unless otherwise permitted by the flag Administration, doors are to open outwards so as to be protected against wave impact.

(3) The height of doorsills is to be at least 380 mm above the deck.

1.12.7.2 Cargo and other hatchways, miscellaneous openings in freeboard and superstructure decks are to comply with the following requirements:

(1) The height of coamings of hatchways above the deck is to be at least as follows:

① 600 mm if in Position 1; and

② 450 mm if in Position 2.

(2) The structure of cargo and other hatchways in Positions 1 and 2 and the means for keeping them weathertight are to comply with the relevant requirements of Regulation 15 or 16 of the Amendments to Annex I of Annex B to the Protocol of 1988 Relating to the International Convention on Load Lines, 1966.

(3) Openings in freeboard and superstructure decks are to comply with the relevant requirements of Regulation 18 of the Amendments to Annex I of Annex B to the Protocol of 1988 Relating to the International Convention on Load Lines, 1966.

1.12.7.3 Machinery space openings are to comply with the following requirements:

(1) Machinery space openings are to be efficiently enclosed by steel casings. Access openings in such casings are to be fitted with weathertight doors, the sills of which are to be at least 600 mm above the deck if in Position 1, and at least 380 mm above the deck if in Position 2. Other openings in such casings are to be fitted with covers, permanently attached in their proper positions.

(2) Where machinery casings are not protected by other structures, double doors are to be required for ships assigned freeboards less than those based on relevant requirements. An inner sill of 230 mm in conjunction with the outer sill of 600 mm is to be provided.

(3) Coamings of any machinery space ventilator, the height of which complies with the requirements of 1.12.7.4(6) of this Section, need not be fitted with weathertight closing appliances. Ventilators necessary to continuously supply the emergency generator room, if this is considered buoyant in the stability calculation or protecting opening leading below, are to have coamings of sufficient height to comply with 1.12.7.4(6) of this Section, without having to fit weathertight closing appliances.

(4) Where the height of machinery space and emergency generator room ventilator coamings is less than that required by 1.12.7.4(6) of this Section, weathertight closing appliances are to be fitted.

(5) Engine/boiler openings are to be fitted with strong covers of steel or other equivalent material permanently attached in their proper positions and capable of being secured weathertight.

(6) Machinery casings on type "A" ships are to comply with the relevant requirements of Regulations 26(1) and (2) of the Amendments to Annex I of Annex B to the Protocol of 1988 Relating to the International Convention on Load Lines, 1966.

1.12.7.4 Ventilators are to comply with the following requirements:

(1) Ventilators in Position 1 or 2 to spaces below freeboard deck or decks of enclosed superstructures are to have coamings of steel or other equivalent material, substantially constructed and efficiently connected to the deck. Where the coaming of any ventilator exceeds 900 mm in height, it is to be specially supported.

(2) Ventilators passing through superstructures other than enclosed superstructures are to have substantially constructed coamings of steel or other equivalent material at the freeboard deck.

(3) Ventilators in Position 1 are to have coamings of a height of at least 900 mm above the deck.

(4) Ventilators in Position 2 are to have coamings of a height of at least 760 mm above the deck.

(5) The thickness of ventilator coamings may be taken from Table 1.12.7.4(5), but need not exceed that of the deck.

Thickness of Ventilator Coamings **Table 1.12.7.4(5)**

Internal diameter of coaming (mm)	Thickness of coaming (mm)	Internal diameter of coaming (mm)	Thickness of coaming (mm)
≤200	7.5	350	9.0
250	8.0	400	9.5
300	8.5	≥450	10.0

(6) Ventilators in Position 1 the coamings of which extend to more than 4.5 m above the deck, and in

Position 2 the coamings of which extend to more than 2.3 m above the deck, need not be fitted with closing arrangements.

(7) Except as provided in (6) above, ventilator openings are to be provided with efficient weathertight closing appliances. In ships of not more than 100 m in load line length L_L, the closing appliances are to be permanently attached; in ships of more than 100 m in load line length L_L, they may be conveniently stowed near the ventilators to which they are to be fitted.

1.12.7.5 Air pipes are to comply with the following requirements:

(1) Air pipes are to comply with the requirements of this Section and in addition, the relevant requirements of Chapter 3 of PART THREE of the Rules.

(2) Where air pipes to ballast and other tanks extend above the freeboard or superstructure decks, the height from the deck to the point where water may have access below is to be at least 760 mm on the freeboard deck and 450 mm on the superstructure deck. Where these heights may interfere with the working of the ship, a lower height may be approved, provided that CCS is satisfied that the closing arrangements and other circumstances justify a lower height. The exposed parts of the pipes are to be of substantial construction.

(3) The minimum wall thickness of air pipes above weather deck is to be:

6.0 mm for pipes of 80 mm external diameter or smaller;

8.5 mm for pipes of 165 mm external diameter or greater.

Intermediate minimum thicknesses are to be determined by linear interpolation.

(4) Air pipes are to be fitted with automatic closing devices.

1.12.8 Arrangement of double bottoms (not of tankers)

1.12.8.1 For all passenger ships regardless of size and cargo ships of 500 gross tonnage and over, a double bottom is to be fitted and is to extend from the collision bulkhead to the after peak bulkhead, as far as this is practicable and compatible with the design and proper working of the ship.

1.12.8.2 Where a double bottom is required to be fitted, the inner bottom is to be continued out to the ship's side in such a manner as to protect the bottom to the turn of the bilge. The vertical distance h measured from the keel line is in no case to be less than $B/20$, or less than 760 mm, whichever is the greater, and need not be greater than 2,000 mm.

1.12.8.3 Small wells constructed in the double bottom in connection with drainage arrangements are not to extend downward more than necessary. The vertical distance from the bottom of such a well to a plane coinciding with the keel line is not to be less than $h/2$ or 500 mm, whichever is greater. Other wells (e.g. for lubricating oil under main engines) may be permitted if satisfied that the arrangements give protection equivalent to that afforded by a double bottom complying with this regulation.

1.12.8.4 A double bottom need not be fitted in way of watertight tanks (including dry tanks) of moderate size, provided the safety of the ship is not impaired in the event of bottom or side damage.

1.12.8.5 Any part of a passenger ship regardless of size and a cargo ship of 500 gross tonnage and over that is not fitted with a double bottom in accordance with 1.12.8.1 or 1.12.8.4 of this Section is to satisfy the requirements for bottom damages, as specified in SOLAS II-1, in that part of the ship.

1.12.8.6 In case of large lower holds in passenger ships, the double bottom height is to be increased to not more than $B/10$ or 3 m, whichever is less, measured from the keel line. Alternatively, bottom damages may be calculated for these areas, in accordance with 1.12.8.5 of this Section, but assuming an increased vertical extent.

1.12.9 Arrangement of cofferdams

1.12.9.1 A cofferdam means an empty space arranged so that compartments on each side have no common boundary; a cofferdam may be located vertically or horizontally. A cofferdam is to be properly ventilated and of sufficient size to allow for inspection, maintenance and safety evacuation.

1.12.9.2 Cofferdams are to be provided between compartments intended for fuel oil or lubricating oil and those intended for fresh water (drinking water, water for propelling machinery and boilers).

Cofferdams are to be provided between compartments intended for fuel oil or lubricating oil and tanks

intended for the carriage of liquid foam for fire extinguishing.
Cofferdams are only required between fuel oil tanks in double bottom and tanks immediately above where the inner bottom plating is subjected to the head of fuel oil contained therein, as in the case of a double bottom with its top raised at the sides. Where a corner to corner situation occurs for such tanks, they are not considered to be adjacent.
1.12.9.3 In addition to the requirements of 1.12.9.2 of this Section, the oil fuel tank protection by means of cofferdams in ships is to comply with Regulation 12A of MARPOL Annex I.
1.12.9.4 The separation of cargo oil tanks in tankers is to be arranged in accordance with the requirements of SOLAS Reg. II-2/4.5 regarding cargo areas of tankers.
1.12.9.5 The arrangement of cofferdams is also to comply with 2.8.2 of Section 8, Chapter 2 of PART THREE of the Rules.

1.12.10 Arrangement of bow freeboard deck and compartments forward of collision bulkhead
1.12.10.1 The arrangement of bow freeboard deck and enclosed superstructures (if fitted) is to comply with the requirements for minimum bow height as specified in Regulation 39 of the Amendments to Annex I of Annex B to the Protocol of 1988 relating to the International Convention on Load Lines, 1966.
1.12.10.2 The arrangement of bow freeboard deck and enclosed superstructures (if fitted) of all ships assigned a type B freeboard, other than oil tankers, chemical tankers and gas carrier is to comply with 1.12.9.2 of this Section and in addition, the requirements for bow reserve buoyancy as specified in Regulation 39 of the Amendments to Annex I of Annex B to the Protocol of 1988 relating to the International Convention on Load Lines, 1966.
1.12.10.3 Fuel oil and other flammable oils are not to be carried in forepeak tanks and other compartments located forward of the collision bulkhead.
1.12.10.4 Chain lockers of ships with a load line length of 24 m and above are to comply with the following requirements:
(1) Spurling pipes and cable lockers are to be watertight up to the deck exposed to weather. However, the bulkhead between separate chain lockers (Figure 1.12.10.4(1)) or the common bulkhead between adjacent lockers (Figure 1.12.10.4(2)) need not be watertight.

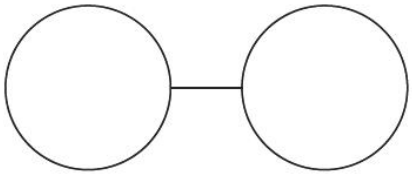

Figure 1.12.10.4(1)

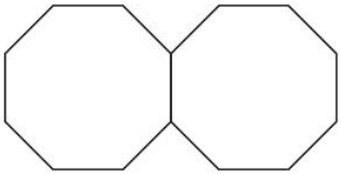

Figure 1.12.10.4(2)

(2) Where means of access are provided, they are to be closed by a substantial cover and secured by closely spaced bolts.
(3) Where a means of access to spurling pipes or cable lockers is located below the weather deck, the manhole covers and securing appliances are to be in consistence with recognized standards① , or equivalent to the watertight manhole covers. The use of butterfly nuts and/or hinged bolts as the securing appliances of manhole covers is prohibited.
(4) Spurling pipes through which anchor cables are led are to be provided with permanently attached closing appliances (e.g. steel plates in halves hooked over the spurling pipe tops, or canvas covers lashed) to minimize water ingress.

---

① E.g., 1) ISO 5894-2018; 2) China: CB/T4392-2014 “Marine manhole cover”; 3) India: IS 15876-2009 “Ship and Marine Technology manholes with bolted covers”; 4) Japan: JIS F2304:2015, “Ship’s Manholes” and JIS F2329:1975, “Marine Small Size Manhole”; 5) Korea: KS VISO 5894:2012; 6) Norway: NS 6260: 1985 “Manhole cover - overview” ; 7) Russia: GOST 2021-90 “Ship’s steel manholes, Specifications”.

1.12.11 Arrangement of passenger ships above the bulkhead deck

1.12.11.1 Measures are to be taken to limit the entry and spread of water above the bulkhead deck. Such measures may include partial bulkheads or webs. When partial watertight bulkheads and webs are fitted on the bulkhead deck, above or in the immediate vicinity of main subdivision bulkheads, they are to have watertight shell and bulkhead deck connections so as to restrict the flow of water along the deck when the ship is in a heeled damaged condition. Where the partial watertight bulkhead does not line up with the bulkhead below, the bulkhead deck between is to be made of effectively watertight.

1.12.11.2 All openings in the exposed weather deck are to have coamings of ample height and strength and are to be provided with efficient means for expeditiously closing them weathertight. Freeing ports, open rails and scuppers are to be fitted as necessary for rapidly clearing the weather deck of water under all weather conditions.

1.12.11.3 Air pipes terminating within a superstructure which are not fitted with watertight means of closure are to be considered as unprotected openings in damage stability calculation.

1.12.11.4 Side scuttles, gangway, cargo and coaling ports and other means for closing openings in the shell plating above the bulkhead deck are to be of efficient design and construction and of sufficient strength having regard to the spaces in which they are fitted and their positions relative to the deepest subdivision draught.

1.12.11.5 Efficient inside deadlights, so arranged that they can be easily and effectively closed and secured watertight, are to be provided for all side scuttles to spaces below the first deck above the bulkhead deck.

1.12.12 Arrangement of compartments of double hull oil tankers

1.12.12.1 Wing tanks or spaces are to extend either for the full depth of the ship's side or from the top of double bottom to the uppermost deck, disregrading a rounded gunwale where fitted. They are to be so arranged that all cargo tanks are located inboard of the moulded lines of the side shell plating in those tanks or spaces. The entire cargo tank (including slop tank) length of oil tankers of 5,000 tons deadweight and above are to be protected by ballast tanks or spaces other than tanks that carry oil, and the wing tanks and double bottom for such protection within the cargo tank length are to comply with the following requirements:

(1) The vertical distance W between wing tank inner hull and side shell is not to be less than as calculated below:

$W = 0.5 + DW/20000$ m or

$W = 2.0$ m

whichever is the lesser. The minimum value of W = 1.0 m.

where: DW (Deadweight) means the difference in tons between the displacement of a ship in water of a relative density of 1.025 t/m^3 at the load line corresponding to the assigned summer freeboard and the lighweight of the ship.

(2) The depth of double bottom is not to be less than as calculated below:

$h = B/15$ m or

$h = 2.0$ m

whichever is the lesser. The minimum value of h = 1.0 m.

1.12.12.2 The height of double bottom of oil tankers of less than 5,000 tons deadweight are to comply with the following requirements:

$h = B/15$ m; the minimum value of h = 0.76 m

1.12.12.3 Every crude oil tanker of 20,000 tons deadweight and above and every product carrier of 30,000 tons deadweight and above are to be provided with segregated ballast tanks. The capacity of the segregated ballast tanks is to be so determined that the ship may operate safely on ballast voyages without recourse to the use of cargo tanks for water ballast. The capacity of segreated ballast tanks is to be at least such that, in any ballast condition at any part of the voyage, including the conditions consisting of lightweight plus segregated ballat only, the ship's draughts and trim can meet the following requirements:

(1) the moulded draught amidship (d_m), in m, (without taking into account any defomation of the ship) is not to be less than:

$$d_m = 2.0 + 0.02L_L \quad \text{m}$$

(2) the draughts at the forward and after perpendiculars are to correspond to those determined by the draught amidships as specified in (1) above, in association with the trim by the stern of not greater than $0.015L_L$; and

(3) the draught at the after perpendicular is not to be less than that which is necessary to obtain full immersion of the propeller(s).

1.12.12.4 Cargo tanks are to be of such size and arrangement that the hypothetical oil outflow from side and bottom damage, anywhere in the length of the ship, is limited.

For oil tankers of less than 5,000 tons deadweight, the length of each cargo tank is not to exceed 10 m or one of the following values, whichever is the greater:

(1) where no longitudinal bulkhead is provided inside the cargo tanks: $(0.5b_i/B + 0.1)L_L$, but not to exceed $0.2\ L_L$;

(2) where a centerline longitudinal bulkhead is provided inside the cargo tanks: $(0.25b_i/B + 0.15)L_L$;

(3) where two or more longitudinal bulkheads are provided inside the cargo tanks:

① for wing cargo tanks: $0.2\ L_L$

② for centre cargo tanks:

(a) if b_i/B is equal to or greater than 1/5: $0.2\ L_L$

(b) if b_i/B is less than 1/5:

(i) where no centerline longitudinal bulkhead is provided: $(0.5b_i/B + 0.1)L_L$

(ii) where a centerline longitudinal bulkhead is provided: $(0.25b_i/B + 0.15)L_L$

b_i is the minimum distance from the ship's side to the outer longitudinal bulkhead of the tank in question measured inboard at right angles to the centerline at the level corresponding to the assigned summer freeboard.

For oil tankers of less than 5,000 tons deadweight, the capacity of each cargo tank is not to exceed 700 m^3, unless wing tanks or spaces are arranged in accordance with 1.12.12.1(1), complying with the following:

$W = 0.4 + 2.4DW/20000$ m; the minimum value of $W = 0.76$ m.

1.12.12.5 For oil tankers carrying oil having a flash point not exceeding 60℃, the separation of cargo tanks is to comply with the following requirements: Cargo pump-rooms, cargo tanks, slop tanks and cofferdams are to be positioned forward of machinery spaces. Main cargo control stations, control stations, accommodation and service spaces are to be positioned aft of cargo tanks, slop tanks, and spaces which isolate cargo or slop tanks from machinery spaces, but not necessarily aft of fuel oil tanks and ballast tanks.

1.12.12.6 Cofferdams are to be at least gastight. If applicable, means of access for internal inspection are to comply with 1.12.14 to 1.12.16 of this Section.

1.12.12.7 For oil tankers of 5,000 tons deadweight and above, the pump-room is to be provided with a double bottom such that at any cross-section the depth of each double bottom tank or space is to be such that the distance between the bottom of the pump-room and the ship's baseline measured at right angles to the ship's baseline is not less than specified below:

B/15 m or 2 m,

whichever is the lesser.The minimum value is 1 m.

In case of pumo-rooms whose bottom plate is located above the baseline by at least the minimum height required above (e.g. gondola stern design), there will be no need for a double bottom construction in way of the pump-room.

1.12.13 Arrangement of compartments of single hull oil tankers

1.12.13.1 Oil tankers of 600 tons deadweight and above but less than 5,000 tons deadweight are to be fitted with double bottom tanks or spaces, the height of which is to comply with the requirement of 1.12.12.2 of this Section.

1.12.13.2 Oil tankers of less than 600 tons deadweight are not necessarily to be fitted with double bottom and double hull.

1.12.13.3 The length of cargo tanks is to comply with the requirements of 1.12.12.4 of this Section for oil tankers of less than 5,000 tons deadweight.
1.12.13.4 The segregation of cargo tanks is to comply with the requirements of 1.12.12.5 of this Section.

1.12.14 Access and its openings and other requirements

1.12.14.1 Oil tankers as defined in Regulation II-1/2, chemical tankers as defined in Regulation VII/8.2 and gas carriers as defined in Regulation VII/11.2 of the International Convention for the Safety of Life at Sea, 1974, as amended are to be fitted with safe access to bow in accordance with Regulation II-1/3-3 of the Convention.
1.12.14.2 Oil tankers of 500 gross tonnage and over and bulk carriers (as defined in Regulation IX/1 of the International Convention for the Safety of Life at Sea, 1974, as amended) of 20,000 gross tonnage and over are to be fitted with access to and within spaces in, and forward of, the cargo area in accordance with Regulation II-1/3-6 of the Convention.
1.12.14.3 When implementing the provisions of 1.12.14.1 and 1.12.14.2 of this Section, for oil tankers of less than 5,000 tons deadweight, openings of smaller dimesions may be provided subject to the agreement of the flag State Administration, provided that the ability to traverse such openings or to remove an injured person can be proved. However in any case, the size of openings is not to be less than 400 mm × 600 mm or 450 mm × 550 mm.
1.12.14.4 In addition to the requirements of 1.12.14.1 to 1.12.14.3 of this Section, all ships are to be fitted with safe passage of crew in accordance with Regulation 25-1 of the Amendments to Annex I of Annex B to the Protocol of 1988 relating to the International Convention on Load Lines, 1966. Gangway and access fitted on type "A" ships are to be in accordance with Regulations 26(3) and (4) of Annex I. In addition, all ships are to be fitted with guard rails and bulwarks as means for protection of the crew in accordance with Regulations 25(2) and (3) of Annex I.

1.12.15 Arrangement of fuel oil tanks

1.12.15.1 Fuel oil tanks are to be arranged in accordance with the requirements of Regulation 12A of MARPOL Annex I.

Section 13 MARKING OF OPERATING DRAFT OF WORKING SHIPS

1.13.1 General provisions

1.13.1.1 This Section applies to floating cranes, and to open hopper dredgers and barges fitted with means of opening at their bottom (these three types of ships are hereinafter referred to as working ship).
1.13.1.2 For working ships, the maximum operating draught may be assigned and such draught appropriately marked in accordance with this Section.
1.13.1.3 In operational areas defined by the limited sea conditions in 1.13.3 of this Section, the process of hoisting and handling operations of floating cranes, that of dredging operations of dredgers and that of loading, carrying and discharging operations of dredgers and barges are considered as their operating conditions.
1.13.1.4 The intact stability of working ships in operating conditions is to comply with the requirements of 1.13.4 of this Section, or alternatively, their compliance with the requirements of the flag Administration for intact stability regarding assignment of operating draught is to be confirmed.

1.13.2 Assignment of operating draught

1.13.2.1 For working ships intended for assignment of operating draught, the maximum operating draught is to be assigned in accordance with this Chapter, based on the minimum summer freeboard corresponding to type B freeboard as specified in the amendments to the protocol of 1988 relating to the International Convention on Load Lines, 1966 (IMO resolution MSC.143(77)).

1.13.2.2 Where all requirements of this Section are complied with, the maximum draught of working ships in operation may correspond to a freeboard reduced by 2/3 of the minimum summer freeboard referred to in 1.13.2.1.

1.13.3 Limitations on sea conditions for operations

1.13.3.1 For working operations at the maximum operating draught assigned in accordance with this Section, limitations on sea conditions for areas, in which the working ship is to operate, are as follows:

(1) For floating cranes, wind force is not to exceed Beaufort scale 5 and significant wave height is not to exceed 1 m.

(2) For dredgers and barges, wind force is not to exceed Beaufort scale 6 and significant wave height is not to exceed 2 m.

1.13.3.2 Where the environmental limitations as required by design regarding wind and wave for sea areas, in which working ships are to operate, are beyond those specified in 1.13.3.1, relevant technical proof and calculations or model test information for ensuring safe operation are to be submitted for approval or agreement by CCS. And this is to be indicated in the operating draught marking instruction in accordance with 1.13.6.3 of this Section.

1.13.4 Intact stability in operating condition

1.13.4.1 The intact stability of floating cranes in operating condition is to comply with the following requirements:

(1) The stability of floating cranes is to be checked for the following loading conditions:

① maximum lifting load, necessary ballast and all fuels and stores, the ship being at the maximum operating draught;

② maximum lifting load, necessary ballast and 10% of fuels and stores.

(2) Initial metacentric height GM of floating cranes in operating condition:

$$GM \geq \frac{M_f + M_h}{0.1716\theta_c \Delta} \quad \text{m}$$

where: GM — initial metacentric height, in m, taking into account the effects of free surface and suspended objects thereon;

M_f — heeling moment due to wind pressure on the floating crane, in kN·m, calculated according to 1.13.4.2;

M_h — heeling moment due to maximum lifting load and heeling moment due to asymmetrical loading, if any, in kN · m;

θ_c — permissible static limiting heeling angle, (°), taken as 4/5 immersion angle of freeboard deck edge, 4/5 emersion angle of bilge or heeling angle corresponding to 0.3 m of residual freeboard, whichever is the least; not exceeding 5° for floating cranes with slewing booms, and not exceeding 3° for floating cranes with unslewing booms;

Δ — displacement in the loading condition under checking, in t.

(3) Stability criterion numeral K of floating cranes in operating condition:

$$K = \frac{9.81 l_q \Delta}{M_f + M_h} \geq 1$$

where: l_q — minimum capsizing lever, in m, without taking into account the effect of rolling;

Δ, M_f, M_h — the same as in (2).

1.13.4.2 The heeling moment M_f due to wind pressure on the floating crane in operating condition is to be calculated as follows:

$$M_f = 0.001 P \sum C_i A_{f_i} Z_i \quad \text{kN} \cdot \text{m}$$

where: P — wind pressure calculated per unit, taken as 170 N/m^2;

C_i — coefficient for correction of height, as given in Table 1.13.4.3;

A_{fi} — windage area, in m^2;

Z_i — vertical distance, in m, from centre of windage area A_{fi} to half draught d in the loading condition under checking;

Δ — displacement in the loading condition under checking, in t.

Coefficient C_i for Correction of Height **Table 1.13.4.3**

Z_i - d/2 (m)	0 ~ 15	15 ~ 30	30 ~ 45	45 ~ 60	60 ~ 75	75 ~ 90	90 ~ 105	105 ~ 120
C_i	1.00	1.16	1.32	1.44	1.53	1.61	1.68	1.74

1.13.4.3 The intact stability of dredgers and barges in operating condition is to comply with the following requirements:

(1) The stability of dredgers and barges in operating condition is to be checked for the following loading conditions:

① hopper fully loaded, with all fuels and stores;

② hopper fully loaded, with 10% of fuels and stores;

③ hopper partially loaded, with 10% of fuels and stores;

④ hopper unloaded, but being open to sea, with all fuels and stores;

⑤ hopper unloaded, but being open to sea, with 10% of fuels and stores.

When the hopper is fully loaded, spoil is to be loaded to the lower edge of the opening of the means for overflow specified in 1.13.5.2, and the least of the values obtained is to be taken.

When the hopper is partially loaded, an additional layer of seawater is to be assumed on the top of spoil to reach the lower edge of the opening of the means for overflow specified in 1.13.5.2, and the least of the values so obtained is to be taken.

(2) The density of spoil in hopper is to be taken as follows:

① the stability with the density of spoil ρ_{m1}, ρ_{m2} at the maximum operating draught according to (1)①, ② is to be checked;

② the stability is to be checked according to (1)②, density of spoil $\rho = 1.4 – 0.2\ i$, in t/m^3, (i = 0, 1, 2) whichever is the closest to and less than ρ_{m2};

③ the stability is to be checked according to (1)③, density of spoil $\rho = 2.2 – 0.2\ i$, in t/m^3, (i = 0, 1…6) whichever is the closest to and over ρm_2,

where at the maximum operating draught, an additional layer of seawater on the top of spoil is to be regarded as overload.

(3) Characteristic values of righting lever curves for dredgers and barges in operating condition:

① the initial metacentric height is not to be less than 0.15 m;

② the righting lever GZ is to be at least 0.2 m at heeling angles equal to or over 30°;

③ the heeling angle θ_{max} corresponding to the maximum righting lever is to be not less than 15°;

④ up to the heeling angle θ_{max} corresponding to the maximum righting lever, the area under the righting lever curve (GZ curve) is to be not less than 0.055 + 0.001 (30° – θ_{max}) m · rad, and θ_{max} is taken as 30° if greater than 30°;

⑤ the area under the righting lever curve (GZ curve) between the heeling angles of 30° and 40°, or between 30° and immersion angle θ_f (if this angle is less than 40°) is not to be less than 0.03 m · rad.

(4) Weather criterion for dredgers and barges in operating condition:

The weather criterion in 2.3, Chapter 2, Part A of the International Code on Intact Stability, 2008 (2008 IS Code) is to be complied with, where the wind pressure is taken as 215 N/m^2 and the angle of roll may be reduced by 20% but not less than 10°.

(5) For stability calculation, where the density of spoil in the hopper is equal to or less than 1.4 t/m^3, the effects of free surface of spoil on the initial metacentric height and righting lever curves are to be calculated and in this case, the outflow of liquid spoil and inflow of seawater over the upper edge of the hopper coaming by ship's heeling may be taken into account. Where the density of spoil in the hopper is greater than 1.4 t/m^3, the inflow and outflow of seawater through the lower edge of the opening of the means for overflow specified in 1.13.5.2 (and the least of the values obtained is to be taken) by ship's heeling is to be

taken into account. The righting lever curves are to be calculated according to the actual changes of displacement and of centre of gravity of spoil.

(6) For dredgers and barges with bottom doors or similar opening means for the hopper, asymmetric discharging, which is possible due to failure of control mechanism of the door or other opening means, is to be taken into account. 20% of the total hopper load is to be assumed to be discharging only at one side of the longitudinal centre line of the hopper, horizontally and equally distributed at the discharging side, according to the loading condition and the density of spoil respectively specified in (1)② and (2)① above. In this situation, the stability is to comply with the following requirements:

① the angle of equilibrium is not to exceed 25°;

② the range of positive righting lever beyond the angle of equilibrium is not to be less than 30°;

③ the righting lever *GZ* within the range of positive righting lever beyond the angle of equilibrium is to be at least 0.1 m.

(7) Working ships intended for operations in icing areas are to comply with the relevant requirements in Chapter 6, Part B of the International Code on Intact Stability, 2008 (2008 IS Code).

1.13.5 Special requirements for assigning operating draught of dredgers and barges

1.13.5.1 No bulwark is to be fitted on the freeboard deck abreast of any hopper which is an open hopper.

1.13.5.2 Means for overflow of process water is to be arranged for open hoppers as follows:

(1) through the overflow opening of the hopper coaming, the area of which at each side of the coaming is not to be less than 5% of that of that side of the coaming; or

(2) through overflow ducts in the hopper walls, the area of which at each side is not to be less than 0.35 $(L_h)^2/1000$ m^2, or $Q/6$ m^2, whichever is the greater,

where L_h is the maximum length of the hopper, in m;

Q is the total maximum water capacity of the suction dredge pumps, in m^3/sec; or

(3) through adjustable overflows, the area of which at each side is as given in (2) above; or

(4) using upper edge of hopper coaming as overflow opening.

1.13.5.3 In respect to the requirements for piping and valves used in discharging water overboard and the requirements for location of side scuttles or doors, the maximum operating draught is to be considered the uppermost load line or summer load waterline.

1.13.5.4 The spoil dumping system at bottom of the hopper is to be capable of discharging the spoil by gravity, such that the ship is to increase its draught from the maximum operating draught to the summer load waterline within 8 minutes using normal operation of the dumping system.

1.13.5.5 An accurate draught indicator, capable of showing fore, aft and midship draught, is to be fitted at the navigating bridge.

1.13.6 Operating draught mark

1.13.6.1 The permissible maximum operating draught line is to be permanently marked on both sides of the working ship, placed 540 mm aft of the centre of the load line mark. The maximum operating draught mark is to be a line of 25 mm in width and 450 mm in length. The upper edge of the line is to be flush with the maximum operating draught line. The operating draught is indicated by the letter W above the left end and the letter D above the right end of that line, each measuring 115 mm in height and 75 mm in width, as shown in Figure 1.13.6.1.

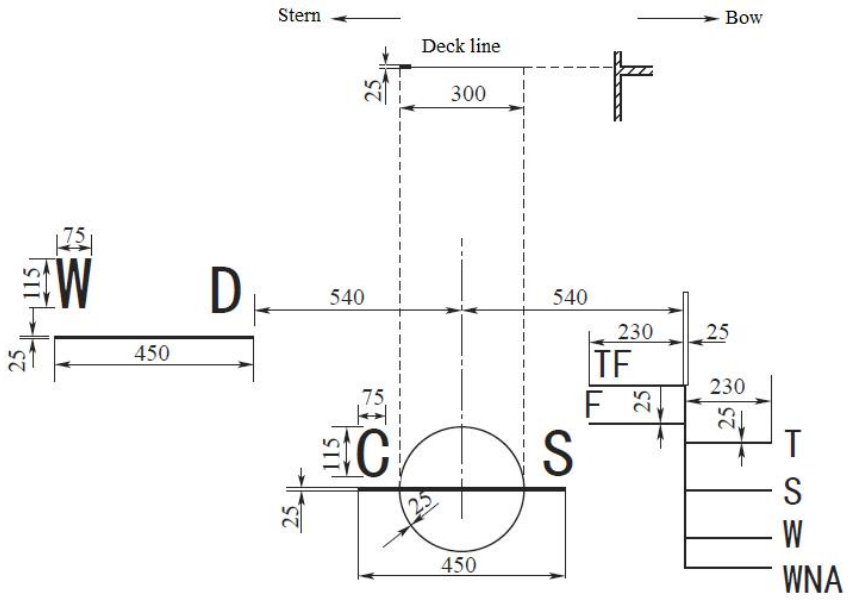

Figure 1.13.6.1 Operating Draught Mark (Starboard)

1.13.6.2 Prior to marking the maximum operating draught of a working ship, compliance of the ship with the stability requirements and other special requirements for operation of working ships is to be confirmed and indicated in the instruction for marking operating draught.

1.13.6.3 Limitations on sea conditions for operations of the working ship are to be clearly defined, compliance of the ship with the stability requirements and other special requirements for its operation summarized in the instruction for marking operating draught, and a marking sketch showing the maximum operating draught line is to be attached thereto.

CHAPTER 2 HULL STRUCTURES

Section 1 GENERAL PROVISIONS

2.1.1 Application

2.1.1.1 This Chapter applies mainly to dry cargo ships. If not covered in this Chapter, the requirements of Chapter 1 of this PART are to be complied with.

2.1.1.2 This Chapter applies to the basic structural configuration of a multi-deck or a single deck hull which includes a double bottom, or a single bottom arrangement, and with the hatch openings of normal dimensions.

2.1.1.3 Longitudinal framing is in general to be adopted at the strength deck outside the line of openings and at the bottom.

2.1.1.4 For ships with self-unloading system, such system is to meet the relevant requirements of CCS Rules for Lifting Appliances of Ships and Offshore Installations.

2.1.2 Class notations

2.1.2.1 General dry cargo ships complying with the requirements of this Chapter will be assigned the class notation General Dry Cargo Ship.

2.1.2.2 Ships which have been strengthened for heavy cargoes and comply with the requirements of Section 22 of this Chapter will be assigned the class notation Strengthened for Heavy Cargoes.

2.1.2.3 Ships which have been strengthened for grabs and comply with the requirements of Section 23 of this Chapter will be assigned the class notation Grab*(X).

2.1.2.4 Ships which comply with the requirements of Section 14, Chapter 8 of this PART will be assigned the class notation Double Side Skin.

2.1.2.5 General dry cargo ships intended to carry cargoes in bulk may be assigned the notation Maximum cargo density x.y t/m^3. When the maximum density of the bulk cargo designed under the bulk cargo loading condition is less than 3.0 t/m^3, this notation is assigned to indicate the limitation and the maximum density value of the bulk cargo allowed to be loaded, see Section 12, Chapter 8 of this PART for detailed requirements.

2.1.2.6 General dry cargo ships intended to carry cargoes in bulk may be assigned the notation No MP. This notation is assigned to show the limitation when the bulk cargo loading condition of general dry cargo ships has not been designed for loading and unloading in multiple ports in accordance with the Rules, see Section 12, Chapter 8 of this PART for detailed requirements.

2.1.2.7 General dry cargo ships intended to carry cargoes in bulk may be assigned the notation Holds a, b, …may be empty. This notation is assigned to specify the empty hold No. when specified empty holds are allowed in the design of bulk cargo loading condition of general dry cargo ships, see Section 12, Chapter 8 of this PART for detailed requirements.

2.1.3 Plans and documents

2.1.3.1 Plans and documents covering the following items are to be submitted to CCS for approval. In the case of special constructions and arrangements, additional plans and documents may be required if considered necessary by CCS:

(1) Principal transverse sections;

(2) Construction profile, including longitudinal sections, decks, inner bottom, superstructures and deckhouses;

(3) Stem;

(4) Stern frame;

(5) Shell expansion;

(6) Oiltight and watertight bulkheads;

(7) Main engine seating and thrust bearing seating;

(8) Propeller shaft bracket;

(9) Hatch coamings;

(10) Cargo hatch covers;

(11) Arrangement of anchoring equipment including equipment number calculations;

(12) Rudder, rudder stock and tiller;

(13) Masts, derrick posts and crane pedestals, together with their support structures;

(14) Ice strengthening with calculations;

(15) Welding, including type and size of welds;

(16) Preliminary and finished loading manuals.

2.1.3.2 The following plans and documents are to be submitted to CCS for information:

(1) General arrangement;

(2) Lines or offsets;

(3) Body plan (frame lines);

(4) Capacity plan;

(5) Specifications for hull and equipment;

(6) Longitudinal strength calculations (where applicable);

(7) Direct strength calculation report (where applicable);

(8) Fatigue strength assessment report (where applicable).

2.1.4 Direct strength calculation and fatigue strength assessment for hull structure

2.1.4.1 For general dry cargo ships of 150 m or over in length, FE direct strength calculation and verification are to be carried out for the strength of primary structural members within cargo area. When containers are carried, reference may be made to applicable requirements of Appendix 2, Chapter 7 of this PART. When bulk cargoes are carried, reference may be made to applicable requirements of Appendix 1, Chapter 8 of this PART.

2.1.4.2 For general dry cargo ships of 150 m or over in length, the fatigue strength check may be carried out for the following structural members in the cargo area. For check method, reference may be made to CCS Guidelines for Fatigue Strength of Ship Structure:

(1) connections of longitudinals (bottom, side, deck and inner shell) to transverse web frames;

(2) connections of longitudinals (bottom, side, deck and inner shell) to transverse bulkheads;

(3) connections of hopper tank sloping plate or inner shell to inner bottoms (if any);

(4) connections of transverse bulkheads to inner bottoms and girders.

Section 2 LONGITUDINAL STRENGTH

2.2.1 General requirements

2.2.1.1 For ships of 65 m and over in length, their longitudinal strength is to be checked in accordance with the requirements of this Section. For ships of unusual type or special loading and less than 65 m in length, their longitudinal strength may also be checked in accordance with the requirements of this Section.

For container ships of 90 m and over in length or ships dedicated primarily to carry their load in containers, their longitudinal strength is to comply with the requirements of Section 2, Chapter 7 of this PART and of 2.2.5.1 of this Section.

2.2.1.2 For ships complying with the following conditions, special considerations are required for longitudinal strength:

(1) For ships having one or more of the following characteristics, direct calculations are in general to be carried out, of which, direct calculation of wave loads is given in 2.2.9 of this Section:

$L/B \leq 5$

$B/D \geq 2.5$

$L \geq 500$ m

$C_b < 0.6$

(2) For ships having large deck openings, the longitudinal strength at combined bending and torque is to be checked according to the requirements in Section 10, Chapter 7 of this PART.

(3) For ships having large flare, additional bending moment caused by slamming may be considered.

(4) For ships intended for the carriage of special cargoes (e.g. heated cargoes), ships of unconventional type or ships of unconventional design, direct calculations are to be carried out in accordance with properties of cargoes or ship's type; where direct calculations are impracticable, design loads are to be determined by means of model test.

2.2.2 Design still water bending moment and shear force

2.2.2.1 The still water bending moment and shear force at each transverse section along the ship's length are to be calculated from the following conditions:

In loaded conditions: departure, arrival;

In ballast conditions: departure, arrival.

Various loading conditions included in the Loading Manual are also to be taken into account in the calculation.

2.2.2.2 In calculation of still water bending moments and shear forces, the downward loads are to be taken as positive values, the upward loads as negative values, and are to be integrated in the forward direction from the aft end of the length of the ship. The sign conventions of the still water bending moments M_s and shear forces F_s are as shown in Figure 2.2.2.2.

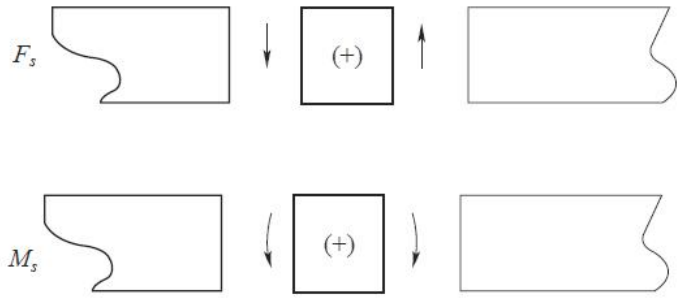

Figure 2.2.2.2

2.2.2.3 In general, the following design cargo and ballast loading conditions, based on amount of bunker, fresh water and stores at departure and arrival, are to be considered for the M_s and F_s calculations.

Where the amount and disposition of consumables at any intermediate stage of the voyage are considered more severe, calculations for such intermediate conditions are to be submitted for information. Also, where any ballasting and/or deballasting is intended during voyage, calculations of the intermediate condition just before and just after ballasting and/or deballasting any ballast tank are to be submitted and where reviewed included in the loading manual for guidance.

(1) General cargo ships, container ships, roll-on/roll-off and refrigerated cargo carriers, bulk carriers, ore carriers:

① homogeneous loading conditions at maximum draught;

② ballast conditions;

③ special loading conditions, e.g. container or light load conditions at less than the maximum draught, heavy cargo, empty holds or non-homogeneous cargo conditions, deck cargo conditions, etc., where applicable;

④ short voyage or harbor conditions, where applicable;

⑤ docking condition , afloat;

⑥ instantaneous conditions of loading and unloading, where applicable;

⑦ for bulk carriers to which the harmonized class notation BC-A, BC-B or BC-C is assigned in accordance with the requirements of Section 12, Chapter 8 of this PART, conditions specified in 8.12.4 of Section 12, Chapter 8 of this PART are also to be calculated.

(2) Oil tankers:

① homogeneous loading conditions (excluding dry and clean ballast tanks) and ballast or part-loaded conditions;

② any specified non-uniform distribution of loading;

③ mid-voyage conditions relating to tank cleaning or other operations where these differ significantly from the ballast conditions;

④ docking condition, afloat;

⑤ instantaneous conditions of loading and unloading, where applicable.

(3) Chemical tankers:

① conditions as specified for oil tankers;

② conditions for high density or segregated cargo.

(4) Liquefied gas carriers:

① homogeneous loading conditions for all approved cargoes;

② ballast conditions;

③ cargo condition where one or more tanks are empty or partially filled or where more than one type of cargo having significantly different densities are carried;

④ harbor conditions where increased steam pressure is approved;

⑤ docking condition, afloat.

(5) Combination carriers:

① conditions as specified for oil tankers and cargo ships.

2.2.2.4 Where the typical condition during ballast water exchange at sea is to be taken into account, reference may be made to the Guidelines for the Preparation of Ship's Ballast Water Management Plan.

2.2.2.5 Partially filled ballast tanks in ballast loading conditions (relevant recommendations are given in Appendix 3 of this Chapter)

Ballast loading conditions involving partially filled peak and/or other ballast tanks at departure, arrival or during intermediate conditions are not permitted to be used as design conditions unless:

- design stress limits are satisfied for all filling levels between empty and full, and
- for bulk carriers, the requirements in Section 8, Chapter 8 of this PART, as applicable, are complied with for all filling levels between empty and full.

To demonstrate compliance with all filling levels between empty and full, it will be acceptable if, in each condition at departure, arrival and where required by 2.2.2.3 of this Section, any intermediate condition, the tanks intended to be partially filled are assumed to be:

- empty;
- full;
- partially filled at intended level.

Where multiple tanks are intended to be partially filled, all combinations of empty, full or partially filled at intended level for those tanks are to be investigated.

However, for conventional ore carriers with large wing water ballast tanks in cargo area, where empty or full ballast water filling levels of one or maximum two pairs of these tanks lead to the ship's trim exceeding one of the following conditions, it is sufficient to demonstrate compliance with maximum, minimum and intended partial filling levels of these one or maximum two pairs of ballast tanks such that the ship's condition does not exceed any of these trim limits. Filling levels of all other wing ballast tanks are to be considered between empty and full. The trim conditions mentioned above are:

- trim by stern of 3% of the ship's length, or
- trim by bow of 1.5% of ship's length, or
- any trim that cannot maintain propeller immersion (I/D) not less than 25%, where:

I — the distance from propeller centerline to the waterline;

D — propeller diameter (see Figure 2.2.2.5).

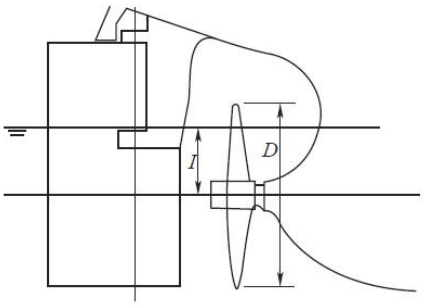

Figure 2.2.2.5

The maximum and minimum filling levels of the above mentioned pairs of side ballast tanks are to be indicated in the loading manual.

2.2.2.6 Partially filled ballast tanks in cargo loading conditions

In cargo loading conditions, the requirements in 2.2.2.5 of this Section apply to the peak tanks only.

2.2.2.7 Sequential ballast water exchange

Requirements of 2.2.2.5 and 2.2.2.6 of this Section are not applicable to ballast water exchange using the sequential method. However, bending moment and shear force calculations for each de-ballasting or ballasting stage in the ballast water exchange sequence are to be included in the loading manual or ballast water management plan of any ship that intends to employ the sequential ballast water exchange method.

2.2.3 Wave bending moment and wave shear force

2.2.3.1 The hogging and sagging wave bending moments $M_W(+)$ and $M_W(-)$ at each transverse section along the ship's length are to be obtained from the following formulae:

$$M_W(+) = +190MCL^2BC_b \times 10^{-3} \qquad \text{kN·m}$$

$$M_W(-) = -110MCL^2B(C_b + 0.7) \times 10^{-3} \qquad \text{kN·m}$$

where: M — distribution factor of bending moment, see Figure 2.2.3.1;

L — length of ship, in m;

B — breadth of ship, in m;

C_b — block coefficient, taken not less than 0.60;

C — coefficient to be obtained from the following formulae:

$C = 0.0412L + 4$ for $L < 90$ m;

$C = 10.75 - \left(\frac{300 - L}{100}\right)^{3/2}$ for $90 \le L \le 300$ m;

$C = 10.75$ for $300 < L < 350$ m;

$C = 10.75 - \left(\frac{L - 350}{150}\right)^{3/2}$ for $350 \le L \le 500$ m.

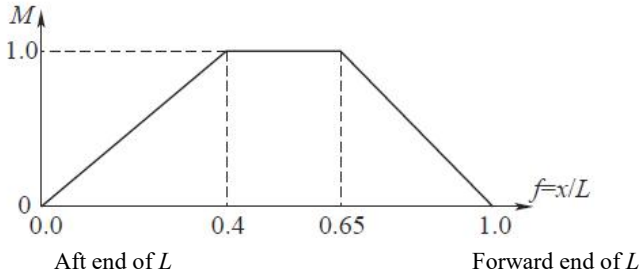

Figure 2.2.3.1

2.2.3.2 The hogging and sagging wave shear forces F_w (+) and F_w (−) at each transverse section along the ship's length are to be obtained from the following formulae:

$$F_w(+) = +30F_1CLB(C_b + 0.7)\times 10^{-2} \quad \text{kN}$$

$$F_w(-) = -30F_2CLB(C_b + 0.7)\times 10^{-2} \quad \text{kN}$$

where: F_1, F_2 — shear force distribution factor given in Figure 2.2.3.2(1) and Figure 2.2.3.2(2);

C — coefficient to be obtained from 2.2.3.1 of this Section;

C_b — see 2.2.3.1 of this Section;

L — length of ship, in m;

B — breadth of ship, in m.

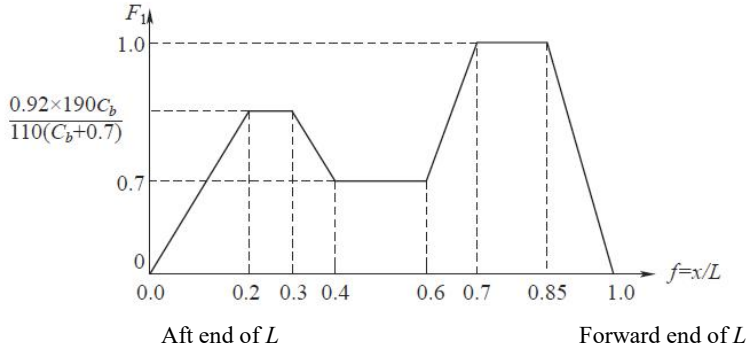

Figure 2.2.3.2(1)

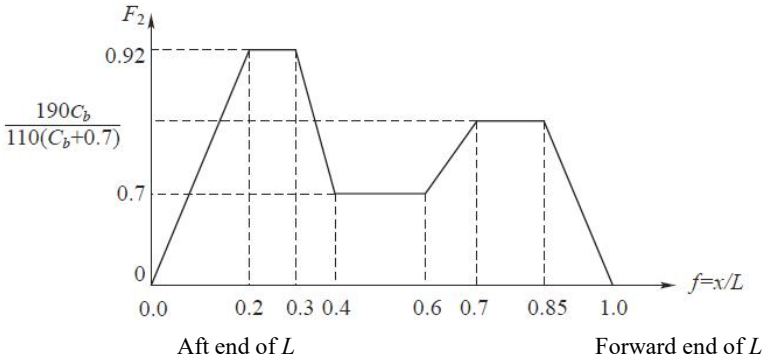

Figure 2.2.3.2(2)

2.2.4 Calculation of hull girder section properties

2.2.4.1 The moment of inertia of the hull girder section about its horizontal neutral axis divided by the vertical distance from the neutral axis to the top of strength deck at side gives the hull girder section modulus W_d at the strength deck; and that divided by the vertical distance from the neutral axis to the top of keel gives the hull girder section modulus W_b at bottom.

2.2.4.2 The strength deck and all continuous longitudinal members below the strength deck within 0.4L amidships may be included in the calculation of hull girder section modulus. The extension of the sheer strake above the strength deck and the continuous stringer angles may be included in the calculation. Where trunck decks or continuous hatch coamings (except inboard coamings of multi-hatch arrangements) above the strength deck are effectively supported by longitudinal bulkheads or deep girders, their sectional area may also be included in the calculation of the hull girder section modulus.

2.2.4.3 For multi-hatch arrangements, the effective sectional area for the inboard continuous hatch coaming and supporting members below is to be determined by direct calculation in accordance with support conditions. The following provision is applicable to cases without detailed calculation:

(1) Where a continuous longitudinal underdeck girder, or girders, are arranged to support the inboard hatch coamings, 50% of their sectional area are to be included in the calculation of the hull girder section modulus. If the girder is fitted in conjunction with a longitudinal bulkhead, 100% of the sectional area may be included. In cases where the girders are enclosed box sections, or where the girders are not enclosed box sections and are adequately supported and effectively tied to the bottom structure, 80% of their sectional area may be included. The slender ratio of the above-mentioned girders is not to be greater than 60.

(2) The percentage of the sectional area to be included for inboard continuous hatch coamings is to be the same percentage as that of the longitudinal girder under.

2.2.4.4 For the cases in 2.2.4.2 and 2.2.4.3 of this Section, when calculating the hull girder section modulus, the lever Z_t, vertical distance from the point considered to the neutral axis, is to be taken as follows, with Z_t being greater than the vertical distance from the neutral axis to the moulded deck line at side:

$$Z_t = Z_c \left(0.9 + 0.2\frac{y}{B_1}\right) \quad \text{m}$$

where: Z_c — vertical distance from the neutral axis to the top of the continuous strength member, in m;

y — horizontal distance from the top of the continuous strength member to the centerline of the ship, in m;

B_1 — breadth of ship at section considered, in m.

In calculation, Z_c and y are to be measured to the point giving the maximum value of Z_t.

2.2.4.5 Where deck longitudinals or deck girders are arranged above the strength deck, the sectional area may be included in the calculation of the hull girder section modulus. The lever Z_t is to be taken as the vertical distance from the neutral axis to the moulded deck line at side amidships plus the depth of the longitudinal member.

2.2.4.6 Deck openings having a length in the fore-and-aft direction exceeding 2.5 m or a breadth exceeding 1.2 m or 0.04B (whichever is the lesser) or scallops where scallop-welding is applied

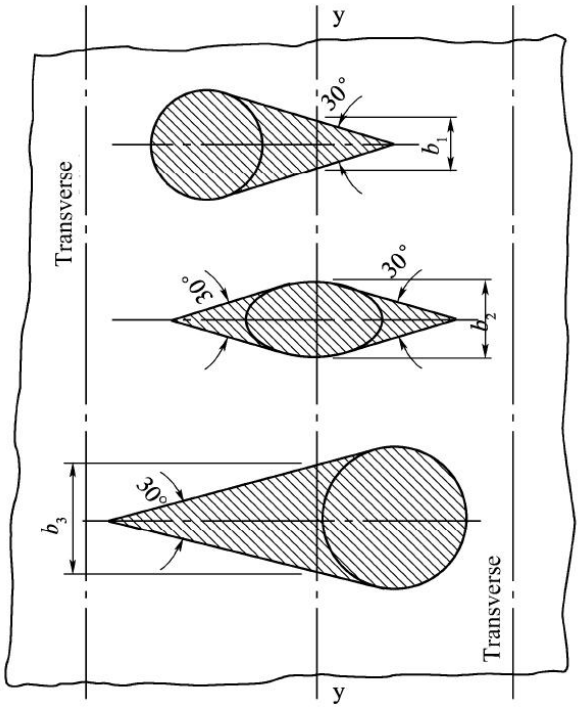
are to be deducted from the sectional areas used in the calculation of the hull girder section modulus.

2.2.4.7 Smaller openings (including manholes, lightening holes, single scallops in way of seams, etc.) smaller than those stated in 2.2.4.6 above need not be deducted from the sectional areas used in the calculation of the hull girder section modulus, provided that the sum b_c of their breadths or shadow area breadths (The shadow area will be obtained by drawing two tangent lines with an opening angle of 30°, as shown in Figure 2.2.4.7) in one transverse section complies with the following or that the section modulus at deck or bottom is not reduced by more than 3%:

$$b_c \le 0.06\left(B_1 - \sum b\right)$$

where: B_1 — breadth of ship at section considered, in m;

Σb — sum of breadths of deductible openings at section considered in accordance with 2.2.4.6 of this Section, in m.



Sum of breadths of small openings at *y-y* section is to be $b_c = b_1 + b_2 + b_3$

Figure 2.2.4.7

2.2.4.8 Openings in longitudinals or longitudinal girders (such as lightening holes, freeing ports, single scallops in way of welds) need not be deducted from the sectional areas used in the calculation of the hull girder section modulus, if their depth does not exceed 25% of the web depth (with a maximum depth of 75 mm for scallops).

2.2.5 Hull girder bending strength

2.2.5.1 The minimum midship section modulus① W_0 at deck and keel is not to be less than that obtained from the following formula:

$$W_0 = CL^2B(C_b + 0.7)K \quad \text{cm}^3$$

where: C — coefficient②, to be taken in accordance with 2.2.3.1 of this Section;

C_b — the same as that in 2.2.3.1 of this Section;

L — length of ship, in m;

B — breadth of ship, in m;

K — material factor.

Scantlings of all continuous longitudinal members of the hull girder based on the minimum midship section modulus W_o are to be maintained within 0.4L amidships. However, in special cases, based on consideration of type of ship, hull form and loading conditions, the scantlings may be gradually reduced towards the ends of the 0.4L amidships, bearing in mind the desire not to inhibit the vessel's loading flexibility. In ships where part of the longitudinal strength material in the deck or bottom area are forming boundaries of tanks for oil cargoes or ballast water and such tanks are provided with an effective corrosion protection system, certain reductions in the scantlings of these boundaries are allowed. These reductions, however, are in no case to reduce the minimum hull girder section modulus for a new ship by more than 5%.

2.2.5.2 The moment of inertia of midship section about the horizontal neutral axis I is not to be less than that obtained from the following formula:

$$I = 3W_0L / K \quad \text{cm}^4$$

where: W_0 — the minimum midship section modulus, in cm³, calculated in accordance with 2.2.5.1 of this Section;

L — length of ship, in m;

K — material factor.

2.2.5.3 The hull girder bending strength outside 0.4L amidships is to comply with the requirements of 2.2.5.4 of this Section and also the following requirements:

(1) As a minimum, hull girder bending strength checks are to be carried out at the following locations:

— in way of the forward end of the engine room;

— in way of the forward end of the foremost cargo hold;

— at any locations where there are significant changes in hull cross-section;

— at any locations where there are changes in the framing system.

(2) Buckling strength of members contributing to the longitudinal strength and subjected to compressive and shear stresses is to be checked, in particular in regions where changes in the framing system or significant changes in the hull cross-section occur.

(3) Continuity of structure is to be maintained throughout the length of the ship. Where significant changes in structural arrangement occur, adequate transitional structure is to be provided.

(4) For ships with large deck openings such as container ships, sections at or near to the aft and forward quarter length positions are to be checked. For such ships with cargo holds aft of the

---

① The minimum midship section modulus applies to ships in unrestricted service. However, it may not be applicable to ships of unusual type or design, e.g. for ships of unusual main proportions and/or weight distributions, and special consideration is to be given.

② For ships in service, C is 0.9 times the value calculated in 2.2.3.1.

superstructure, deckhouse or engine room, strength checks of sections in way of the aft end of the aft-most holds, and the aft end of the deckhouse or engine room are to be performed.

2.2.5.4 The designer is to provide permissible hogging and sagging still water bending moments $\overline{M}_s$ (+) and $\overline{M}_s$ (−) of hull girders at each transverse section along the ship's length, provided that the following conditions are satisfied:

(1) The permissible hogging and sagging still water bending moments $\overline{M}_s$ of hull girders are to cover the most severe hogging and sagging design still water bending moments calculated for any navigation condition given in the loading manual, see 2.2.2 of this Section.

(2) The permissible hogging and sagging still water bending moments $\overline{M}_s$ of hull girders are not to be greater than the values obtained from the following formulae:

$$\overline{M}_s(+)_{max} = \overline{M} - M_W(+) \quad \text{kN·m}$$

$$\overline{M}_s(-)_{min} = -\overline{M} - M_W(-) \quad \text{kN·m}$$

where: M_W — wave bending moment, see 2.2.3.1 of this Section;

$\overline{M}$ — combined permissible bending moment, in kN · m, to be taken as one of the values obtained from the following formulae, whichever is the lesser:

$$\overline{M} = F_d W_d [\sigma] \times 10^{-3} \quad \text{kN·m}$$

$$\overline{M} = F_b W_b [\sigma] \times 10^{-3} \quad \text{kN·m}$$

where: F_d, F_b — determined in accordance with 2.2.5.6(1);

W_d — section modulus at deck, in cm^3;

W_b — section modulus at keel, in cm^3;

Permissible bending stress of hull girder $[\sigma]$① is determined in accordance with the following requirements:

$[\sigma] = 175/K$, in N/mm^2, for 0.4 L amidships;

$[\sigma] = 125/K$, in N/mm^2, for 0.1 L from the ship's ends;

for other areas, to be obtained by linear interpolation, where K is material factor.

2.2.5.5 Longitudinal bending stress is to be calculated in accordance with the following formula:

$$\sigma = \frac{\left|\overline{M}_s + M_W\right|}{W_c} \times 10^3 \quad \text{N/mm}^2$$

where: $\overline{M}_s$ — permissible still water bending moment, in kN·m, see 2.2.5.4 of this Section;

M_W — wave bending moment, in kN·m, calculated in accordance with 2.2.3.1 of this Section;

W_c — hull girder section modulus at the point considered, in cm^3.

2.2.5.6 The reduction factor of scantlings of local members is to comply with the following:

(1) Where the maximum longitudinal bending stresses at deck and keel are less than the permissible bending stress [σ], appropriate reduction factors F_d and F_b may be taken to reduce the scantlings of local member provided the following conditions are met:

① Permissible bending stress of hull girder outside 0.4L amidships is generally in accordance with this paragraph.

$$F_d \geq \frac{\sigma_d}{[\sigma]}$$

$$F_b \geq \frac{\sigma_b}{[\sigma]}$$

where: σ_d — longitudinal bending stress at deck, in N/mm^2;

σ_b — longitudinal bending stress at keel, in N/mm^2;

$[\sigma]$ — permissible bending stress, see 2.2.5.4(2) of this Section.

In calculation of the thickness of shell plating t_1 and deck t_1, reduction factor F_d may be calculated based on sagging bending moment and F_b may be calculated based on the hogging bending moment.

For shell plating and deck, reduction factors F_d and F_b are not to be less than 0.67; for framing, reduction factors F_d and F_b are not to be less than 0.75.

(2) For ships less than 65 m in length, 1 is to be taken for both F_d and F_b.

(3) For containerships of 90 m in length and over, see Section 2 of Chapter 7 for the longitudinal bending stress and permissible bending stress in calculation of F_d and F_b.

2.2.5.7 Where higher tensile steel is used in some portions of hull, the vertical extent of application of the higher tensile steel is not to be less than:

Where higher tensile steel is applied to the strength deck, the region y_1 $(1 - K/F_d)$ below the deck line is to be made of higher tensile steel; where applied to the bottom, the region y_2 $(1 - K/F_b)$ above the keel is to be made of higher tensile steel. y_1 and y_2 are the vertical distances from the neutral axis to the deck line at side and to the plate keel respectively, in m, as shown in Figure 2.2.5.7. K is material factor, F_d and F_b are as defined in 2.2.5.6 above.

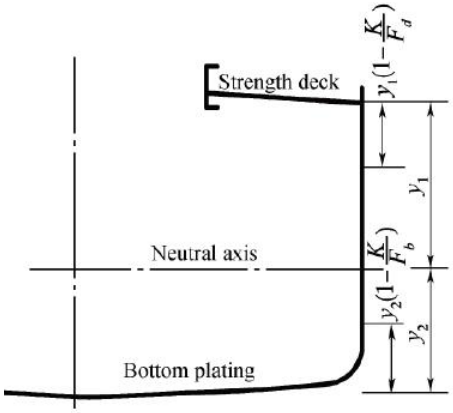


Figure 2.2.5.7

2.2.5.8 Where higher tensile steel is used amidships and low carbon steel at the ends of the ship, the region in which higher tensile steel is used is to be extended to the points where the thickness required for low carbon steel is equal to that of the higher tensile steel (see Figure 2.2.5.8).

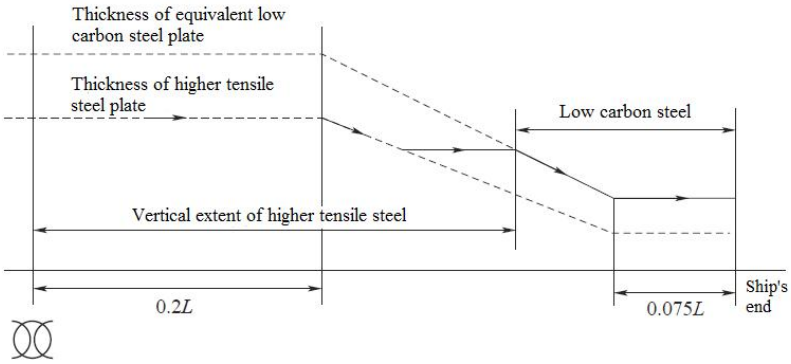

Figure 2.2.5.8

2.2.5.9 Where higher tensile steel is applied to strength deck structure, corresponding higher tensile steel is usually to be applied to the continuous members (e.g. stiffening members of hatch coamings and deck openings) welded to strength deck.

2.2.6 Hull girder shearing strength

2.2.6.1 Design still water shear force

(1) Under different loading conditions, the design still water shear force at each transverse section along the ship's length is to meet the following conditions:

$$F_s(+) \le \overline{F_s}(+)$$

$$\left| F_s(-) \right| \le \left| \overline{F_s}(-) \right|$$

where: F_s — design still water shear force under the conditions considered, in kN;

$\overline{F_s}$ — permissible still water shear force, in kN, calculated in accordance with 2.2.6.2.

(2) For type 1 and type 2 hull sections as shown in Table 2.2.6.2, the still water shear force F_s at transverse bulkhead is to be corrected in respect to alternate or significantly non-homogeneous hold loading conditions. The correction of shear force is as shown in Figure 2.2.6.1. The values N_k and N_m of shear force correction are to be calculated in accordance with the following formulae respectively:

$$N_k = F\,|F_{sA} - F_{sB}| \quad \text{kN}$$

$$N_m = F|F_{sA} - F_{sC}| \quad \text{kN}$$

where: F_{sA}, F_{sB}, F_{sC} — shear force in kN, obtained by calculation based on hull girder at transverse bulkheads A, B and C respectively;

F — correction factor of still water shear force, calculated in accordance with the following formula:

$$F = \frac{B_0}{2.2(B + l_H)}$$

where: B_0 — average breadth of the flat part of inner bottom of the hold considered, in m;

B — breadth of ship, in m;

l_H — length of hold, in m.

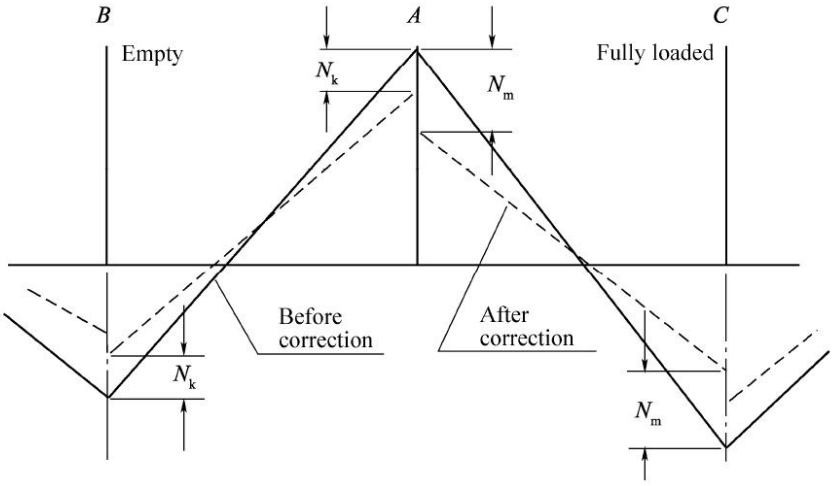

Figure 2.2.6.1

2.2.6.2 The designer is to provide permissible still water shear forces $\overline{F}_s$ (+) and $\overline{F}_s$ (−) of hull girders at each transverse section along the ship's length, provided that the following conditions are satisfied:

(1) The positive and negative permissible still water shear forces $\overline{F}_s$ of hull girders are to cover the most severe positive and negative design still water shear forces calculated for any navigation condition given in the loading manual, see 2.2.2 of this Section.

(2) The positive and negative permissible still water shear forces $\overline{F}_s$ of hull girders are not to be greater than the values obtained from the following formulae:

$$\overline{F_s}\,(+)_{\max}=[\tau]\frac{I\delta}{S}\times 10^{-2}-F_w(+) \quad \text{kN}$$

$$\overline{F_s}\,(-)_{\min}=-[\tau]\frac{I\delta}{S}\times 10^{-2}-F_w(-) \quad \text{kN}$$

where: F_w — wave shear force, in kN, calculated in accordance with 2.2.3.2;

I — moment of inertia about the horizontal neutral axis at the transverse section under consideration, in cm^4;

S — static moment, in cm^3, about the horizontal neutral axis, of the area of the effective longitudinal members above the horizontal neutral axis, taken at the transverse section under consideration;

Permissible shearing stress $[\tau] = 110/K$, in N/mm^2, where K is material factor;

δ — the lesser of δ_1 and δ_2, calculated in accordance with the following formulae:

$$\delta_1=\frac{t_1}{f_1+m_1}$$

$$\delta_2=\frac{t_2}{f_2+m_2}$$

t_1 — thickness (the total thickness of inner and outer plating for double hull-skin ship) of side shell at the horizontal neutral axis of the section under consideration, in mm;

t_2 — thickness of longitudinal bulkhead plating at the horizontal neutral axis of the section under consideration, in mm;

f_1, f_2, m_1, and m_2 — factors, see Table 2.2.6.2.

Factors f_1, f_2, m_1 and m_2 **Table 2.2.6.2**

No.	Hull configuration	Factor f_i	Factor m_i
1		$f_1 = 0.5$	$m_1 = 0$
2		$f_1 = 0.5$	$m_1 = 0$
3		$f_1 = 0.261 + 0.058\, A_1 / A_2$ $f_2 = 0.478 - 0.116\, A_1 / A_2$	$m_1 = 0.5\, m_2$ $m_2 = 0.5(0.1 + \gamma)$
4		$f_1 = 0.154 + 0.08\, A_1 / A_2$ $f_2 = 0.346 - 0.08\, A_1 / A_2$	$m_1 = m_2$ $m_2 = (0.1 + \gamma)\ \frac{b}{B}$

Notes: A_1, A_2— shear areas of side shell and longitudinal bulkhead plating respectively, in cm^2, at one side of the section under consideration. The area for the centreline bulkhead is actual area and not to be reduced for symmetry around the centreline;

b — horizontal distance from longitudinal bulkhead to side shell plating, in m;

B — breadth of ship, in m;

γ — for transversely non-homogeneous loading condition, γ = 0.15; for transversely homogeneous loading condition, γ = 0.

2.2.6.3 For hull configurations not included in Table 2.2.6.2, e.g. ships with three or four longitudinal bulkheads, the shearing stresses at side shell and longitudinal bulkhead plating may be determined by direct calculation.

2.2.6.4 Shearing stress①

(1) The shearing stress τ at side shell is to be calculated in accordance with the following formula:

$$\tau = \frac{\left|\overline{F_s} + F_w\right| S}{I\delta_1} \times 10^2 \quad \text{N/mm}^2$$

where: $\overline{F_s}$ — permissible still water shear force, in kN, see 2.2.6.2 of this Section;

S — static moment, in cm^3. Where the point considered is above the horizontal neutral axis, S is to be taken as the static moment, about the horizontal neutral axis, of the area of all longitudinal members passing through the point above the neutral axis. Where the point considered is below the horizontal neutral axis, S is to be taken as the static moment, about the horizontal neutral axis, of the area of all longitudinal members passing through the point below the neutral axis;

F_w, I and δ_1 — see 2.2.6.2 of this Section.

① Direct shearing stress calculation may be used, subject to approval by CCS.

(2) Shearing force τ at longitudinal bulkhead plating is to be calculated in accordance with the following formula:

$$\tau = \frac{\left|\overline{F}_s + F_w\right| S}{I\delta_2} \times 10^2 \quad \text{N/mm}^2$$

where: $\overline{F}_s$, S — see 2.2.6.4 (1) of this Section;

F_w, I and δ_2 — see 2.2.6.2 of this Section.

2.2.7 Buckling strength

2.2.7.1 For ships of 90 m and over in length, where the plate panels and longitudinals are subject to hull girder bending and shear stresses, the buckling strength is to be checked according to the following requirements.

2.2.7.2 The working stress σ in compression of the plate panels and longitudinals as calculated in 2.2.5.5 of this Section (taken not less than 30/K, in N/mm^2, where K is material factor) is to comply with the following formula:

$$\sigma \le \frac{1}{\beta}\sigma_c$$

where: β = 1, for plating and for web plating of stiffeners (local buckling);

β = 1.1, for stiffeners;

σ_c — critical buckling stress in compression, calculated according to 2.2.7.6 of this Section.

2.2.7.3 The working shear stress τ of plate panels as calculated in 2.2.6.4 of this Section is to comply with the following formula:

$$\tau \le \tau_c$$

where: τ_c — critical buckling stress in shear, calculated according to 2.2.7.7 of this Section.

2.2.7.4 The ideal elastic buckling stresses of the plates are to be obtained from the following formulae:

(1) The ideal elastic buckling stress σ_E of the compression plate panel is to be obtained from the following formula:

$$\sigma_E = 0.9\, K_c E \left(\frac{t_b}{1000s}\right)^2 \quad \text{N/mm}^2$$

where: E — modulus of elasticity of material, in N/mm^2;

s — shorter side of plate panel, in m;

t_b — net thickness, in mm, of plating, considering standard deductions equal to the values given in Table 2.2.7.4;

Standard Deduction of Thickness **Table 2.2.7.4**

Structure	Standard deduction (mm)	Limit values min-max (mm)
Compartments carrying dry bulk cargoes: One side exposure to ballast or liquid cargo, vertical surfaces and surfaces sloped at an angle greater than 25º to the horizontal line.	0.05 t	0.5 ~ 1
One side exposure to ballast or liquid cargo, horizontal surfaces and surfaces sloped at an angle less than 25º to the horizontal line;	0.10 t	2 ~ 3

Two side exposure to ballast or liquid cargo, vertical surfaces and surfaces sloped at an angle greater than 25º to the horizontal line.		
Two side exposure to ballast or liquid cargo, horizontal surfaces and surfaces sloped at an angle less than 25º to the horizontal line.	0.15 t	2 ~ 4

Note: t is the designed thickness of plating, in mm.

K_c – coefficient, calculated according to the following:

$K_c = \dfrac{8.4}{\psi + 1.1}$ for plating with longitudinal stiffeners (parallel to compressive stress);

$K_c = C\left[1+\left(\dfrac{S}{l}\right)^2\right]^2 \dfrac{2.1}{\psi + 1.1}$ for plating with transverse stiffeners (perpendicular to compressive stress);

where:

l — longer side of plate panel, in m;

C = 1.3 when plating stiffened by floors or deep girders;

C = 1.21 when stiffeners are angles or T-sections;

C = 1.10 when stiffeners are bulb flats;

C = 1.05 when stiffeners are flat bars;

ψ — ratio between smallest and largest compressive stress, $0 \le \psi \le 1$ (see Figure 2.2.7.4).

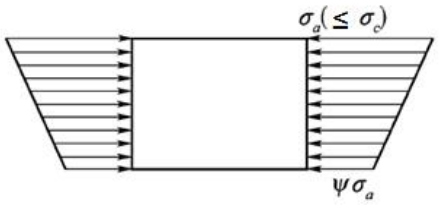

Figure 2.2.7.4

(2) The ideal elastic buckling stress τ_E in shear of plate panels subjected to shearing forces is to be obtained from the following formula:

$$\tau_E = 0.9K_t E\left(\frac{t_b}{1000s}\right)^2 \quad \text{N/mm}^2$$

where: $K_t = 5.34 + 4\left(\dfrac{s}{l}\right)^2$;

for E, t_b, s and l, see (1) above.

2.2.7.5 The ideal elastic buckling stresses of longitudinals are to be obtained from the following formulae:

(1) For the column buckling mode (perpendicular to plane of plating) without rotation of the cross section, the ideal elastic buckling stress σ_E of longitudinals is to be obtained from the following formula:

$$\sigma_E = 0.001E\frac{I_a}{Al^2} \quad \text{N/mm}^2$$

where: I_a — moment of inertia, in cm^4, of longitudinal, including plate flange and calculated with thickness as specified in Table 2.2.7.4 of this Section;

A — cross-sectional area, in cm^2, of longitudinal, including plate flange and calculated with thickness as specified in Table 2.2.7.4 of this Section;

l — span, in m, of longitudinal.

(2) The ideal elastic buckling stress σ_E of longitudinals for the torsional buckling mode is to be obtained from the following formula:

$$\sigma_E = \frac{\pi^2 EI_W}{I_p l^2 \times 10^4}\left(n^2 + \frac{K_B}{n^2}\right) + 0.385\,E\,\frac{I_t}{I_p} \quad \text{N/mm}^2$$

where: $K_B = \frac{Cl^4}{\pi^4 EI_W}\times 10^6$;

n — number of half waves, given by Table 2.2.7.5:

Number of Half Waves **Table 2.2.7.5**

	$0 < K_B \le 4$	$4 < K_B \le 36$	$36 < K_B \le 144$	$(n-1)^2\,n^2 < K_B \le n^2\,(n+1)^2$
n	1	2	3	n

I_t — St Venant's moment of inertia, in cm^4, of profile (without plate flange), to be obtained by the following formula:

$I_t = \frac{h_w t_w^3}{3} \times 10^{-4}$, for flat bars;

$I_t = \frac{1}{3}\left[h_w t^3{}_w + b_f t^3{}_f\left(1 - 0.63\frac{t_f}{b_f}\right)\right]\times 10^{-4}$ for flanged profiles;

I_p — polar moment of inertia, in cm^4, of profile about connection of stiffener to plate:

$I_p = \frac{h^3{}_w t_w}{3} \times 10^{-4}$ for flat bars;

$I_p = (\frac{h^3{}_w t_w}{3} + h_w^2 b_f t_f)\times 10^{-4}$ for flanged profiles;

I_w — sectional moment of inertia, in cm^6, of profile about connection of stiffener to plate:

$I_w = \frac{h^3{}_w t^3{}_w}{36} \times 10^{-6}$ for flat bars;

$I_w = \frac{t_f b_f^3 h_w^2}{12} \times 10^{-6}$ for Tee profiles;

$I_w = \frac{b_f^3 h_w^2}{12\left(b_f + h_w\right)^2}\left[t_f\left(b_f^2 + 2b_f h_w + 4h_w^2\right) + 3t_w b_f h_w\right] \times 10^{-6}$ for angles and bulb profiles;

l — span of longitudinal, in m;

E — modulus of elasticity of material, in N / mm^2;

where: h_w — web height, in mm;

t_w — web thickness, in mm, considering standard deductions as specified in Table 2.2.7.4 of this Section;

b_f — flange width, in mm;

t_f — flange thickness, in mm, considering standard deductions as specified in Table 2.2.7.4 of this Section. For bulb profiles the mean thickness of the bulb may be used;

C — spring stiffness exerted by supporting plate panel, obtained by the following formula:

$$C = \frac{K_p E t_p^3}{3s\left(1 + \frac{1.33 K_p h_w t_p^3}{1000 s t_w^3}\right)} \times 10^{-3}$$

s — spacing of profiles, in m;

t_p — panel thickness, in mm, considering standard deductions as specified in Table 2.2.7.4 of this Section;

$K_p = 1 - \eta_P$, not to be taken less than zero. For flanged profiles, K_p need not be taken less than 0.1;

$$\eta_p = \frac{\sigma}{\sigma_{EP}};$$

σ — working pressure in compression, calculated in accordance with 2.2.5.5 of this Section, but not to be taken as less than $30/K$, in N/mm², where K is material factor;

σ_{EP} — elastic buckling stress of supporting plate as calculated in 2.2.7.4 of this Section.

(3) Web and flange buckling of longitudinals

① For web plate of longitudinals, the ideal elastic buckling stress σ_E is to be obtained from the following formula:

$$\sigma_E = 3.8E\left(\frac{t_w}{h_w}\right)^2 \quad \text{N/mm}^2$$

where: t_w, h_w, E — see (2).

② For flanges on angles and T-sections of longitudinals, buckling is taken care of by the following requirement:

$$\frac{b_f}{t_f} \le 15$$

where: b_f — flange width, in mm, for angles, half the flange width for T-sections;

t_f — flange thickness, in mm.

2.2.7.6 The critical buckling stress in compression σ_c is determined as follows:

$$\sigma_c = \sigma_E \qquad \text{for } \sigma_E \le \frac{R_{eH}}{2}$$

$$\sigma_c = R_{eH}\left(1 - \frac{R_{eH}}{4\sigma_E}\right) \qquad \text{for } \sigma_E > \frac{R_{eH}}{2}$$

where: R_{eH} — yield stress of material, in N/mm²;

σ_E — ideal elastic buckling stress, in N/mm², calculated according to 2.2.7.4(1) and 2.2.7.5 of this Section.

2.2.7.7 The critical buckling stress in shear τ_c is determined as follows:

$$\tau_c = \tau_E \qquad \text{for } \tau_E \le \frac{\tau_s}{2}$$

$$\tau_c = \tau_s\left(1 - \frac{\tau_s}{4\tau_E}\right) \qquad \text{for } \tau_E > \frac{\tau_s}{2}$$

where: $\tau_s = \frac{R_{eH}}{\sqrt{3}}$;

R_{eH} — yield stress of material, in N/mm^2;

τ_E — ideal elastic buckling stress in shear, in N/mm^2, calculated according to 2.2.7.4(2) of this Section.

2.2.8 Loading manual and loading instrument

2.2.8.1 On completion of construction of the ship, a Loading Manual is to be formulated in time and submitted by the designer to CCS for approval. CCS Guidelines for Preparation of Loading Manuals may be referred to for formulating the Loading Manual.

2.2.8.2 The ship is to be loaded in accordance with the requirements specified in the Loading Manual to avoid the creation of unacceptable stresses in the hull structures.

2.2.8.3 The Loading Manual is to contain the following:

(1) The loading conditions on which the design of the ship has been based, including curves of permissible still water bending moment and shear force along the length of the ship.

(2) The results of the calculations of still water bending moments and shear forces under various loading conditions and where necessary, limitations due to torsional and lateral loads.

(3) The allowable local loading for local structures (such as hatch covers, decks and double bottom, etc.).

2.2.8.4 Loading instruments are to comply with the following specifications:

(1) A loading instrument is either an analog or a digital instrument, by means of which it can be easily and quickly ascertained that the still water bending moment, shear forces and where applicable, the still water torsional moments and lateral loads at specified read-out points will not exceed the specified permissible values in any loading or ballasting condition.

(2) The loading instrument is generally to be provided with an operation manual.

(3) Single-point loading instruments are not acceptable.

(4) The detailed requirements for loading instruments are referred to Appendix 1 of this Chapter.

2.2.8.5 Those ships complying with one of the following provisions are Category I ships:

(1) Ships with large deck openings where combined stresses due to vertical and horizontal hull girder bending as well as torsional and lateral loads are to be considered.

(2) Ships possibly with non-homogeneous loadings, where the cargo and/or ballast may be unevenly distributed. Ships less than 120 m in length, when uneven distribution of cargo and/or ballast is considered in design, belong to Category II.

(3) Chemical tankers and gas carriers.

2.2.8.6 Those ships complying with one of the following provisions are Category II ships:

(1) ships with such arrangements that would allow only a small possibility for variation in the distribution of cargo and ballast, and ships operating on a regular and fixed tradeing pattern where the loading manual gives sufficient guidance;

(2) ships for which an exception is given under Category I.

2.2.8.7 A loading manual approved by CCS is to be supplied to all ships except those of Category II with length less than 90 m of which the deadweight does not exceed 30% of the displacement at the summer load line draft.

2.2.8.8 An approved loading manual is to be supplied to all ships of Category I with 100 m or over in length.

2.2.8.9 Bulk carriers, ore carriers and combination carriers of 150 m or over in length are to be provided with a loading manual and a loading instrument in accordance with the requirements of Section 7, Chapter 8 of this PART.

2.2.8.10 Conditions for approval of loading manuals:

(1) The approval of the loading manual is to be based on the final data of the ship. The manual is to include the design loading and ballasting conditions upon which the approved scantlings of hull structures are approved.

(2) In case of modifications resulting in changes to the main data of the ship, a new approved loading manual is to be issued.

(3) The loading manual must be prepared in a language understood by the users. If this language is not English, a translation into English is to be included.

2.2.8.11 Conditions for approval of loading instruments:

(1) The following are to be included in loading instruments and approved:

① Confirmation of type approval, if any;

② Confirming that the final data of the ship have been used;

③ Confirmation of the number and positions of read-out points;

④ Confirmation of relevant limits for all read-out points;

⑤ Checking of proper installation and operation of the instrument on board, in accordance with the approved test report of loading calculation, and that a copy of the operation manual is available.

(2) In case of modifications implying changes in the main data of the ship, the loading instrument is to be modified accordingly and reapproved.

(3) The operation manual and the instrument output must be prepared in a language understood by the users. If this language is not English, a translation into English is to be included.

(4) The operation of the loading instruments is to be verified upon installation. It is to be checked that the operation manual and the approved test loading conditions are available on board.

2.2.9 Direct calculation of wave loads

2.2.9.1 The direct calculation of wave loads is to be based on the following assumptions:

(1) The calculation software is to be based on the three-dimensional linear or non-linear wave theory and approved by the classification society.

(2) Wave statistics based on the marine environment of the North Atlantic, as given in IACS REC34, are used in the prediction of wave loads.

(3) The requirements for wave frequencies, wave heading angles and the considered ship speed are given in Section 5, Chapter 1 of this PART.

(4) The wave spectrum and energy spread function under consideration are given in Section 5, Chapter 1 of this PART.

(5) The long-term prediction results at the probability level of 10^{-8} are taken as calculation results.

2.2.9.2 The hydrodynamic models used in calculation are to comply with the following requirements:

(1) The mass model is to correctly reflect the mass and its distribution of the real ship, ensuring that the error between mass of the model and that of the real ship is not greater than 0.1% and that the error between position of center of gravity of the model and that of the real ship is not greater than 0.1%L.

(2) The model of wetted surface is to be sufficiently refined for an accurate simulation of the shape of the real ship from the hydrodynamic perspective. The error between displacement of the model and that of the real ship is not to be greater than 0.1%, the error between position of center of buoyancy of the model and that of the real ship is not to be greater than 0.1% L, and the number of elements is generally not to be less than 2,000.

2.2.9.3 The wave bending moments and shear forces obtained by the linear wave theory are to be subject to non-linear correction as follows:

(1) The hogging wave bending moment M_W (+) and the sagging wave bending moment M_W (–) are to be calculated by the following formulas:

$$M_W(+)=Mf_{nl\text{-}h}M_{W,cal} \quad \text{kN·m}$$

$$M_W(-)=-Mf_{nl\text{-}s}M_{W,cal} \quad \text{kN·m}$$

where: $M_{W,\,cal}$ — maximum vertical wave bending moment between 0.4L and 0.6L, obtained by direct calculation based on linear wave theory;

M — distribution factor of bending moment along ship's length, see Figure 2.2.3.1 of this Chapter;

f_{nl-h} , f_{nl-s} — non-linear correction factor, determined by the following formulas:

$$f_{nl-h}=\frac{190C_b}{95C_b+55(C_b+0.7)}$$

$$f_{nl\text{-}s}=\frac{110(C_b+0.7)}{95C_b+55(C_b+0.7)}$$

where: C_b — block coefficient, taken not less than 0.6.

(2) The hogging wave shear force F_W (+) and the sagging wave shear force F_W (−) are to be calculated by the following formulas:

$$F_W(+)=F_{nl,1}F_{WV,\,\max}\text{kN}$$

$$F_W(-)=-F_{nl,2}F_{WV,\,\max}\text{kN}$$

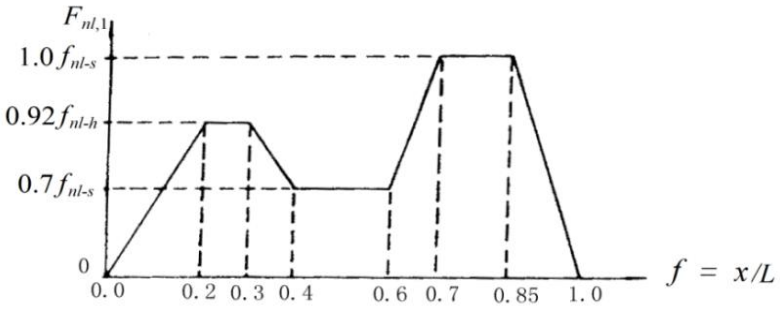
where: $F_{nl,1}$, $F_{nl,2}$ — distribution factors taking non-linear correction into account, see Figures 2.2.9.3(1) and 2.2.9.3(2) respectively. For f_{nl-h}, f_{nl-s} in the Figures, see (1) above.

$F_{WV,\,\max}$ is to be calculated by the following formula:

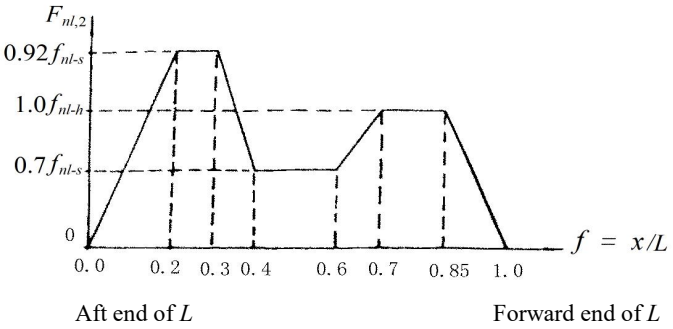
$$F_{WV,\max}=\max\left(\frac{\max\left|F_{WV,CAL,A}\right|}{0.92},\frac{\max\left|F_{WV,CAL,F}\right|}{1.0}\right)\text{kN}$$

where: $F_{WV,\,CAL,\,A}$ — wave shear force, in kN, directly calculated for sections with $x/L < 0.5$;

$F_{WV,\,CAL,\,F}$ — wave shear force, in kN, directly calculated for sections with $x/L \geq 0.5$.



Figures 2.2.9.3(1) Distribution of Factor $F_{nl,1}$ along Ship's Length



Figures 2.2.9.3(2) Distribution of Factor $F_{nl,2}$ along Ship's Length

2.2.9.4 For specific ships, e.g. engineering ships which need to carry out short-term operation, short-term prediction of wave loads is to be used to determine wave loads in the operating condition based on the most severe short-term sea state provided by the designer. The period of short-term prediction is generally taken as 3 hours or the operating hours provided by the designer, whichever is greater.

Section 3 SHELL PLATING

2.3.1 Bottom shell

2.3.1.1 Bottom shell means the shell plating between the plate keel and the bilge strake.

2.3.1.2 In a ship with transverse bottom framing, the thickness t of bottom shell plating within 0.4L amidships is not to be less than the following:

$$t_1 = 0.072sE^{-1}(L+170)\sqrt{\frac{F_b}{K}} \quad \text{mm}$$

$$t_2 = 7.0s\sqrt{(d+h_1)F_bK} \quad \text{mm}$$

where: s — spacing of frames, in m, to be taken as not less than the standard spacing of frames;

d — draught, in m;

L — length of ship, in m, to be taken as not greater than 200 m;

F_b — reduction factor, see 2.2.5.6 of this Chapter;

$E = 1+\frac{s^2}{S^2}$, where S is spacing of girders or keelsons, in m;

h_1 = 0.26 C, to be taken as not greater than 0.2 d;

C — coefficient, see 2.2.3.1 of this Chapter;

K — material factor.

2.3.1.3 In a ship with longitudinal bottom framing, the thickness t of bottom shell plating within 0.4L amidships is not to be less than the values obtained from the following:

$$t_1 = 0.043s(L+230)\sqrt{\frac{F_b}{K}} \quad \text{mm}$$

$$t_2 = 5.6s\sqrt{(d+h_1)F_bK} \quad \text{mm}$$

where: s — spacing of longitudinals, in m, to be taken as not less than the standard spacing of longitudinals;

d — draught, in m;

L — length of ship, in m, to be taken as not greater than 190 m;

F_b, h_1 — see 2.3.1.2 of this Section;

K — material factor.

2.3.1.4 The thickness t of bottom shell plating within the regions of 0.075L from the ship's ends is not to be less than that obtained from the following formula:

$$t = (0.035L + 6)\sqrt{\frac{sK}{0.7}} \quad \text{mm}$$

where: L — length of ship, in m, L need not be taken as greater than 300 m;

s — spacing of frames or longitudinals, in m, to be taken as not less than 0.7;

K — material factor.

2.3.1.5 The thickness of bottom shell plating is not to be less than that obtained by the following formula:

$$t = (0.035L + 6)\sqrt{K} \quad \text{mm}$$

where: L — length of ship, in m;

K — material factor.

The thickness of bottom shell plating beyond 0.4L amidships is to be tapered gradually to the end thickness of bottom shell plating.

2.3.1.6 The thickness of bottom shell plating at fore end is, in addition, to comply with the relevant requirements of Section 15 of this Chapter.

2.3.2 Plate keel

2.3.2.1 The width b of the plate keel is not to be less than that obtained from the following formula:

$$b = 900 + 3.5L \quad \text{mm}$$

where: L — length of ship, in m.

The width of the plate keel need not be greater than 1,800 mm, and is to be maintained over the whole length of the ship.

2.3.2.2 The thickness of the plate keel is not to be less than that of the bottom shell plating calculated according to 2.3.1 of this Section in accordance with its structural configuration plus 2.0 mm nor less than that of the adjacent bottom shell plating.

2.3.3 Bilge strake

2.3.3.1 Where the bilge is framed transversely, the thickness of the bilge plating is not to be less than the value obtained from 2.3.1.2 of this Section, and where the bilge is framed longitudinally, the thickness of the bilge plating is not to be less than the value obtained from 2.3.1.3 of this Section.

2.3.3.2 Where both the bottom and side shells are framed longitudinally and the bilge longitudinals are omitted, and where transverse strength members or corresponding bilge brackets are fitted in accordance with the requirements of 2.6.15.5 of this Chapter, the thickness of the bilge strake is neither to be less than $\frac{rF_b}{165K}$ (r being the radius of bilge, in mm, K being material factor and F_b being reduction factor of bottom), nor to be less than that of the adjacent bottom plating.

2.3.4 Side shell plating

2.3.4.1 Side shell plating means the shell plating between the bilge strake and the sheer strake.

2.3.4.2 Where the side shell is framed transversely, the thickness t of side shell plating within $0.4L$ amidships is to be as follows:

(1) The thickness t of side shell plating above $\frac{3}{4}D$ from base is not to be less than the following:

$$t_1 = 0.073sE^{-1}(L+110)\sqrt{\frac{F_d}{K}} \quad \text{mm}$$

$$t_2 = 4.2s\sqrt{(d+h_2)K} \quad \text{mm}$$

(2) The thickness t of side shell plating within $\frac{1}{2}D$, the centre point of which is $0.5D$ from base, is not to be less than the following:

$$t_1 = 0.06s(L+110)\sqrt{\frac{F_m}{K}} \quad \text{mm}$$

$$t_2 = 5.1s\sqrt{(d+h_2)K} \quad \text{mm}$$

(3) The thickness t of side shell plating below $\frac{1}{4}D$ from base is not to be less than the following:

$$t_1 = 0.072sE^{-1}(L+110)\sqrt{\frac{F_b}{K}} \quad \text{mm}$$

$$t_2 = 6.3s\sqrt{(d+h_1)F_bK} \quad \text{mm}$$

where: s — spacing of frames, in m; to be taken as not less than the standard spacing of frames;

L — length of ship, in m, L need not be taken as greater than 190 m;

d — draught, in m;

F_d, F_b — reduction factors, see 2.2.5.6 of this Chapter;

F_m — reduction factors, to be taken as F_d or F_b, whichever is the greater;

$E = 1+\frac{s^2}{S^2}$, where S is the spacing of side stringers, in m;

$h_2 = 0.5C$, to be taken as not greater than $0.36d$;

h_1, C — see 2.3.1.2 of this Section;

K — material factor.

(4) In calculation of t_1, except the minimum range of high tensile steel stipulated in Section 2 of this Chapter, the material factor K may be taken as 1.

2.3.4.3 Where the side shell is framed longitudinally, the thickness t of side shell plating within 0.4L amidships is to be as follows:

(1) The thickness t of side shell plating above $\frac{1}{2}D$ from base is not to be less than the following:

$$t_1 = 0.06s(L+110)\sqrt{F_d / K} \quad \text{mm}$$

$$t_2 = 4.2s\sqrt{(d+h_2)K} \quad \text{mm}$$

(2) The thickness t of side shell plating below $\frac{1}{4}D$ from base is not to be less than the following:

$$t_1 = 0.06s(L+110)\sqrt{F_b / K} \quad \text{mm}$$

$$t_2 = 5.4s\sqrt{(d+h_1)F_b K} \quad \text{mm}$$

where: s — spacing of longitudinals, in m, to be taken as not less than the standard spacing of longitudinals;

L — length of ship, in m, L need not be taken as greater than 190 m;

d — draught, in m;

F_d, F_b— reduction factors, see 2.2.5.6 of this Chapter;

h_1 — see 2.3.1.2 of this Section;

h_2 — see 2.3.4.2 of this Section;

K — material factor.

(3) The thickness t of side shell plating between $\frac{1}{4}D$ and $\frac{1}{2}D$ from base is to be obtained by interpolation between the values of t_2 in (1), (2) above, but not less than t_1 in (2) above.

(4) For the calculation of t_1, except the minimum range of high tensile steel stipulated in Section 2 of this Chapter, the material factor K may be taken as 1.

2.3.4.4 The thickness of side shell plating within 0.075L from the ship's ends is to comply with the requirements of 2.3.1.4 of this Section.

2.3.4.5 The thickness of side shell plating is not to be less than that obtained by the following formula:

$$t = (0.035L+6)\sqrt{K} \quad \text{mm}$$

where: L — length of ship, in m;

K— material factor.

The thickness of side shell plating beyond 0.4L amidships is to be tapered gradually to the end thickness of side shell plating.

2.3.5 Sheer strake

2.3.5.1 The width of the sheer strake is not to be less than:

b = 800 + 5L mm, but need not be greater than 1,800 mm

where: L — length of ship, in m.

2.3.5.2 Where the side shell is framed transversely, the thickness t of the sheer strake within 0.4L amidships is not to be less than the following:

$$t_1 = 0.085sE^{-1}(L_1+110)\sqrt{\frac{F_d}{K}} \quad \text{mm}$$

$$t_2 = 1.05s\sqrt{(L+75)K} \quad \text{mm}$$

where: s — spacing of frames, in m, to be taken as not less than the standard spacing of frames;

L — length of ship, in m;

L_1 = L, in m, need not be taken as greater than 200 m;

F_d, E — see 2.3.4.2 of this Section;

K — material factor.

2.3.5.3 Where the side shell is framed longitudinally, the thickness t of the sheer strake within 0.4L amidships is not to be less than the following:

$$t_1 = 0.06s(L_1+110)\sqrt{\frac{F_d}{K}} \quad \text{mm}$$

$$t_2 = 0.9s\sqrt{(L+75)K} \quad \text{mm}$$

where: s — spacing of longitudinals, in m, to be taken as not less than the standard spacing of longitudinals;

L — length of ship, in m;

L_1 = L , in m, need not be taken as greater than 200 m in calculation;

F_d — reduction factors, see 2.2.5.6 of this Chapter;

K — material factor.

2.3.5.4 The thickness of sheer strake within 0.4L amidships is in any case not to be less than 0.8 times that of the stringer plate of the strength deck, nor less than that of adjacent side shell plating, and may be gradually tapered to the end thickness of the side shell plating.

2.3.5.5 Where the sheer strake is connected to the stringer plate by welding, the upper edge of the sheer strake is to be dressed smooth, and any fittings welded to the top of the sheer strake within 0.5L amidships are to be avoided. Scupper openings are not to be cut in the sheer strake which is protruded above the deck within 0.5L amidships or in way of breaks of superstructures.

Where a rounded sheer strake is adopted, the radius is not to be less than 15 times the thickness of the plate. The thickness of rounded sheer strake is to be at least equal to that of deck plating. Effective measures are to be taken to maintain the required properties of material after shaping. Deck fittings welded directly to the rounded sheer strake within 0.5L amidships are to be avoided, wherever possible.

2.3.6 Local strengthening

2.3.6.1 The thickness of shell plates connected to the stern frame or fitted in way of the shaft bossing in single screw ships and in way of the palms of propeller struts in multi-screw ships, is neither to be less than 1.5 times the thickness of shell plating at ends, nor to be less than the thickness of the shell plating amidships.

2.3.6.2 The shell plating in way of hawse pipe and one plate below are to be increased in thickness or to be fitted with doubler plates. The outlet of hawse pipe is to have adequate corner

radius. It is recommended that the corner radius of chafing lips made of steel plate or cast steel be not less than 12 times the diameter of anchor chain.

2.3.7 Openings in shell plating

2.3.7.1 Openings cut in the turn of the bilge strake within 0.5*L* amidships are to be avoided as far as possible, but if necessary, the openings are to be elliptical with the major axis arranged in the fore and aft direction.

2.3.7.2 In general, compensation will not be required for circular openings in the sheer strake which are clear of the gunwale and the deck openings outside the line of hatchways and whose depth does not exceed 20% of that of the sheer strake or 380 mm, whichever is the lesser. Circular openings in sheer strake are to be kept well clear of the ends of superstructures. Openings cut in a rounded gunwale are not allowed.

2.3.7.3 Sea inlets and other openings are to have well rounded corners. The thickness of sea inlet box plating and its steel grade are not to be lower than the adjacent shell. For ships of 90 m or over in length, this thickness is not to be less than 12 mm, but need not exceed 25 mm.

2.3.7.4 Cargo door openings are to have well rounded corners, and are to be kept clear of the ends of superstructures and the deck openings outside the line of hatchways. Such openings within 0.5*L* amidships are to be fully compensated by insert plates or doubler plates with a sufficient length in the fore and aft direction.

2.3.8 Bilge keels

2.3.8.1 Where bilge keels are fitted, they are to be attached to a continuous flat bar which may be welded to the shell. All butts of bilge keels, flat bars and shell plating are to be properly shifted from one another. Bilge keels and flat bars are not to be interrupted abruptly, but to be gradually tapered at their ends and terminated on a suitably stiffened panel.

Section 4 DECKS

2.4.1 General requirements

2.4.1.1 This Section applies to all decks with longitudinal or transverse framing.

2.4.1.2 Where the platform decks terminate within 0.4*L* amidships, horizontal brackets are to be provided at their ends and are to extend over a suitable length.

2.4.2 Strength deck

2.4.2.1 The thickness t of strength deck plating outside the line of openings within 0.4*L* amidships is, in addition to complying with the requirements for midship section modulus, not to be less than the following:

(1) For transverse framing:

$$t_1 = 0.085sE^{-1}\,(L_1+110)\sqrt{\frac{F_d}{K}} \quad \text{mm}$$

$$t_2 = 1.05s\sqrt{(L+75)K} \quad \text{mm}$$

where: s — spacing of frames, in m, to be taken as not less than the standard spacing of frames;

L — length of ship, in m;

L_1 = L, in m, need not be taken as greater than 200 m in calculation;

F_d — reduction factor, see 2.2.5.6 of this Chapter;

$E = 1 + \frac{s^2}{S^2}$, where S is spacing of deck longitudinals;

K — material factor.

(2) For longitudinal framing:

$$t_1 = 0.06s(L_1+110)\sqrt{\frac{F_d}{K}} \quad \text{mm}$$

$$t_2 = 0.9s\sqrt{(L+75)K} \quad \text{mm}$$

where: s — spacing of longitudinals, in m, to be taken as not less than the standard spacing of longitudinals;

L — length of ship, in m;

L_1 = L in m, need not be taken as greater than 200 m;

F_d — reduction factor, see 2.2.5.6 of this Chapter;

K — material factor.

2.4.2.2 The thickness t of strength deck plating inside the line of openings and within 0.075L from the ship's ends, irrespective of longitudinal or transverse framing, is not to be less than that obtained from the following formula:

$$t = 0.9s\sqrt{(L+75)K} \quad \text{mm}$$

where: s — spacing of frames, in m, to be taken as not less than the standard spacing of frames;

L — length of ship, in m;

K — material factor.

2.4.2.3 The minimum thickness t of the strength deck plating (including deck plating at ends) is not to be less than 6 mm.

2.4.2.4 Where the long bridge deck within 0.5L amidships is regarded as the strength deck, the midship section modulus and the minimum thickness are to comply with the requirements of 2.2.5 and 2.4.2.1 of this Chapter.

2.4.2.5 The thickness of strength deck plating is to be maintained for 0.4L amidships and is to be gradually tapered to the end thickness.

2.4.2.6 Where the strength deck at the ship's fore end is not protected by a forecastle, the plate thickness of strength deck forward of 0.15L from the fore perpendicular is to meet the requirements for forecastle deck.

2.4.3 Stringer plates

2.4.3.1 The thickness of strength deck stringer plates is not to be less than the thickness of strength deck plating. The breadth of strength deck stringer plates within 0.4L amidships is to comply with the relevant requirements of Section 3, Chapter 1 of this PART. The breadth of strength deck stringer plates at ends of the ship is not to be less than 65% of that amidships.

2.4.4 Deck openings

2.4.4.1 Where the corners of engine/boiler room or hatch openings in the strength deck are parabolic or elliptical, insert plates are not required, but the requirements as shown by Figure 2.4.4.1 are to be complied with.

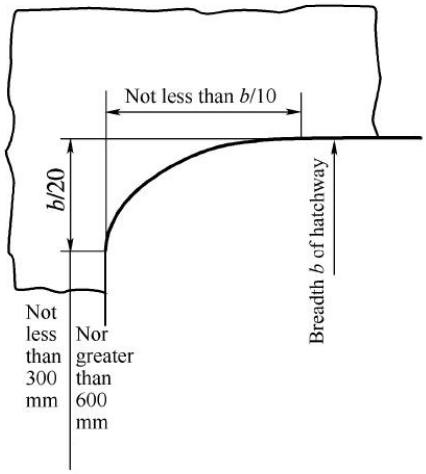


Figure 2.4.4.1

2.4.4.2 Where the corners of engine/boiler room or hatch openings in the strength deck are rounded, insert plates are required, and the radius of the rounded corner is not to be less than 1/20 of the breadth of the opening, but not less than 1/10 provided that deck girders are not fitted in way of the hatch coamings. Rounded corners are to have a minimum radius of 300 mm if the deck plating extends inside the coaming, or 150 mm if the coamings are welded to the inner edge of the deck plating in the form of a spigot.

The extension of the insert plates is to be as shown in Figure 2.4.4.2 (R is the radius of hatch corners, e is not to be less than 760 mm and for longitudinal framing, not to be less than one longitudinal spacing). The butt of the insert plate is to be kept well clear of the butt in coaming and the fillet welds of deck framing. The thickness of the insert plate is to be 4 mm greater than the thickness of strength deck framing. If the thickness or extension of the insert plate can not meet above requirements, direct calculation covering yield, buckling and fatigue is to be adopted for verification.

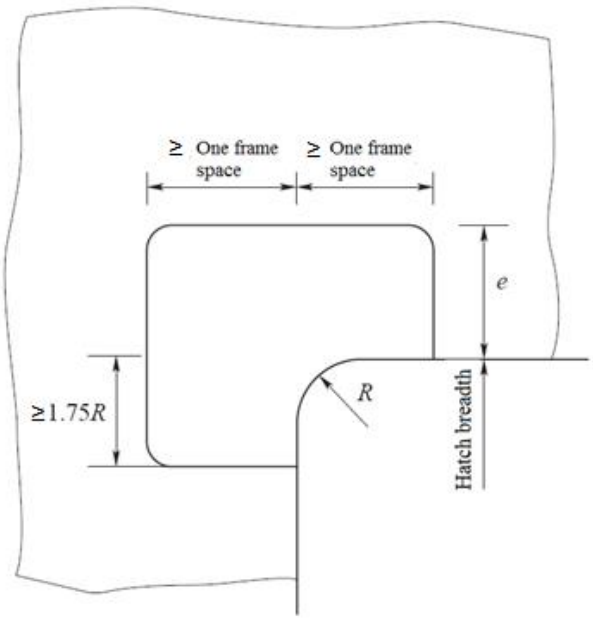

Figure 2.4.4.2

2.4.4.3 Openings in the strength deck outside the line of hatchways are to be kept to a minimum and are to be arranged clear of hatch corners. The corners of all openings are to be well rounded and with the edges smoothed.

Openings in the strength deck between midship bridge or deckhouse end bulkheads and hatches are to be avoided so far as possible.

2.4.4.4 Compensation is not required for openings in the strength deck outside the line of hatchways and situated within 0.5*L* amidships provided that they comply with the provisions of 2.2.4.7 of this Chapter. Edge reinforcement will not be required for:

(1) elliptical openings having their major axis in the fore and aft direction and an aspect ratio not less than 2;

(2) openings of other shapes provided that it has been shown by suitable tests that the stress concentration factor does not exceed 2 for low carbon steel and 1.5 for higher tensile steel.

2.4.4.5 Where the openings in the strength deck within 0.5*L* amidships and outside the line of hatchways do not comply with the provisions of 2.2.4.7 of this Chapter, compensation is required. Compensation is normally arranged by increasing the deck plate thickness. Where the openings do not comply with the provisions of 2.4.4.4(1) or (2) of this Section, the edge reinforcement in the form of a spigot as shown in Figure 2.4.4.5 is to be adopted, or alternative arrangements will be considered. Where a spigot is adopted, the sectional area *A* of the ring plate is not to be less than that obtained from the following formula:

$$A = 0.5rt \quad \text{mm}^2$$

where: r — radius of opening, in mm, and to be taken as the half breadth of the openings for elliptical openings;

t — thickness of deck plating, in mm.

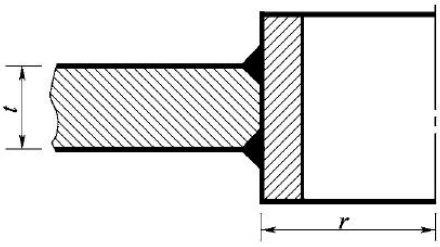

Figure 2.4.4.5

2.4.4.6 Lower deck openings are to comply with the following requirements:

(1) Inserts are required for machinery spaces and cargo hatch opening corners on second tier decks, and the thickness of inserts is to be 2.5 mm greater than the deck thickness. Insert plates will not generally be required for hatch corners on third tier decks and decks below (including platform decks).

(2) Openings outside the line of hatchways are to be as far as practicable kept clear of hatch corners and other areas of high stress. The provisions of 2.4.4.4 and 2.4.4.5 of this Section are generally also applicable to openings in lower decks, but compensation will not be required unless the total breadth of openings (see shadow areas as shown in Figure 2.2.4.7 of this Chapter) in such decks exceeds 15% of the breadth of deck plating used in midship section modulus calculation.

2.4.4.7 The above requirements for deck openings are, in general, also applicable to regions outside 0.5*L* amidships.

2.4.5 Lower decks and platform decks with loading not exceeding 40 kPa

2.4.5.1 The thickness *t* of second tier deck plating outside the line of hatchways and within 0.4*L* amidships is not to be less than that obtained from the following formula:

$$t = 12s\sqrt{K} \quad \text{mm, and not less than 6 mm}$$

The thickness *t* of second tier deck plating inside the line of hatchways and within 0.075*L* from the ship's ends is not to be less than that obtained from the following formula:

$$t = 10s\sqrt{K} \quad \text{mm, and not less than 6 mm}$$

where: *s* — spacing of frames, in m, to be taken as not less than the standard spacing of frames.

2.4.5.2 The thickness *t* of third tier deck or platform deck plating is not to be less than that obtained from the following formula:

$$t = 10s\sqrt{K} \quad \text{mm, and not less than 6 mm}$$

where: *s* — spacing of frames, in m, to be taken as not less than the standard spacing of frames;

K — material factor.

2.4.6 Raised quarter decks

2.4.6.1 For the requirements for raised quarterdecks, see 2.17.8 of this Chapter.

2.4.7 Superstructure ends

2.4.7.1 The deck strengthening at ends of superstructures is to comply with the requirements of 2.17.6 of this Chapter.

2.4.8 Deck coverings

2.4.8.1 The deck coverings are to be of materials which are not corrosive to steel, or they are to be effectively insulated from the steel by a noncorrosive protective coating.

2.4.8.2 Wood sheathing on exposed steel deck is to have a thickness not less than 50 mm for pine and 45 mm for teak wood in ships less than 120 m in length, and 60 mm and 50 mm respectively in ships of 120 m or over in length. For enclosed spaces, the thickness of pine sheathing on the steel deck is not to be less than 40 mm.

The thickness of steel deck plating sheathed with wood planks may be reduced by 1 mm, but each plank is to be well secured to the deck plating at every beam by studs.

2.4.8.3 Where chemical covering is used as a substitute for wood sheathing, the thickness of the steel deck plating is not to be reduced.

Section 5 SINGLE BOTTOMS

2.5.1 Application

2.5.1.1 This Section applies to transversely framed single bottom ships of not greater than 90 m in length.

2.5.2 Centre keelson

2.5.2.1 The centre keelsons are to be provided in way of the central longitudinal section of the ship. The depth of the centre keelson is to be the same as that of floors, and the web thickness t and the sectional area A of the face plate of the centre keelson are not to be less than the following:

Within 0.4L amidships: $t = \sqrt{LK} + 2$ mm, and not less than 6 mm

$A = 0.67LK$ cm^2, and not less than 12.5 cm^2

Within 0.075L from the ship's ends: $t = \sqrt{LK} + 0.5$ mm, and not less than 6 mm

$A = 0.52LK$ cm^2, and not not less than 12.5 cm^2

where: L — length of ship, in m;

K— material factor.

In the forepeak tank, the centreline keelson may have the same depth and thickness and the same sectional area of face plate as the floor.

2.5.2.2 The centre keelson is normally to extend as far forward and aft as practicable. Where the centre keelson is cut in way of a bulkhead, it is to be connected to the bulkhead by one of the following means:

(1) The web plate of the centre keelson is to be gradually raised, within one frame spacing to 1.5 times the original web depth at the bulkhead, and the face plate of the centre keelson is to extend and to be welded to the bulkhead, as shown in Figure 2.5.2.2(1).

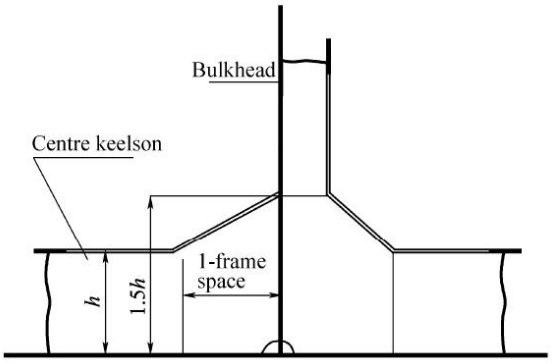

Figure 2.5.2.2(1)

(2) The centre keelson is to be attached to the bulkhead by brackets having a face plate or flange, and the depth and length of the brackets are to be equal to the depth of the keelson. In this case, the face plate of the centre keelson may not be welded to the bulkhead. The thickness of the brackets is to be the same as that of the web of the centre keelson, as shown in Figure 2.5.2.2(2).

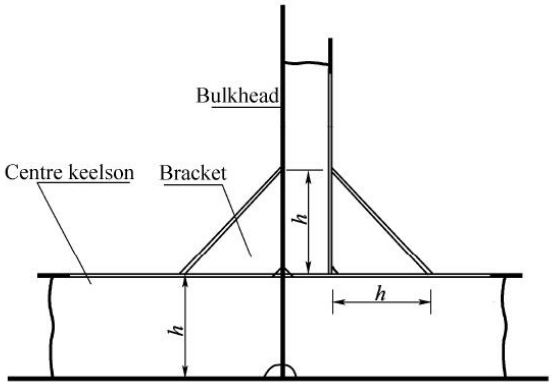

Figure 2.5.2.2(2)

(3) The face plate of the centre keelson is, within one frame spacing, to be gradually widened to twice its original width at the bulkhead, and to be welded to the bulkhead, as shown in Figure 2.5.2.2(3).

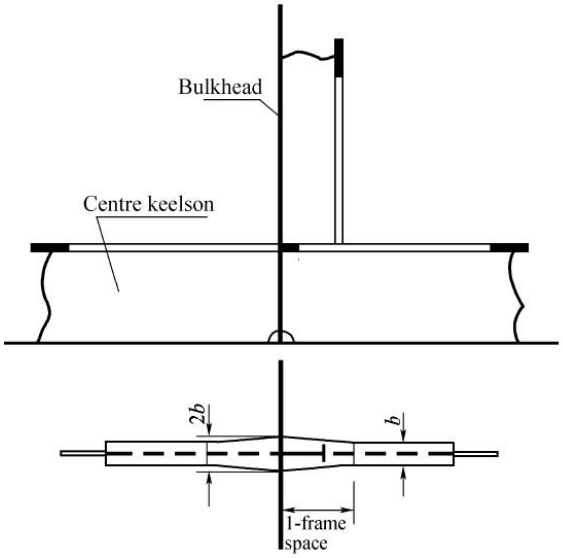

Figure 2.5.2.2(3)

2.5.2.3 In the machinery space the thickness of the centre keelson web is to be equal to the value obtained from 2.5.2.1 of this Section plus 1 mm. Where a single main engine is fitted, the centre keelson may be omitted in the machinery space provided that the longitudinal girders under the engine seating extend over the whole length of the engine room and brackets are fitted at the outside of both end bulkheads of the engine room for transition. Within the engine room where the centre keelson is cut, however, gradually tapered brackets having a length not less than two frame spaces are to be fitted for transition, as shown in Figure 2.5.2.3.

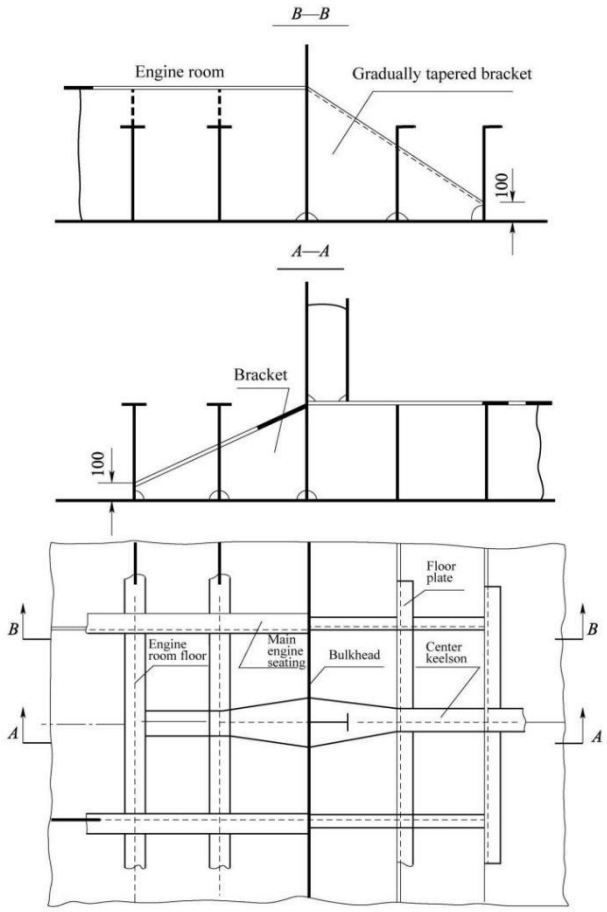

Figure 2.5.2.3

In machinery spaces situated at the aft end, such engine seating girders are to be carried as far aft as practicable and the ends effectively supported by web frames or transverses. Where it is impracticable to provide transition brackets abaft the aft peak bulkhead because the aft body of the ship is too fine, such brackets may be dispensed with.

2.5.3 Side keelsons

2.5.3.1 The depth of side keelsons is to be the same as that of floors, and the web thickness t and the face plate sectional area A of side keelsons are not to be less than the following:

$$t = \sqrt{LK} \quad \text{mm, and not less than 6 mm}$$

$$A = 0.25L + 5 \text{ cm}^2, \text{ and not less than 10 cm}^2$$

where: L — length of ship, in m;

K— material factor.

In the machinery space, the web thickness of side keelsons is not to be less than that of the centre keelson as required in 2.5.2.1 of this Section.

2.5.3.2 One side keelson at least is to be fitted on each side of the centre keelson where the breadth of ship is equal to 9 m or less, and two at least where the breadth exceeds 9 m but does not exceed 16 m. In addition, continuous or intercostal longitudinal stiffeners are to be fitted where the panel aspect ratio exceeds 4. Side keelsons are to be uniformly fitted and are to extend as far forward and aft as practicable. Outboard of the main engine seating girders, side keelsons as

required in 2.5.3.1 of this Section are to be fitted, and attention is to be given to structural continuity. In the case of ships having duplicate main engines situated at the aft end, where it is impracticable to fit the side keelsons owing to the confined space in the engine room, such keelsons may be dispensed with.

2.5.3.3 The attachment of side keelsons to the bulkheads is to be the same as required for the centre keelson (see 2.5.2.2 of this Section).

2.5.4 Floors

2.5.4.1 Plate floors are to be fitted at every frame and are, at the centreline, to have a web depth h, a web thickness t and a sectional area A of face plate not less than:

$$h = 42(B + d) - 70 \quad \text{mm}$$

$$t = (0.01h+3)\sqrt{K} \text{ mm, but not less than 6 mm and need not be greater than 14 mm}$$

$$A = (4.8d-3)\,K \quad \text{cm}^2$$

where: B — breadth of ship, in m;

d — moulded draught, in m;

K — material factor.

2.5.4.2 The thickness of the face plate of the floor is not to be less than that of its web plate. The breadth of the face plate is not to be less than 10 times its thickness, but need not exceed 15 times.

2.5.4.3 In ships having considerable rise of floor (or towards fore and aft ends), the depth of floor plates is to be increased. The floor plates forming part of a watertight, deep tank or tank bulkhead are not to be less than 900 mm in depth measured at the centreline, and have a thickness not less than that required for the bottom strake of a bulkhead.

For small ships, the depth of the floor plates at the centreline may be suitably reduced.

2.5.4.4 In machinery spaces the web thickness of floors is not to be less than that of the centre keelson as required in 2.5.2.1 of this Section. In way of machinery spaces situated amidships, the depth of the web plate and the face plate sectional area of floors are to be increased by 10% above those obtained from 2.5.4.1 of this Section. In way of machinery spaces situated astern, the face plate area of floors is to be increased by 10% above those obtained from 2.5.4.1 of this Section. The floors are not to be flanged instead of having face plates.

In way of machinery spaces situated aft or where there is considerable rise of floor, the depth of floors is to be appropriately increased in accordance with the ship's lines and strength.

2.5.5 Bilge brackets

2.5.5.1 Floors are to be connected to the frames by bilge brackets. The depth of the bilge brackets measured from the base line is to be twice that of the floors in way of the centreline, and the length of the brackets, measured from the inner edge of frames, is to be equal to the floor depth on the centreline. The thickness of the brackets is to be equal to that of floors. The brackets are to have a flange or face plate. When flanged, the width of the flange is neither to exceed 10 times the thickness of the bracket nor to be less than 50 mm.

2.5.5.2 Where it is impracticable to arrange the bilge brackets due to the ship's lines or other reasons, the floors are to extend to the ship's side and to be raised to the required depth for bilge brackets.

2.5.5.3 Where bilge brackets or floors are connected to the frames by means of a welded lap joint, the length of overlap is to be as follows:
(1) when the depth of frames is 100 mm or less, the length of overlap is not to be less than twice the depth of frames;
(2) when the depth of frames exceeds 100 mm, the length of overlap is neither to be less than 1.5 times the depth of the frame nor less than 200 mm.

2.5.6 Drain holes

2.5.6.1 Drain holes are to be cut in the floors and side keelsons in way of the bottom. Provision is to be made for the free passage of water from all parts of the bottom to the suctions, taking into account the pumping rates required.

Section 6 DOUBLE BOTTOMS

2.6.1 General requirements

2.6.1.1 Double bottoms are to comply with the requirements of this Section and in addition, the relevant requirements of Section 12, Chapter 1 of this PART.
2.6.1.2 Where the double bottom is interrupted, the continuity of bottom longitudinal members is to be maintained. The centre and side keelsons within the single bottom in way of the break are to be the continuation of the centre and side girders of the double bottom. The inner bottom plating is to extend beyond the break of the double bottom and to be gradually tapered for a length of not less than three frame spaces to form the face plate of the keelsons, and the breadth of the face plate at the break of the double bottom is not to be less than half the spacing of side keelsons. The margin plate is also to extend not less than three frame spaces beyond the break of the double bottom. Where the margin plate is inclined, the extension portion is to have a face plate or flange, and the width of the margin plate may be reduced gradually. Within the single bottom, side keelsons, which are not the direct continuation of the girders in the double bottom, are to be extended into the double bottom and to be gradually tapered off over a length of not less than three frame spaces with their free edges flanged.
2.6.1.3 Sufficient girders are to be arranged in way of the main machinery and structural continuity is to be maintained. In midship machinery spaces, these girders are to extend for the full length of the space and are to be carried for at least three frame spaces beyond the fore and after bulkheads of the engine room. However, the extension beyond the after bulkhead is also to support the foremost shaft tunnel bearing; in machinery spaces situated at the aft end such girders are to be carried as far aft as practicable and the ends effectively supported by web frames or transverses.
Outboard of the main engine seating girders, side girders are to be arranged and attention is to be given to the structural continuity.
2.6.1.4 Manholes are to be cut in the floors and side girders. Except for lightened floors, the depth of manholes is not to exceed 50% of that of the double bottom, unless edge reinforcement is provided. Manholes cut in floors are to be arranged along a straight line in the fore and aft direction for easy access. Manholes or lightening holes are not permitted within the range of floor

ends (generally taken as 1 spacing of longitudinals in way of the longitudinal bulkhead or 600 mm, whichever is greater) and in the side girders for one frame space from transverse bulkheads, unless the edges of holes are strengthened. The edges of all holes are to be smoothed.

2.6.1.5 Air and drain holes are to be cut in floors, side girders and bottom and inner bottom longitudinals to ensure the free passage of air and water from all parts of the tanks to the air pipes and suctions, account being taken of the pumping rates required.

2.6.1.6 The minimum thickness of floors and girders of double bottoms is to be 6 mm.

2.6.1.7 The strake connecting the inner bottom plating to the shell plating is the margin plate.

2.6.2 Centre girders

2.6.2.1 Centre girders are to be provided in way of the central longitudinal section of the ship. The depth h_0 of centre girders is to comply with the requirements for the depth of double bottoms in Section 12, Chapter 1 of this PART and not to be less than that calculated by the following formula:

$$h_0 = 25B + 42d + 300 \quad \text{mm, nor less than 760 mm}$$

where: B — breadth of ship, in m;

d — draught, in m.

For double hull ships (with double bottom and double side skin), the distance from midpoint between outer and inner shells at one side to that at the other side may be taken as equivalent breadth in lieu of the breadth B of ship (see Figure 2.6.2.1). B_e is generally not to be less than $0.9B$, and if the double bottom strength is in compliance with the CCS criteria for direct strength calculations, not to be less than $0.8B$.

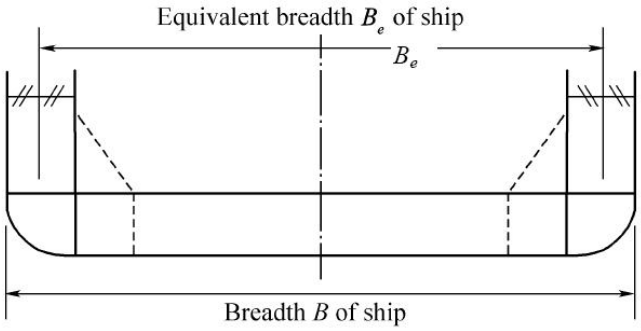

Figure 2.6.2.1

2.6.2.2 The thickness t of centre girders is not to be less than:

(1) For $0.4L$ amidships:

$$t = (0.0077h_0+4)\sqrt{K} \quad \text{mm}$$

where: h_0 — considered height of double bottom, in mm;

K — material factor.

(2) For $0.075L$ from the ship's ends, the thickness t of centre girders may be decreased by 2 mm from that required in (1) above.

(3) The thickness of centre girders in boiler spaces is to be increased by 2.5 mm above that required for centre girders within $0.4L$ amidships.

2.6.2.3 The centre girders within $0.75L$ amidships are to be continuous and to extend as far as practicable to the stem and stern frame.

2.6.2.4 Manholes or lightening holes are not to be cut in the centre girders within 0.75L amidships, but if such holes are essential in exceptional cases, suitable compensation is to be provided.

Outside 0.75L amidships, holes may be cut in centre girders (excluding one frame space forward and aft of a transverse bulkhead) with a depth not exceeding 40% of that of the centre girders at that place.

2.6.3 Duct keels

2.6.3.1 Duct keels (pipe tunnels) may be substituted for centre girders. The thickness of side plates of the duct keel is not to be less than that of the watertight floors. The side plates are in general not to be spaced more than 2 m apart; for ships of 150 m or above in length, the side plates may be spaced not more than 3 m apart upon verification by direct calculation.

The bottom shell and inner bottom within the region of duct keels are to be suitably increased in thickness.

2.6.3.2 The framing members of the duct keel are to be as follows:

(1) Bottom and inner bottom stiffening members are to be fitted to the duct keel at every frame, and the section modulus W of these framing members is not to be less than that obtained from the following formula:

$$W = 22sdl^2K \qquad \text{cm}^3$$

where: s — spacing of frames, in m;

d — draught, in m;

l — span, in m, to be taken as the distance between side plates;

K — material factor.

(2) Bottom and inner bottom stiffening members are to be gradually increased in scantlings at both ends and are to be connected to the side plates of the duct keel. The enlarged portions are to have a length and depth not less than 1.5 times the depth of the members. In such a case, brackets having the same thickness as the plate floors are to be fitted outside the side plates at each frame where no floor is fitted, and are to be attached to the longitudinals.

(3) Bottom longitudinals are to be fitted within the duct keel on the centreline of the ship, which may be intercostal in way of transverse framing members.

2.6.3.3 At the connection between the duct keel and the ordinary centre girder, they are to be overlapped over a length not less than 3 frame spaces for transition.

2.6.4 Transverse framing — side girders

2.6.4.1 The thickness of side girders is not to be less than that obtained from the following formula:

$$t = (0.0077h_0+1)\sqrt{K} \qquad \text{mm}$$

where: h_0 — considered height of double bottom, in mm.

K — material factor.

The thickness of watertight side girders is to be increased by 1 mm above that obtained from the above formula. Where the double bottom tanks are interconnected with side tanks or cofferdams, the thickness of side girders is to be as required for deep tanks.

2.6.4.2 At least one side girder is to be fitted on each side of the centreline when the breadth of the ship exceeds 10 m, and at least two side girders spaced apart generally not more than 4 m are

to be fitted on each side of the centreline when the breadth of the ship exceeds 18 m. But forward of 0.2L from the F.P., the spacing of side girders is not to be greater than 3 frame spaces. Side girders are to be equally spaced as far as practicable.

2.6.5 Transverse framing — plate floors

2.6.5.1 The thickness t of plate floors in cargo holds or machinery spaces is not to be less than that obtained from the following formula, but need not exceed 15 mm:

$$t = (0.0077h_0+1)\sqrt{K} \quad \text{mm}$$

where: h_0 — considered height of double bottom, in mm;

K — material factor.

The thickness of plate floors in boiler rooms and in way of the bilge wells is to be 2.5 mm greater than that given by the above formula.

2.6.5.2 Plate floors are to be fitted at least 4 frame spaces apart at a spacing not exceeding 3.2 m. Where the length of ships exceeds 90 m or the depth of floors exceeds 0.9 m, vertical stiffeners spaced not more than 1.5 m apart are to be fitted on the plate floors, generally having the same thickness as that of floors and the width of which is not to be less than 150 mm. For ships less than 90 m in length, the width of such stiffeners is not to be less than 1.65L, with a minimum of 50 mm.

Plate floors are to be fitted at every frame in the engine room and under the boiler bearers, thrust seatings, transverse bulkheads and heels of pillars. Plate floors are to be fitted at every frame forward of 0.2L from the F.P.

2.6.6 Transverse framing — watertight floors

2.6.6.1 The thickness of watertight floors is to be as follows:

(1) The thickness of watertight floors is to be 2 mm greater than that of the plate floors in cargo holds, but generally need not exceed 15 mm.

Watertight floors are to be fitted below transverse watertight bulkheads wherever practicable.

(2) The thickness of oiltight floors in oil tanks is to be the same as required for the above watertight floors.

2.6.6.2 Where the depth of watertight floors is greater than 0.9 m but does not exceed 2 m, they are to be fitted with vertical stiffeners spaced not more than 0.9 m apart. Both ends of stiffeners are to be snipped, the thickness and depth are to comply with the requirements of 2.6.5.2 of this Section, and the section modulus W of which is not to be less than that obtained from the following formula:

$$W = 5.5shl^2K \quad \text{cm}^3$$

where: s — spacing of stiffeners, in m;

h — vertical distance, in m, from the inner bottom to the top of overflow;

l — span of stiffener, in m, i.e. the considered height of double bottom;

K — material factor.

The section modulus of the stiffeners on the oiltight floors in oil tanks is to be the same as required in the above formula.

2.6.6.3 Where the double bottom tanks are interconnected with side tanks or cofferdams, or the depth of the plate floor is greater than 2 m, the scantlings of the watertight floors are not to be less than those required for deep tanks, furthermore, vertical stiffeners are to be bracketed at both ends.

2.6.7 Bracket floors

2.6.7.1 Where transverse framing is adopted in the double bottom, bracket floors are to be fitted at every frame where no plate floor is fitted. The breadth of the brackets attaching the frames and the reversed frames to the centre girder and margin plate is not to be less than 75% of the depth of the centre girder, and the thickness of the brackets is to be the same as that of plate floors in that region. Where the depth of the double bottom is equal to 800 mm or more, the brackets are to have a flange or face plate on the unsupported edge and the breadth of the flange or face plate is to be 10 times the thickness but need not exceed 90 mm. Stiffeners having the same scantlings as the reversed frames are to be fitted on one side of the side girders (see Figure 2.6.7.1). Where l as shown in the Figure is greater than 2.5 m, struts as required in 2.6.7.2 of this Section are to be fitted.

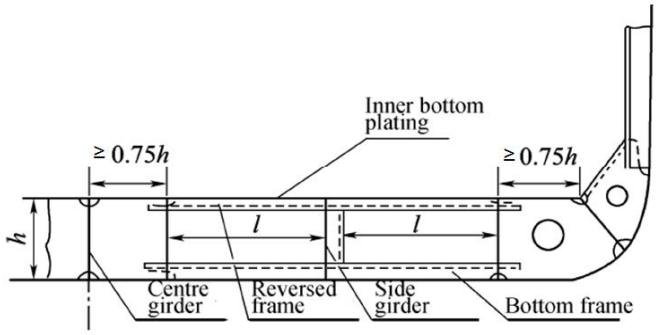

Figure 2.6.7.1

2.6.7.2 The bottom frames of bracket floors are to have a section modulus W not less than that obtained from the following formula:

$$W = (15 - 2.5l_1)sdl^2K \quad \text{cm}^3$$

where: s — spacing of frames, in m;

d — draught, in m;

l — span of bottom frames, in m, measured from the edge of the bracket to the side girder (see Figure 2.6.7.1);

l_1 — the same as l, but l_1 is to be taken as 2.5 m for $l > 2.5$ m;

K — material factor.

Where struts are fitted at the mid-point of the span l, the section modulus W of the bottom frames is not to be less than half of that given by the above formula. The cross sectional area A of the struts is not to be less than the following:

$$A = 23.8 + 0.04W \text{ cm}^2 \quad \text{for } W > 85 \text{ cm}^3$$

$$A = 0.32W \text{ cm}^2 \quad \text{for } W \leq 85 \text{ cm}^3$$

where: W — section modulus of bottom frames, in cm³.

The reversed frames are to have a section modulus not less than 85% of that given above for the bottom frames.

In boiler rooms, the thickness of the bottom frames, reversed frames and struts is to be increased by 2 mm.

2.6.7.3 The attachment of bottom frames and reversed frames to brackets is to be the same as required in 2.5.5.3 of this Chapter for the attachment of frames to bilge brackets.

2.6.8 Lightened floors

2.6.8.1 Where transverse framing is adopted in the double bottom, lightened floors may be fitted at every frame where no plate floor is fitted, as substitutes for bracket floors. The thickness of the web plate of lightened floors is not to be less than that of the plate floor in the same region. The distance from the edge of the lightening hole to bottom and inner bottom is not to be less than 0.2 times the depth of the centre girder; the distance from the edge of the lightening hole to the centre girder and margin plate is not to be less than 0.5 times the depth of the centre girder; the distance from the edge of the lightening hole to the side girder is not to be less than 0.25 times the depth of the centre girder; and the length of the the lightening hole is not to exceed 1.2 times the depth of the centre girder, as shown in Figure 2.6.8.1.The dimensions of the vertical stiffeners on the floors are to comply with the requirements of 2.6.5.2 of this Section, and the spacing of the stiffeners is not to be more than 2.2 m.

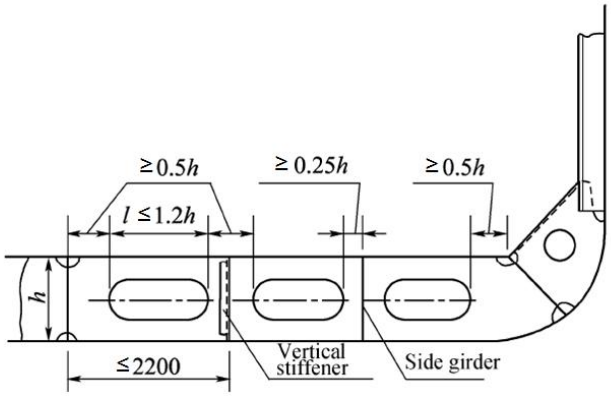

Figure 2.6.8.1

2.6.9 Transverse framing — inner bottom plating and margin plate

2.6.9.1 The thickness t of the inner bottom plating is not to be less than the following:

$t = (0.04L+5s+2.1)\sqrt{K}$ mm for 0.4L amidships

$t = (0.055L+4.8)\sqrt{K}$ mm for engine spaces

where: L — length of ship, in m, to be taken as not greater than 400 m;

s — spacing of frames, in m;

K — material factor.

For 0.075L from the ship's ends, the thickness is to be 0.9 times that required for 0.4L amidships. The thickness of the inner bottom plating in other regions is to be tapered gradually to the end thickness from the thickness within 0.4L amidships.

2.6.9.2 Local strengthening of inner bottom plating:

(1) Where the double bottom tanks are used to carry oil fuel, the thickness of the inner bottom plating is not to be less than 8 mm.

(2) The thickness of the inner bottom plating under hatchways is to be increased at least by 2 mm if no wood ceiling is fitted. If cargo is regularly discharged by grabs or other similar means and where no wood ceiling as required in 3.3.1.5 of this PART is fitted, the thickness of the inner bottom plating under hatchways is to be increased at least by 5 mm.

2.6.9.3 Where the margin plate is inclined downwards, the breadth of the margin plate is not to be less than 80% of the depth of the centre girder. Where the margin plate is horizontal, the breadth is not to be less than that of bilge brackets plus 50 mm.

Where the margin plate is inclined downwards, the thickness of the margin plate throughout the hold is to be 1.5 mm greater than that required for the inner bottom plating when the length of the ship is equal to 110 m or less, and 2 mm when the length of the ship is greater than 110 m. In engine rooms and boiler rooms, the thickness of the margin plate is not to be less than that required for the inner bottom plating within such spaces respectively.

2.6.10 Longitudinal framing — bottom girders

2.6.10.1 The depth and thickness of the centre girder are to be the same as required in 2.6.2.1 and 2.6.2.2 of this Section. Between plate floors, brackets having the same thickness as the plate floors are to be fitted on each side of the centre girder, extending to the adjacent longitudinals. Such brackets are in general to be spaced not more than 1.20 m apart. Where the centre girder is watertight, vertical stiffeners spaced not more than 0.9 m apart are to be fitted between the plate floors and brackets (when the distance between them is greater than one frame space). For these stiffeners, the section modulus is to comply with the requirements of 2.6.6.2, the thickness is to be the same as that of the center girder web and in general, the breadth is to comply with the requirements of 2.6.5.2.

2.6.10.2 At least one side girder is to be fitted on each side of the centreline when the breadth of the ship exceeds 12 m but not greater than 20 m, and at least two side girders spaced apart generally not more than 5 m are to be fitted on each side of the centreline when the breadth of the ships exceeds 20 m. Forward of 0.2L from the F.P. the spacing of side girders is not to be greater than four longitudinal spaces. The side girders are to be equally spaced as far as practicable.

The thickness of side girders and watertight side girders are to comply with the requirements of 2.6.4.1 of this Section. Where the double bottom tanks are interconnected with side tanks or cofferdams, the thickness of side girders is to be as required for deep tanks.

Side girders and watertight side girders are in general to be fitted with vertical stiffeners. Vertical stiffeners of side girders are to be spaced not more than 1.5 m apart, having the same thickness as that of side girder webs and generally, a breadth is to comply with the requirements of 2.6.5.2. Vertical stiffeners of watertight side girders are to be spaced not more than 0.9 m apart, the thickness is to be the same as that of watertight side girder web and generally, the breadth is to comply with the requirements of 2.6.5.2 and the section modulus W is to comply with the requirements of 2.6.6.2.

Where side girders and watertight side girders are fitted with horizontal stiffeners, the thickness of stiffeners is generally the same as that of side girder webs and the breadth is to comply with the requirements of 2.6.5.2. The section modulus W of horizontal stiffeners on watertight side girders is to comply with the requirements of 2.6.6.2.

2.6.11 Longitudinal framing — plate floors

2.6.11.1 In machinery spaces, plate floors are to be fitted at least at alternate frames, and are to be fitted at every frame under the main engine seating, boiler bearers, thrust seatings, transverse bulkheads and heels of pillars.

Plate floors are to be fitted at alternate frames within the region forward of 0.2L from the F.P. Elsewhere, the spacing of the plate floors is not to exceed 3.6 m.

2.6.11.2 The thickness of plate floors for longitudinally framing is to be 10% greater than that required in 2.6.5.1 of this Section, but need not exceed 15 mm, and the thickness of watertight and oiltight floors is to be the same as required in 2.6.6.1 of this Section.

Vertical stiffeners are to be fitted at each longitudinal. The thickness of vertical stiffeners for floors is to be the same as that of the floors and the width of which is to comply with the requirements of 2.6.5.2. In addition, the scantlings of vertical stiffeners for watertight floors are to comply with the requirements of 2.6.6.2 of this Section. Vertical stiffeners are to be attached to the inner bottom and shell longitudinals by welding.

The ratio of thickness to depth of the floors is not to be less than 1/130. Where the double bottom tanks are interconnected with side tanks or cofferdams, the thickness of watertight floors and the stiffeners are to be as required for deep tanks.

2.6.12 Longitudinal framing — bottom longitudinals

2.6.12.1 The spacing of bottom longitudinals is not to be greater than 1 m.

2.6.12.2 The section modulus W of bottom longitudinals is not to be less than that obtained from the following formula:

$$W = \frac{8.5f}{1.73 - F_b}(d + h_1)sl^2K \quad \text{cm}^3$$

where: s — spacing of longitudinals, in m;

l — span of longitudinal, in m, but not less than 1.5 m;

d — draught, in m;

f — factor, taken as 0.52 when intermediate vertical struts are fitted, or 1.0 when no intermediate vertical strut is fitted;

F_b — reduction factor, see 2.2.5.6 of this Chapter;

h_1 — see 2.3.1.2 of this Chapter;

K — material factor.

Where the spacing of plate floors is greater than 2.5 m, vertical struts connecting the bottom longitudinals and inner bottom longitudinals may be fitted at the midpoint of the spacing, and the cross sectional area A of the vertical struts is not to be less than the following:

$A = 23.8 + 0.04W$ cm² for $W > 85$ cm³

$A = 0.32W$ cm² for $W \leq 85$ cm³

where: W — section modulus of longitudinals, in cm³.

2.6.12.3 The section modulus of inner bottom longitudinals is to be equal to 85% of that of the bottom longitudinals. In boiler rooms, the thickness of the longitudinals, struts and brackets is to be increased by 2 mm.

2.6.12.4 Where longitudinals pass through non-watertight floors, they are to be welded to the floors and the vertical stiffeners on the floors in way. Where longitudinals are cut in way of watertight floors, they are to be bracketed to the watertight floors. The scantlings of the brackets are to comply with the requirements of 1.2.6 of this PART. Where the length of the ship exceeds 200 m or higher tensile steel is used, the bottom longitudinals are to be continuous in way of watertight floors, or alternative arrangements may be considered.

2.6.13 Longitudinal framing — inner bottom plating and margin plate

2.6.13.1 The thickness of the inner bottom plating is to comply with the requirements of 2.6.9 of this Section. But for the calculation of the thickness of the inner bottom plating within 0.4*L* amidships, the *s* in the formula is to be taken as the spacing of longitudinals, and the value considered may be reduced by 1 mm.

2.6.13.2 The thickness of the margin plate is to comply with the requirements in 2.6.13.1 of this Section and in addition, is to be increased in accordance with the requirements of 2.6.9.3 of this Section.

2.6.13.3 The margin plate is to be provided with brackets at every frame, extending to the adjacent longitudinal, as shown in Figure 2.6.13.3. The edges of the brackets are to be strengthened, and the thickness of the brackets is to be the same as that of floors.

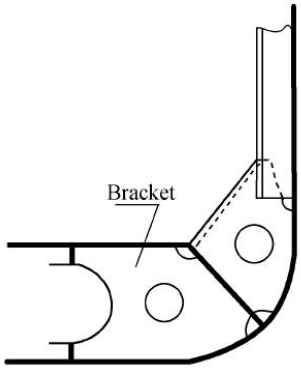

Figure 2.6.13.3

2.6.14 Reinforcement for using fork lift trucks in cargo holds

2.6.14.1 Where fork lift trucks are used for handling cargo in holds, the inner bottom plating and framing are to comply with the relevant requirements of Section 21 of this Chapter for vehicle decks.

2.6.15 Tank side brackets

2.6.15.1 Tank side brackets are to be fitted at every frame and their thickness is to be the same as that of plate floors. Circular lightening holes may be cut in the tank side brackets and the distance from any point of hole edges to the side of brackets is not to be less than 1/3 breadth of the bracket.

2.6.15.2 Tank side brackets are to be flanged or provided with a face plate on the free edge, and the breadth of the flange or face plate is generally to be 10 times the thickness of the bracket.

2.6.15.3 The standard depth and breadth of tank side brackets are to be as follows:

The depth of tank side brackets connecting secondary members is to be equal to 10% of the distance between the inner bottom and nearest deck or 2.2 times the depth of the web of frames, whichever is the greater. The depth of tank side brackets connecting primary members is to be equal to 1.65 times the depth of the web of web frames. The breadth of tank side brackets is to be equal to their depth. The breadth and depth of tank side brackets are to be measured in accordance with Figure 2.6.15.3. Where the inner bottom margin plate of the double bottom is horizontal, vertical stiffeners are to be fitted to the floors under the toes of the brackets (as shown in Figure 2.6.15.3). The requirements for the stiffeners are to be the same as required in 2.6.5.2 of this Section.

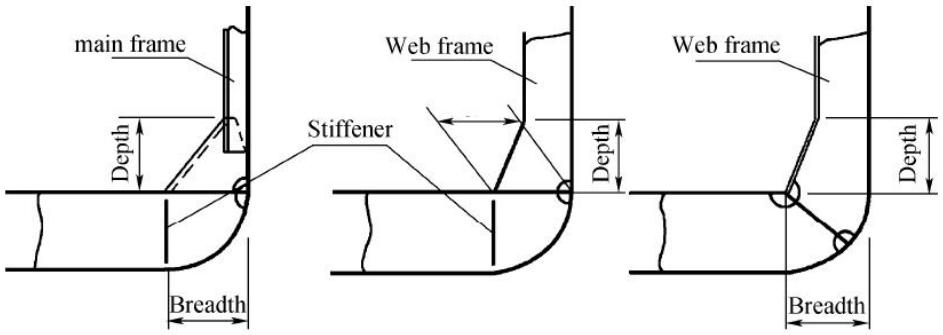

Figure 2.6.15.3

2.6.15.4 Where lap joint is adopted for the connection of tank side brackets to frames, the length of overlap is to comply with the requirements of 2.5.5.3 of this Chapter.

2.6.15.5 Where bottom and sides of the ship are framed longitudinally and no bilge longitudinals are fitted, the transverse strength members or corresponding bilge brackets in way are to have a spacing S not exceeding:

$$S = 8 \times 10^6 \frac{t^2}{Dr}\sqrt{\frac{t}{r}} \quad \text{mm}$$

where: t — thickness of bilge plating, in mm;

D — moulded depth, in m;

r — radius of the bilge, in mm.

Furthermore, a suitable number of intermediate bilge brackets connected to the longitudinals situated at the upper and lower turns of the bilge are to be fitted between the plate floors.

Section 7 SIDE FRAMING

2.7.1 General requirements

2.7.1.1 The maximum spacing of frames or side longitudinals is not to be greater than 1.0 m.

2.7.2 Frames

2.7.2.1 The section modulus W of main frames (except those in fore and after peaks) is not to be less than that obtained from the following formula:

$$W = cc_1 sdl^2 K \quad \text{cm}^3$$

where: s — spacing of frames, in m;

d — draught, in m;

l — span of frames, but in no case is it to be taken as less than $\sqrt{D}$ (D being moulded depth), in m. For frames between collision bulkhead and 0.2L from F.P., it is to be the greatest frame span of the similar structural arrangment in that region:

$$c = \frac{2 + \frac{0.65d}{D}}{1.45 - \frac{\sqrt{D}}{l}}$$

c_1 — coefficient: $c_1 = 1.05$ for $L < 90$ m; $c_1 = 1.00$ for $L \geq 90$ m;

K — material factor.

2.7.2.2 Corrections to the section modulus of main frames:

(1) Where the depth of tank side brackets is less than that required in 2.5.5.1 or 2.6.15.3 of this Chapter, the section modulus of main frames is to be increased by 2.7% of the value required in 2.7.2.1 of this Section for each reduced 100 mm.

(2) Where the arm length of the brackets connecting main frames to beams or deck longitudinals at side is greater than that required in 1.2.6.7 of this PART, the section modulus of main frames may be decreased by 1.3% of the value required in 2.7.2.1 of this Section for each increased 100 mm of difference.

2.7.2.3 Where side stringers are uniformly fitted in compliance with the requirements of 2.7.3.1 of this Section, the section modulus of main frames may be reduced in accordance with the following:

(1) Where one stringer is fitted, the section modulus of main frames may be 1/2 of the value required in 2.7.2.1 or 2.7.2.2 of this Section.

(2) Where two stringers are fitted, the section modulus of main frames may be 2/7 of the value required in 2.7.2.1 or 2.7.2.2 of this Section.

(3) Where three stringers are fitted, the section modulus of main frames may be 1/5 of the value required in 2.7.2.1 or 2.7.2.2 of this Section.

2.7.2.4 The section modulus of the main frames under hatch end beams is not to be less than 1.67 times that of normal main frames as required in this Section.

2.7.2.5 In midship machinery spaces where web frames are not fitted in accordance with 2.7.4.2 of this Section, the section modulus of mains frames in the machinery spaces is to be 50% greater than that normally required.

2.7.2.6 The scantlings of main frames are in no case to be less than those of 'tween decks above, and the main frame section modulus is not to be less than 20 cm^3.

2.7.2.7 The moment of inertial I of main frames is not to be less than that obtained from the following formula:

$$I = 3.2Wl/K \quad cm^4$$

where: W — section modulus of main frames as required in this Section, in cm^3;

l — span of frames, in m, as required in 2.7.2.1 of this Section where fitted with no side stringer, or being the vertical distance measured from the upper edge of floor or top of inner bottom to the side stringer or between side stringers or from the side stringer to the lowest deck at side where fitted with side stringers;

K — material factor.

2.7.2.8 The frames in fore and after peaks are to comply with the following requirements:

(1) The section modulus W and the moment of inertia I of frames below the lowest deck in fore and after peaks are to be respectively not less than the values obtained from the following formulae:

$$W = 4.6sdDK \quad cm^3$$

$$I = 3.5Wl/K \qquad \text{cm}^4$$

where: s — spacing of frames, in m;

d — draught, in m;

D — moulded depth, in m;

L — span of frames, in m, being the vertical distance measured from the upper edge of floor to the side stringer (perforated flat), or distance between side stringers (perforated flats) or from the side stringer (perforated flat) to the lowest deck;

K— material factor.

(2) Where the lowest deck in the fore peak is below 1.0 m above the full-load waterline, the 'tween deck frames fitted from the lowest deck up to 1.0 m above the full-load waterline are also to comply with the requirements of (1) above.

(3) Other 'tween deck frames in the fore peak are also to comply with the requirements of 2.7.2.9 of this Section.

2.7.2.9 The section modulus W of the frames in 'tween decks and superstructures is not to be less than that obtained from the following formula:

$$W = CC_1sdl\sqrt{D}\,K \quad \text{cm}^3$$

where:

s — spacing of frames, in m;

d — draught, in m;

l — span of frame, in m. For frames in 'tween deck space where the actual span is less than 2.6 m, l = 2.6 m is to be taken and for those in superstructures where the actual span is less than 2.3 m, l = 2.3 m is to be taken;

D — moulded depth, in m;

C — coefficient, to be taken as $C = 0.7 + 4\frac{d}{D}$;

C_1 — coefficient, to be determined by the position of frame: C_1 = 1.0 for those in the first 'tween deck below the upper deck; C_1 = 1.1 for those in the second 'tween deck; C_1 = 1.45 for those in the third and lower 'tween decks; C_1 = 0.90 for those in forecastle; C_1 = 0.80 for those in bridge and poop;

K — material factor.

2.7.2.10 The section modulus of the frames under hatch end beams in 'tween deck spaces is not to be less than 1.67 times that of normal 'tween deck frames, as required in this Section.

2.7.2.11 In midship machinery spaces where web frames are not fitted in accordance with 2.7.4.2 of this Section, the section modulus of the 'tween deck frames under the lowest deck above the load waterline is to be 50% greater than that normally required.

2.7.2.12 Where the length of the forecastle or poop exceeds 0.25L, the scantlings of the two frames fitted at the after end of the forecastle or at the fore end of the poop are to be calculated by the formula used for 'tween deck frames located below the upper deck in way of the forecastle or poop.

2.7.2.13 The scantlings of four frames fitted at each end of the bridge are to be calculated by the formula used for 'tween deck frames located below the upper deck in way of the bridge.

2.7.2.14 The end connections of frames are to comply with the following:

(1) The scantlings of brackets connecting beams to upper ends of frames are to comply with 1.2.6 of this PART. Where decks are framed longitudinally, the brackets at the upper end of frames are to be extended to the nearest deck longitudinal and welded to it.
(2) The tank side brackets at the lower ends of main frames are to comply with the relevant requirements in Sections 5 and 6 of this Chapter.
(3) Where 'tween deck frames terminate at lower decks, their lower ends are to be bracketed. The scantlings of the brackets are to be the same as those at the upper end of 'tween deck frames. Where the 'tween deck frames and the frames thereunder are directly attached to the lower deck by welding, the lower end of the 'tween deck frames may not be bracketed.

2.7.3 Side stringers

2.7.3.1 Where side stringers are fitted to support the main frames and 'tween deck frames, the section modulus W and the moment of inertia I of the side stringers are not to be less than those obtained from the following formulae respectively:

$$W = 7.8hbl^2K \quad \text{cm}^3$$
$$I = 2.5Wl/K \quad \text{cm}^4$$

where: b — width of areas supported by the side stringers, in m;
h — vertical distance, in m, measured from the mid-span of side stringer to upper deck at side;
l — span of side stringers, in m;
K — material factor.

2.7.3.2 Brackets are to be fitted at the connection between side stringers and transverse bulkheads, and the requirements of 1.2.7 of this PART are to be complied with. Side stringers and web frames are to be so connected that an adequate continuity of the face plate or flange of side stringers is kept.

2.7.3.3 In transversely framed machinery spaces, side stringers are to be fitted to support main frames where the main frame span exceeds 6 m and their section modulus and moment of inertia are to comply with 2.7.3.1 of this Section and their web depth is not to be less than 2.5 times that of main frames.

2.7.3.4 In transversely framed machinery spaces, an arrangement of intercostal side stringers spaced generally 2.5 m apart may be accepted as an alternative to the side stringers specified in 2.7.3.3 of this Section and their web depth is to be the same as that of main frames, their web thickness t and sectional area A are to be respectively not less than those obtained from the following formulae:

$$t = 0.023L + 6 \quad \text{mm}$$
$$A = (0.14L + 1)K \quad \text{cm}^2$$

where: L — length of ship, in m, to be taken as not greater than 215 m in calculation;
K — material factor.

2.7.4 Transverse framing − web frames

2.7.4.1 The scantlings of web frames supporting side stringers are to be determined by direct calculation based on the assumptions that their both ends are rigidly fixed and that they are subject to concentrated loadings transmitted by side stringers (the considered pressure head being the distance from the mid-span of side stringers to upper deck at side, in m), with the permissible

bending stress being taken as 93.2/K, in N/mm² and the allowable shear stress as 83.4/K, in N/mm².

2.7.4.2 Where machinery spaces are situated aft and the ship's sides are transversely framed, web frames are to be fitted and spaced not more than five frame spaces apart in the machinery spaces, extending from the inner bottom to the upper deck.

2.7.4.3 In the areas of transversely framed machinery spaces, the scantlings of web frames supporting side stringers are to be determined in accordance with 2.7.4.1 of this Section.

2.7.4.4 In the areas of transversely framed machinery spaces, the section modulus W of web frames not supporting side stringers is not to be less than that obtained from the following formulas:

$$W = 5Shl^2K \quad \text{cm}^3 \quad \text{for spaces below the lowest deck}$$

$$W = 3.5Sdl\sqrt{D}\,K \quad \text{cm}^3 \quad \text{for 'tween decks}$$

where: S — spacing of web frames, in m;

h — vertical distance, in m, measured from the mid-span of web frame to upper deck at side;

l — span of web frame, in m;

d — draught, in m;

D — moulded depth, in m;

K — material factor.

2.7.4.5 In the areas of transversely framed machinery spaces, the web depth of web frames is not to be less than 2.5 times the depth of adjacent frames.

2.7.4.6 The end connections of web frames for transverse framing are to comply with the relevant provisions in 2.6.15 and 2.8.7.9 of this Chapter.

2.7.5 Side longitudinals

2.7.5.1 The section modulus W of side longitudinals below the upper deck (including bilge longitudinals) is not to be less than that obtained from the following formula:

$$W = \frac{8.5}{f} hsl^2 K \quad \text{cm}^3$$

where: s — spacing of longitudinals, in m;

l — span of longitudinals, in m;

f — factor, to be taken in accordance with following two formulae, and to be taken as not greater than 1.077:

$$f = 1.73 - F_d \frac{Z - Z_n}{D - Z_n} \quad \text{for } Z \geq Z_n$$

$$f = 1.73 - F_b \frac{Z_n - Z}{Z_n} \quad \text{for} < Z_n$$

h — design pressure head, to be taken from the following formula:

$$h = 0.26C + d - \frac{Z}{D}(0.06C + d)$$

Z_n — the height of horizontal neutral axis, from base line, of hull cross section, in m;

D — moulded depth, in m;

d — draft, in m;

C — coefficient, see 2.2.3.1 of this Chapter;

F_b, F_d — reduction factors, see 2.2.5.6 of this Chapter;

Z — height of longitudinals from base line, in m;

K — material factor.

2.7.5.2 Within the region between $0.2L$ from the F.P. and the forepeak bulkhead, the section modulus of side longitudinals below the upper deck is to be in accordance with 2.7.5.1 of this Section and also in accordance with 2.7.5.4 of this Section.

2.7.5.3 For machinery spaces situated aft, the section modulus of side longitudinals in the areas of the machinery spaces is to be in accordance with 2.7.5.1 of this Section and in addition, not less than 0.8 times that obtained from the formula in 2.7.5.5.

2.7.5.4 In the forepeak, the section modulus W of side longitudinals is to be taken as not less than that obtained from the following formula:

$$W = 7.5shl^2K \quad \text{cm}^3$$

where: s — spacing of longitudinals, in m;

h —vertical distance, in m, measured from the longitudinal to 3 m above the minimum bow height required by the load line, not less than the vertical distance from the longitudinal to upper deck at side;

l — span of longitudinals, in m, but taken as not less than 1.5 m;

K — material factor.

2.7.5.5 In the aft peak, the section modulus W of side longitudinals is to be taken as not less than that obtained from the following formula:

$$W = 8.5sl^2(h + 0.167D)K \quad \text{cm}^3$$

where:

s — spacing of longitudinals, in m;

l — span of longitudinals, in m, but taken as not less than 1.5 m;

h — vertical distance from the longitudinal to upper deck at side, in m, but not to be less than 3 m;

D — moulded depth, in m, but taken as not greater than 20 m;

K — material factor.

2.7.5.6 The section modulus of side longitudinals (including bilge longitudinals) need not be greater than that of bottom longitudinals with the same spacing.

2.7.5.7 The side longitudinals are to penetrate web frames and the intersections of longitudinal webs and frame webs are to be welded. Where a side longitudinal is cut in way of a transverse bulkhead, brackets are to be fitted at the connection between the longitudinal and the bulkhead, and the brackets are to comply with the relevant provisions in 1.2.6 of this PART.

2.7.6 Longitudinal framing — web frames

2.7.6.1 Where the side is framed longitudinally, web frames supporting side stringers are to be fitted in line with plate floors. In general, the spacing of web frames is not to be greater than 3.6 m for ships of 100 m in length or less, and not greater than $0.006L + 3.0$ m (L being length of ship) for ships more than 100 m in length. In the forepeak and aft peak, the spacing of web frames is not to be greater than 2.5 m for ships of 100 m in length or less, and not greater than 3.5 m for ships of 300 m or over in length. The intermediate values are to be obtained by interpolation.

2.7.6.2 Other than in machinery spaces and forepeak and aft peak, the section modulus W of web frames is not to be less than that obtained from the following formula:

$$W = 10Shl^2K \quad \text{cm}^3$$

where: S — spacing of web frames, in m;

h — vertical distance, in m, measured from the mid-span of the web frame to upper deck at side;

l — span of web frame, in m;

K — material factor.

2.7.6.3 In longitudinally framed machinery spaces, the section modulus W of web frames is not to be less than that obtained from the following formula:

$$W = 10Shl^2K \quad \text{cm}^3 \qquad \text{below the lowest deck}$$

$$W = 4.4Sdl\sqrt{D}\,K \quad \text{cm}^3 \qquad \text{in 'tween decks}$$

where: S — spacing of web frames, in m;

h — vertical distance, in m, measured from the mid-span of the web frame to upper deck at side;

l — span of web frame, in m;

d — draught, in m;

D — moulded depth, in m;

K — material factor.

The web depth of web frames is not to be less than 2.5 times that of the side longitudinal supported by it.

2.7.6.4 In the longitudinally framed forepeak, the section modulus W and the moment of inertia I of web frames are respectively not to be less than those obtained from the following formulae:

$$W = 14Shl^2K \quad \text{cm}^3$$

$$I = 2.5Wl/K \quad \text{cm}^4$$

where: S — spacing of web frames, in m;

h — vertical distance, in m, measured from the mid-span of the web frame to tank top or half of the vertical distance from the mid-span of the web frame to the top of overflow, whichever is the greater;

l — span of web frame, in m;

K — material factor.

Where struts are fitted, the web frames and struts are to comply with the relevant provisions of Section 5 of Chapter 6 of this PART.

2.7.6.5 In the longitudinally framed aft peak, the section modulus W is not to be less than that obtained from the following formula:

$$W = 10Shl^2K \quad \text{cm}^3$$

where: S — spacing of web frames, in m;

h — vertical distance, in m, measured from the mid-span of the web frame to upper deck at side;

l — span of web frame, in m;

K — material factor.

2.7.6.6 The end connections of web frames for longitudinal framing are to comply with the relevant provisions in Sections 6 and 8 of this Chapter and Chapter 5 of this PART.

Section 8 DECK FRAMING

2.8.1 General requirements

2.8.1.1 The design head h of decks is to be determined according to Table 2.8.1.1, and the corresponding design load p is to be calculated by the following formula:

$$p = \frac{9.81h}{\gamma} \quad \text{kPa}$$

where: h — design head, in m, see Table 2.8.1.1 of this Section;

γ — stowage rate, in m^3/t, taken as the standard rate of 1.39 m^3/t.

For decks in deep tanks, the relevant requirements in Section 13 of this Chapter are also to be complied with, and the corresponding design load P is to be calculated by the following formula:

$$p = 9.81\rho h \quad \text{kPa}$$

where: h — design head, in m, see Section 13 of this Chapter;

ρ — density of liquid, in t/m^3, to be taken not less than 1.025 t/m^3.

Design Heads of Decks Table 2.8.1.1

Name and location of deck	Design head h (m)	Permissible cargo load (kPa)
Weather decks (minimum sizes of structural members):		
Forward of 0.075L from F.P.	Primary members: $h_0 + 3$; Secondary members: 1.5 h_0	8.5
Between 0.075L and 0.15L from F.P.	Primary members: $h_0 + 2$; Secondary members: 1.25 h_0	8.5
Aft of 0.15L from F.P.	h_0	8.5
Weather decks (specified cargo load):		
Forward of 0.075L from F.P.	$0.49p + h_0 - 1.2$	p (> 8.5)
Between 0.075L and 0.15L from F.P.	$0.37p + h_0 - 1.2$	p (> 8.5)
Aft of 0.15L from F.P.	$0.14p + h_0 - 1.2$	p (> 8.5)
Cargo decks not exposed to weather	0.14p, but not to be less than mean height H, in m, of 'tween decks	Max (p, 7.06H)
Accommodation decks	1.2	—
Decks for stores	2.0	—
Decks for E.R. platform, workshop and stores	2.6	—
Superstructure decks:		
1st tier	0.90, increased for exposed portion $h_0 - 1.2$	—
2nd tier	0.60, increased for exposed portion $h_0 - 1.2$	—
3rd tier and above	0.45, increased for exposed portion $h_0 - 1.2$	—
Forecastle deck forward of 0.2L from F.P.	Same as weather decks in corresponding locations	—

Notes: ① h_0 in the Table is not to be less than that obtained from the following formula, but it is neither to be less than 1.2 m, nor greater than 1.5 m:

$$h_0 = 1.20 + \frac{2}{1000}\left(\frac{100 + 3L}{D - d} - 150\right) \quad \text{m}$$

where: L — length of ship, in m;
D — moulded depth, in m;
d — draught, in m.

② For ships less than 90 m in length, the design head of primary members within the areas of fore and aft ends of ships may be appropriately reduced, but not less than that of secondary members at the same location.

③ The superstructure deck is defined in 2.17.1.6 of this Chapter.

2.8.2 Deck beams

2.8.2.1 The section modulus W of deck beams is not to be less than that obtained from the following formula:

$$W = (C_1C_2Dd + C_3shl^2)K \quad \text{cm}^3$$

where: C_1 — coefficient, dependent on the number of decks (including bridge, poop decks and engine room platform) at the position of the beam under consideration: C_1 = 2.0 for 1st tier, C_1 = 1.33 for 2nd tier, C_1 = 1.05 for 3rd tier, C_1 = 0.93 for 4th tier and above, C_1 = 1.33 for forecastle deck;

C_2, C_3 — coefficients, see Table 2.8.2.1;

D — moulded depth, in m;

d — draught, in m;

s — spacing of beams, in m;

h — design head, in m, see 2.8.1.1 of this Section;

l — span of beam, in m, to be taken not less than 2 m;

K — material factor.

Coefficients C_2 and C_3 **Table 2.8.2.1**

Location of deck	C_2	C_3
Weather/strength deck or exposed forecastle deck forward of 0.075L from F.P.	0.8	0.54B
Weather/strength deck or exposed forecastle deck between 0.075L and 0.15L from F.P.	0.8	Beams connected to ship side: 0.36B
Weather/strength deck or exposed forecastle deck aft of 0.15L from F.P.	0.54	Beams elsewhere: 0.33B
Short bridge and poop deck where exposed to the weather	0.14	
Cargo decks and other decks (engine room, forepeak tank and aftpeak tank platforms)	0.40	4.0
Accommodation strength decks or lower decks	0.52	4.0

Note: B in the Table is the breadth of ship, in m.

2.8.2.2 The section modulus W of weather deck beams need not be greater than that obtained from the following formula:

$$W = Bshl^2K \quad \text{cm}^3$$

where: B — breadth of ship, in m, to be taken as not greater than 21.5 m;

s, h, l — see 2.8.2.1 of this Section;

K — material factor.

2.8.2.3 The web depth of deck beams is not to be less than 60 mm.

2.8.2.4 The connections between beams and frames are to comply with the requirements in 1.2.6 of this PART.

2.8.2.5 Beams are to pass through deck girders, and they are to be connected to the girder web by welding. Where beams are to be cut in way of the web of hatch side girders or deck girders, the beams are to be bracketed to the girders and the scantlings of brackets are to comply with the provisions in 1.2.6 of this PART. The brackets are to be extended to the face plate of deck girders.

2.8.3 Transverse framing — deck girders

2.8.3.1 For weather strength deck forward of 0.075*L* from F.P., the spacing of deck girders supporting beams is not to be greater than 3.6 m. For the upper and lower decks after the aft peak bulkhead, the spacing of deck girders supporting beams is not to be greater than 3 m.

2.8.3.2 The section modulus *W* of deck girders supporting beams is not to be less than that obtained from the following formula:

$$W = 4.75bhl^2K \quad \text{cm}^3$$

where: *b* — mean width, in m, of deck area supported by deck girders;

h — design head of deck, in m, see 2.8.1.1 of this Section;

l — span of deck girder, in m;

K — material factor.

2.8.3.3 Where deck girders arranged to support beams are subject to a concentrated load, their section modulus *W* is to be not less than that obtained from the following formula:

$$W = 0.102cPlK \quad \text{cm}^3$$

where: *P* — concentrated load, in kN;

l — span of deck girder, in m;

c — coefficient, to be obtained from Table 2.8.3.3 where *a* is the distance, in m, between the application point of concentrated load *P* and the farther one of two supports of the girder;

K — material factor.

Coefficient *c* **Table 2.8.3.3**

a/l	0.94	0.90	0.85	0.80	0.75	0.70	0.60	0.50
c	1.44	3.36	5.68	7.36	8.64	9.20	9.60	10

2.8.3.4 Where deck girders arranged to support beams are subject to two or three point loads, their section modulus *W* is to be determined by direct calculations assuming fixed ends and using an allowable bending stress of 124/*K*, in N/mm².

2.8.3.5 The section moment of inertia *I* of deck girders is not to be less than that obtained from the following formula:

$$I = 2Wl/K \quad \text{cm}^4$$

where: *W* — section modulus of deck girders required in this Section, in cm³;

l — span of deck girder, in m;

K — material factor.

2.8.3.6 The web depth of deck girders is not to be less than 1.6 times the depth of cut-outs for the passage of beams. The cut-outs in deck girders are to be designed to minimize the creation of stress concentration on the web. The web thickness of deck girders is not to be less than 1% of the web depth plus 4 mm.

2.8.3.7 Holes cut for the passage of pipes or cables in the web of deck girders are to have a depth not greater than 25% of that of the web and a width not exceeding 60% of the spacing of beams or

the web depth, whichever is the greater, otherwise compensation is required. Normally the compensation is achieved by fitting doublers, spigots or insert plates for strengthening, and the cross-sectional area of such strengthening pieces is to be not less than that lost from the web due to openings. The strength level of the material of strengthening pieces is not to be lower than that of the web material. The edges of holes are not to be less than 40% of the web depth from the face plate of girders. The edges of the holes are to be smooth and well rounded. The holes are not to be concentrated in the adjacent frame spaces. No holes are to be cut on the girder web within 200 mm from the toe of girder brackets.

2.8.3.8 The ends of deck girders are to be connected to transverse bulkheads in accordance with the relevant provisions in 1.2.7 of this PART. For deck girders contributing to the longitudinal strength, special attention is to be paid to the longitudinal structural continuity at transverse bulkheads.

2.8.4 Transverse framing — deck transverses

2.8.4.1 For deck transverses supporting deck girders, the scantlings are to be determined by direct calculations assuming fixed ends and the function for sustaining concentrated loads transmitted by deck girders and using an allowable bending stress of $124/K$, in N/mm².

2.8.4.2 The section moment of inertia I of deck transverses supporting deck girders is not to be less than that obtained from the following formula:

$$I = 2Wl/K \quad \text{cm}^4$$

where: W — section modulus of deck transverses, in cm³, obtained according to 2.8.4.1 of this Section;

l — span of deck transverse, in m;

K — material factor.

2.8.4.3 The thickness and cutouts of the web of deck transverses supporting deck girders are to comply with the provisions in 2.8.7.7 and 2.8.7.8 of this Section.

2.8.4.4 The connections between deck transverses supporting deck girders and frames or web frames or longitudinal bulkheads are to comply with the provisions of 2.8.7.9 of this Section.

2.8.5 Deck longitudinals

2.8.5.1 The section modulus W of weather/strength deck longitudinals is not to be less than the greater obtained from the following formulae:

$$W = c_1 shl^2 K \quad \text{cm}^3$$

$$W = (c_2 sh + c_3 sl^2 L^2 \times 10^{-4})K \quad \text{cm}^3$$

where:

s — spacing of longitudinals, in m;

h — design head of deck, in m, to be determined according to 2.8.1.1 of this Section, but outside the line of deck openings within $0.4L$ amidships:

$$h \geq \frac{22.6L}{1780 - L};$$

l — span of longitudinal, in m, to be taken as not less than 2 m;

c_1, c_2, c_3 — coefficients, to be determined according to Table 2.8.5.1;

L — length of ship, in m, L need not be taken as greater than 200 m;

K — material factor.

Coefficients c_1, c_2, c_3 **Table 2.8.5.1**

Item	Location of deck longitudianl	Region	c_1	c_2	c_3
1	Forward of 0.075L from F.P.		12.5	63.5	7.8
2	Between 0.075L ~ 0.15L from F.P.		12.5	57	7.2
3	At 0.15L from F.P.	Outside the line of openings	9	48.5	6.2
		Inside the line of openings	7.5	40	5.5
4	Between 0.15L ~ 0.3L from F.P.	Outside the line of openings	See note		
		Inside the line of openings	7.5	40	5.5
5	0.4L amidships	Outside the line of openings	10.5	–	–
		Inside the line of openings	7.5	40	5.5
6	Between 0.075L ~ 0.3L from A.P.	Outside the line of openings	See note		
		Inside the line of openings	7.5	40	5.5
7	Aft of 0.07L from A.P.		7.5	40	5.5

Note: The section modulus W of deck longitudinals in way of the region may be determined after tapering the section moduli of amidships and end deck longitudinals.

2.8.5.2 The section modulus W of cargo deck longitudinals (including longitudinals of decks/platforms within the engine room, fore and aft peaks) is not to be less than the following:

$$W = (2.5shl^2 + 0.6sL)K \quad \text{cm}^3 \text{ for } L \geq 90 \text{ m}$$

$$W = 5shl^2K \quad \text{cm}^3 \text{ for } L < 90 \text{ m}$$

where: s, h, l, L, K — see those in 2.8.5.1 of this Section.

2.8.5.3 The section modulus W of accommodation and superstructure deck longitudinals is not to be less than the following:

$$W = (2.5shl^2 + 0.52sL)K \quad \text{cm}^3 \text{ for } L \geq 90 \text{ m}$$

$$W = 4.4shl^2K \quad \text{cm}^3 \text{ for } L < 90 \text{ m}$$

where: s, h, l, L, K — see those in 2.8.5.1 of this Section.

2.8.5.4 The web depth of deck longitudinals is in no case to be less than 60 mm.

2.8.5.5 The deck longitudinals outside the line of deck openings are to pass through deck transverses and to be connected to the deck transverse webs by welding. Where the deck longitudinals are cut in way of the web plates of hatch end beams or deck transverses (only for those inside the line of deck openings or at the ship's ends), brackets are to be fitted at the connection between deck longitudinals and hatch end beams or deck transverses and the scantlings of the brackets are to comply with the relevant provisions in 1.2.6 of this PART. The brackets are to be extended to the face plate of hatch end beams or deck transverses along the web plates of hatch end beams or deck transverses.

2.8.5.6 Where deck longitudinals are cut in way of transverse bulkheads, brackets are to be fitted at the connection between deck longitudinals and transverse bulkheads and the scantlings of the brackets are to comply with the relevant provisions in 1.2.6 of this PART. Where the ship's length exceeds 200 m or higher tensile steel is adopted, the deck longitudinals outside the line of deck openings are to be continuous through the transverse bulkheads, but alternative arrangements may be considered.

2.8.5.7 The deck longitudinals outside the line of deck openings are not to be terminated at the same transverse section and their ends are to be suitably shifted from one another. These ends are to extend to the adjacent transverse members.

2.8.6 Longitudinal framing — deck girders

2.8.6.1 For deck girders supporting deck transverses, the scantlings are to be determined by direct calculations assuming fixed ends and the function for sustaining concentrated loads transmitted by deck transverses and using an allowable bending stress of $124/K$, in N/mm^2.

2.8.6.2 The section moment of inertia I of deck girders supporting deck transverses is not to be less than that obtained from the following formula:

$$I = 2Wl/K \quad \text{cm}^4$$

where: W — section modulus of deck girders, in cm^3, obtained according to 2.8.6.1 of this Section;

l — span of deck girder, in m;

K — material factor.

2.8.6.3 The thickness and cutouts of the web of deck girders supporting deck transverses are to comply with the relevant provisions in 2.8.3.6 and 2.8.3.7 of this Section respectively.

2.8.6.4 The connections between deck girders supporting deck transverses and transverse bulkheads are to comply with the relevant provisions of 2.8.3.8 of this Section.

2.8.7 Longitudinal framing — deck transverses

2.8.7.1 Where the deck is framed longitudinally, deck transverses supporting the deck longitudinals are to be fitted in line with plate floors. In general, the spacing of deck transverses is not to be greater than 3.6 m for ships of 100 m in length or less and not greater than $0.006L + 3.0$ m (L being length of ship) for ships more than 100 m in length, In the forepeak and aft peak, the spacing of deck transverses is not to be greater than 2.5 m for ships of 100 m in length or less and not greater than 3.5 m for ships of 300 m or over in length. The intermediate values are to be obtained by interpolation.

2.8.7.2 In the machinery spaces and aft peak tank, deck transverses supporting deck longitudinals are to be fitted in frames spaces of web frames.

2.8.7.3 The section modulus W of deck transverses supporting deck longitudinals is not to be less than that obtained from the following formula:

$$W = 5Shl^2K \quad \text{cm}^3$$

where: S — spacing of deck transverses, in m;

h — design head of deck, in m, to be determined according to 2.8.1.1 of this Section;

l — span of deck transverses, in m;

K — material factor.

2.8.7.4 The section modulus of deck transverses in single deck ships is to be 15% greater than that obtained from the formula in 2.8.7.3 of this Section.

2.8.7.5 Where the deck transverses supporting deck longitudinals are subject to concentrated loads, their increased section modulus may be determined by calculations in accordance with the requirements for deck girders in 2.8.3.3 or 2.8.3.4 of this Section.

2.8.7.6 The section moment of inertia I of deck transverses supporting deck longitudinals is not to be less than that obtained from the following formula:

$$I = 2Wl/K \quad \text{cm}^4$$

where: W — section modulus of deck transverses, in m³, as required in this Section;

l — span of deck transverses, in m;

K — material factor.

2.8.7.7 The web depth of deck transverses is not to be less than 1.6 times the depth of cut-outs for the passage of deck longitudinals. The cutouts in deck transverses are to be designed to minimize the creation of stress concentration on the web. The web thickness of deck transverses is not to be less than 1% of the web depth plus 4 mm.

2.8.7.8 Holes cut for the passage of pipes or cables in the web of deck transverses are to have a depth not greater than 25% of that of the web and a width not exceeding 60% of the spacing of deck longitudinals or the web depth, whichever is the greater, otherwise compensation is required. Normally the compensation is achieved by fitting doublers, spigots or insert plates for strengthening, and the cross-sectional area of such strengthening pieces is to be not less than that lost from the web due to openings. The strength level of the material of strengthening pieces is not to be lower than that of the web material. The edges of holes are not to be less than 40% of the web depth from the face plate of deck transverses. The edges of the holes are to be smooth and well rounded. The holes are not to be concentrated in the spacings of adjacent longitudinals. No holes are to be cut on the web of deck transverses within 200 mm from the bracket toe of deck transverses.

2.8.7.9 The ends of deck transverses are to be bracketed to frames or web frames or longitudinal bulkheads, and the scantlings of brackets are to comply with the relevant provisions in 1.2.7 of this PART. Where the connection between deck transverses and web frames or longitudinal bulkhead vertical webs is designed as an integral structure, a ring system is generally to be formed and connecting brackets are to have the form of an circular arc with a radius generally not less than the web depth of deck transverses or web frames or longitudinal bulkhead vertical webs, whichever is the smallest. The brackets are to be provided with a face plate to connect the face plate of deck transverses and that of web frames or longitudinal bulkhead vertical webs, and the scantlings of the face plate are to be the same as those of the face plate of deck transverses.

2.8.8 Deck hatch side girders

2.8.8.1 Where weather deck hatch side girders (including weather deck hatch side coamings) act as deck girders and are supported at both ends of the hatchway, their section modulus W and section moment of inertia I are not to be less than those obtained from the following formulae respectively:

$$W = 7hbl^2K \quad \text{cm}^3$$

$$I = 2.6Wl/K \quad \text{cm}^4$$

where: h — design head of deck, in m, see 2.8.1.1 of this Section;

b — mean width, in m, of deck area supported by deck hatch side girders;

l — span of deck hatch side girder, in m;

K — material factor.

2.8.8.2 The section modulus W and section moment of inertia I of 'tween deck hatch side girders are not to be less than those obtained from the following formulae respectively:

$$W = 5.2hbl^2K \quad \text{cm}^3$$

$$I = 2Wl/K \quad \text{cm}^4$$

where: h — design head of deck, in m, see 2.8.1.1 of this Section;

b — mean widdth, in m, of deck area supported by 'tween deck hatch side girders;

l — span of 'tween deck hatch side girder, in m;

K — material factor.

2.8.8.3 Where 'tween deck hatch side girders are subject to concentrated loads, the section modulus is to be increased to 1.1 times that obtained according to 2.8.3.3 or 2.8.3.4 of this Section.

2.8.8.4 The depth of the web of deck hatch side girders below deck is not to be less than that of the beam web to which it is connected.

2.8.8.5 The thickness of the web of deck hatch side girders is not to be less than 1% of its depth plus 4 mm. The thickness and structure of hatch coamings are to comply with the requirements of 2.20.3.2 of this Chapter.

2.8.8.6 In the calculation of the section modulus and section moment of inertia of deck hatch side girders (including hatch coamings), the upper edge of the horizontal face plate (excluding holes in the face plate) of hatch coamings may be included; or only the upper edge of the horizontal stiffener is to be included if no horizontal face plate is fitted.

2.8.8.7 A gradual transition in depth is to be made for the extension of deck hatch side girders.

2.8.8.8 Where the deck is framed longitudinally, deck hatch side girders are to be bracketed to deck transverses. Where the web depth of deck hatch side girders below deck is the same as that of deck transverses, the girders and transverses are to be directly connected. Where the spacing of deck transverses is greater than two frame spaces, an additional tripping bracket is to be fitted between the transverses. This tripping bracket is to extend to the face plate of the deck hatch side girder and to the adjacent deck longitudinals. The thickness of the bracket is to be the same as that of the web plate of adjacent deck transverses, and the flange or face plate of the bracket is to comply with the provisions in 1.2.6.6 of this PART.

2.8.8.9 Where the deck is framed transversely, a bracket is to be fitted at the connection between each beam and deck hatch side girders. These brackets are to extend to the face plate of deck hatch side girders, and the scantlings of the brackets are to comply with the provisions in 1.2.6 of this PART.

2.8.9 Hatch end beams

2.8.9.1 Hatch end beams are to be fitted in accordance with the following requirements:

(1) Where a pillar complying with the requirements of Section 10 of this Chapter is fitted at each corner of the hatchway (i.e. hatch end beams do not support hatch side girders), the section modulus of hatch end beams is to meet the requirements of 2.8.2.1 of this Section, but in this case, s in the formula is to be the actual width of deck area supported by hatch end beams.

(2) Where hatch end beams support the full load of hatch side girders, pillars are fitted below the beams at the longitudinal centerline of deck and deck longitudinal girders or longitudinal bulkheads are also fitted at the longitudinal centerline, hatch end beams are to be continuous within the breadth of ship and their section modulus W and section moment of inertia I are not to be less than those obtained from the following formulae respectively:

$$W = 4.6chAlK \quad \text{cm}^3$$

$$I = 3Wl/K \quad \text{cm}^4$$

where: l — span of hatch end beams, in m;

K — material factor;

A — load area, in m^2, to be determined according to the following conditions:

① Where the deck is framed longitudinally and the extension of hatch side girders supports one or more deck transverses, see Figure 2.8.9.1(1):

$$A = F_1 + 2F_3 + F_4 + F_5$$

② Where the deck is framed longitudinally and the extension of hatch side girders does not support any deck transverse, see Figure 2.8.9.1(2):

$$A = F_1 + F_2 + F_3$$

③ Where the deck is framed transversely without additional girders, see Figure 2.8.9.1(3):

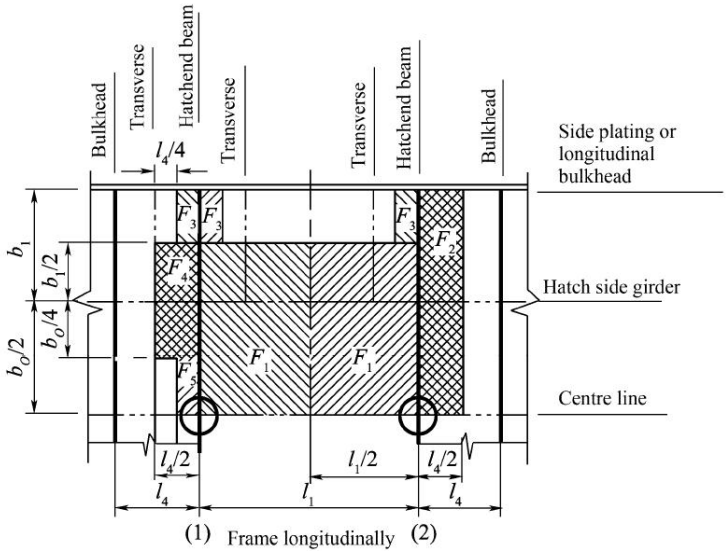
$$A = F_1 + F_4$$

④ Where the deck is framed transversely and with fitted with additional girders, see Figure 2.8.9.1(4):

$$A = F_1 + F_4;$$

h — design head of deck, in m, see 2.8.1.1 of this Section;

c — coefficient, to be taken according to the distance a between the hatch side girder and the longitudinal centreline: c = 1.6 for a ≥ l/2 (l being span of hatch end beams), c = 1.5 for a ≤ l/3, and c is to be obtained by interpolation for l/3 < a < l/2.



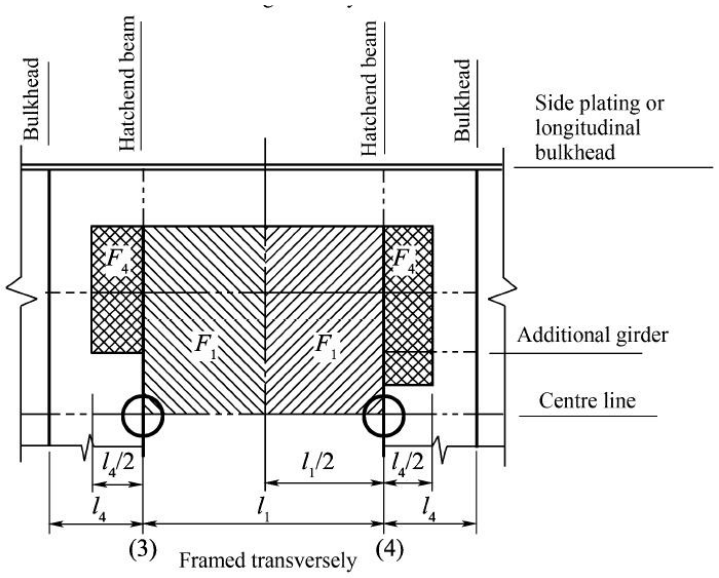


Figure 2.8.9.1

2.8.9.2 The connections between hatch end beams and frames or web frames or longitudinal bulkheads are to comply with the requirements of 2.8.7.9 of this Section.

Section 9 CANTILEVERS

2.9.1 General requirements

2.9.1.1 Cantilevers covered by this Section are the deck transverses extending from ship side to the deck hatch side girders supported by them. The structural configuration of cantilevers and their supporting frames is as shown in Figure 2.9.1.1.

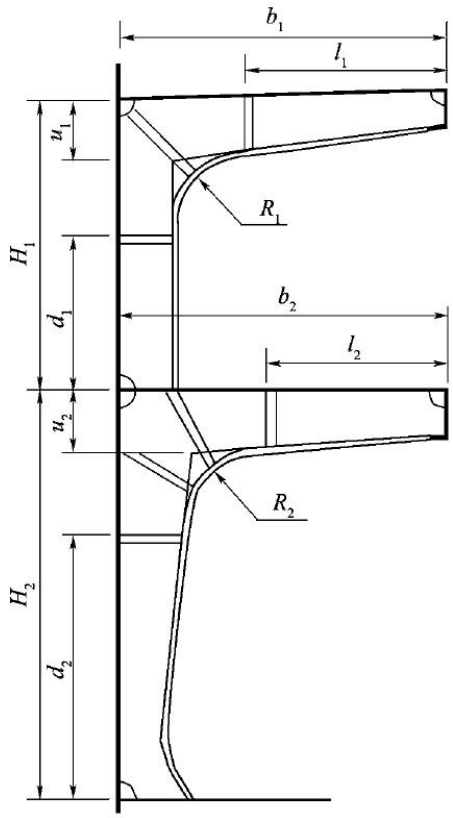

Figure 2.9.1.1

2.9.1.2 The considered sections of the cantilever and its supporting frame are to be the corresponding sections at the toe of the connecting bracket (i.e. at the tangential point of the arc of the bracket).

2.9.1.3 The requirements of this Section are applicable to ships having cantilevers approximately equally arranged, hatch side girders supported by cantilevers and uniform loading on decks and hatch covers.

2.9.2 Cantilevers

2.9.2.1 The section modulus W_i of the considered section of cantilevers is not to be less than the respective values given below:

(1) Where cantilevers are not supported by hatch side girders:

$$W_i = 30.6Sl_i(l_i\, h_1 + b_0\, h_2)K \quad \text{cm}^3$$

where: S — load width of cantilever, in m;

l_i — span of cantilever, in m;

b_0 — width of hatch, in m;

h_1 — design head of deck outside the line of hatch openings, in m, see 2.8.1.1 of this Chapter;

h_2 — design head of deck or hatch cover inside the line of hatch openings, in m, see 2.8.1.1 or 2.20.2 of this Chapter;

K — material factor.

(2) Where both ends of hatch side girders are fitted with the hatch end beams complying with the requirements of 2.8.9 of this Chapter and cantilevers are partially supported by hatch side girders:

$$W_i = W_0 - G \quad \text{cm}^3$$

where: $W_0 = 30.6\, S\, l_i(l_i\, h_1 + b_0\, h_2)K$ cm^3

where: S, l_i, b_0, h_1, h_2 — see (1) above;

$$G = \frac{8l_i}{(n+1)l_h}(W_h + W_P) \quad \text{cm}^3$$

where: W_h — section modulus of the hatch side girder derived from 2.8.8.1 or 2.8.8.2 of this Chapter, in cm³, and the span of cantilevers taken as the spacing of cantilevers;

W_p — section modulus of deck girders on the extension line of hatch side girders, in cm³, derived from 2.8.3 of this Chapter, and W_p is to be taken not greater than W_h;

n — number of cantilevers between hatch end beams;

l_h — length of hatch, in m;

l_i — span of cantilevers, in m.

(3) Where both ends of hatch side girders are supported by transverse bulkheads and cantilevers are partially supported by hatch side girders:

$$W_i = \frac{n+1}{n}\left[0.5\left(1+\frac{1}{Q}\right)W_o - QG - (1-Q)E\right] \quad \text{cm}^3$$

where: W_o, G, n — see (2) above;

$$Q = \frac{l_h}{l_b};$$

where: l_h, l_b — See Figure 2.9.2.1(1) of this Section;

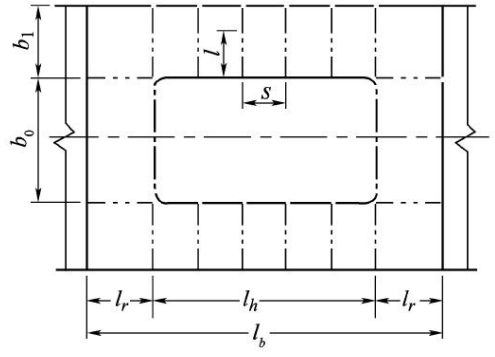
$E = \frac{4}{n+1}(W_1 + W_2)$ in cm³ for hatch end beams the midpoint of which is not supported by pillars, etc., or

$E = \frac{4}{n+1}\left[(W_1 + W_2) + \frac{2l_i}{b_o}(W_2 + W_3)\right]$ in cm³, for hatch end beams the midpoint of which is supported by pillars or bulkheads;

where: W_1, W_2 and W_3 are section moduli of hatch end beams, in cm³, as shown in Figure 2.9.2.1(2), W_2 is to be taken as the lesser of the section moduli of hatch end beams at both sides of the line of hatch openings;

l_i, b_0 — see Figure 2.9.2.1(1) of this Section.

And in addition, the section modulus W_i of the cantilever is not to be less than that obtained from (2) above.



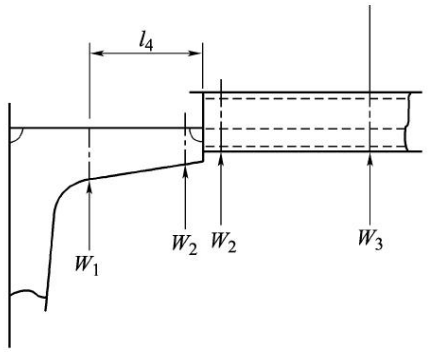


Figure 2.9.2.1(1) **Figure 2.9.2.1(2)**

(4) Where loading is concentrated at hatch side girders and cantilevers are partially supported by hatch side girders:

$$W_i = W'_0 - \frac{3.5 l_i}{S} W_h \quad \text{cm}^3$$

where: W'_0 — section modulus, in cm³, of the cantilever when subjected to concentrated loading and uniform loading, with no support from hatch side girders. In the calculation, the cantilever is to be assumed fixed at one end, and the allowable bending stress is to be taken as 115.2 N/mm²;

l_i, S, W_h — see (1) and (2) above.

And in addition, the section modulus W_i of the cantilever is not to be less than those obtained from (2) and (3) above.

2.9.2.2 The moment of inertia I of the cantilever at the section under consideration is not to be less than that obtained from the following formula:

$$I = 9\ W_i l_i / K_i \quad \text{cm}^4$$

where: W_i — section modulus of cantilevers, in cm³, derived from the formula in 2.9.2.1 of this Section;

l_i — span of cantilevers, in m;

K_i — material factor.

2.9.2.3 The net sectional area A_x of the cantilever web is not to be less than that obtained from the following formula:

$$A_x = 0.43\ S\left(2 h_i X + b_o h_2 + \frac{0.283}{S} P_c\right)\frac{W_i}{W_o} \quad \text{cm}^2$$

where: S, b_0, h_1, h_2 — see 2.9.2.1(1) of this Section;

X — distance, in m, between the section of cantilever under consideration and the hatch side girder;

W_o — see 2.9.2.1(2) of this Section, in cm³;

W_i — section modulus of cantilevers, in cm³, as required in 2.9.2.1 of this Section;

P_c — concentrated loading, in kN, applied on the hatch side girder for calculation in accordance with 2.9.2.1(4) of this Section. P_c = 0, if no concentrated loading is applied.

2.9.3 Supporting frames

2.9.3.1 The section modulus W_{fi} at the considered section of supporting frames is not to be less than that obtained from the following formula:

$$W_{fi} = \frac{d_i}{H_i}\left[\frac{b_i}{l_i} W_i - W_{f(i-1)}\right] \quad \text{cm}^3$$

where: d_i, H_i, b_i, l_i — see Figure 2.9.1.1 of this Section;

$W_{f(i-1)}$ — section modulus of supporting frames of the cantilevers on the $i-1$ tier deck, in cm³, and $W_{f(i-1)} = 0$ for the upper deck;

W_i — section modulus of cantilevers, in cm³, as required in 2.9.2.1 of this Section;

i — tier sign of decks, i = 1 for upper deck, i = 2 for 2nd tier deck and so on.

2.9.3.2 The scantlings of the supporting frames of the lower deck are, in general, not to be less than those of the supporting frames of the 'tween deck above.

2.9.4 Structural requirements

2.9.4.1 Cantilevers and supporting frames are to be connected by brackets. The radius of the arc of the bracket is not to be less than u_i. The sectional area of the face plate and the web thickness of the bracket are not to be less than those of the larger one of connected members. Tripping brackets are to be fitted at the toes of the brackets (i.e. in way of the considered section of the cantilever and supporting frame), and an adequate number of stiffeners is to be fitted to the web connecting the bracket. See Figure 2.9.1.1.

2.9.4.2 Where the deck is framed longitudinally, cantilevers are to be provided with tripping brackets in accordance with the requirements of 1.2.5.4 of this PART; where the deck is framed transversely, the tripping brackets of cantilevers are to be generally spaced 3 m apart.

2.9.4.3 The minimum thickness of the web plate of cantilevers and supporting frames is not to be less than 1% of the web depth plus 4.5 mm. Where the web depth is greater than 700 mm, vertical stiffeners are to be fitted and spaced not greater than 1.5 times the web depth apart.

2.9.4.4 The web depth and the sectional area of face plates of cantilevers and supporting frames may be gradually tapered from the considered section to the ends, but the minimum web depth at ends is not to be less than 50% of the web depth at the considered section, and the sectional area of face plates at ends is not to be less than 60% of that at the considered section. Longitudinals passing through cantilevers and supporting frames are, in addition, to comply with the relevant requirements of 2.8.7.7 of this Chapter.

2.9.4.5 The effective area of the attached plating of cantilevers and supporting frames is to be calculated according to the requirements of 1.2.2.1 of this PART.

2.9.4.6 Where cantilevers and supporting frames consist of two or three combined members having a T-shaped cross section, they are to be regarded as a single cantilever, and the section modulus of such combined cantilevers is to be determined according to 2.9.2.1 of this Section, and the individual modulus of each cantilever is then determined by dividing this modulus by the actual number of cantilevers.

2.9.4.7 The supporting frames in holds are to be securely connected to the inner bottom by brackets. Plate floors or other stiffening arrangements are to be provided in the double bottom in line with cantilevers and supporting frames.

2.9.4.8 The web depth of hatch side girders below the deck is in general not to be less than that of the web plate at the end of cantilevers. Cantilevers and hatch side girders are to be securely connected with each other.

Section 10 PILLARS

2.10.1 Load supported by pillars

2.10.1.1 The load P supported by the pillar is to be calculated according to the following formula:

$$P = 7.06abh + P_0 \quad \text{kN}$$

where: a — length of deck area supported by the pillar, in m, as shown in Figure 2.10.1.1;

b — mean width of deck area supported by the pillar, in m, as shown in Figure 2.10.1.1;

h — design head of the deck supported by the pillar, in m, see 2.8.1.1 of this Chapter;

P_0 — load transmitted from the pillar above, in kN.

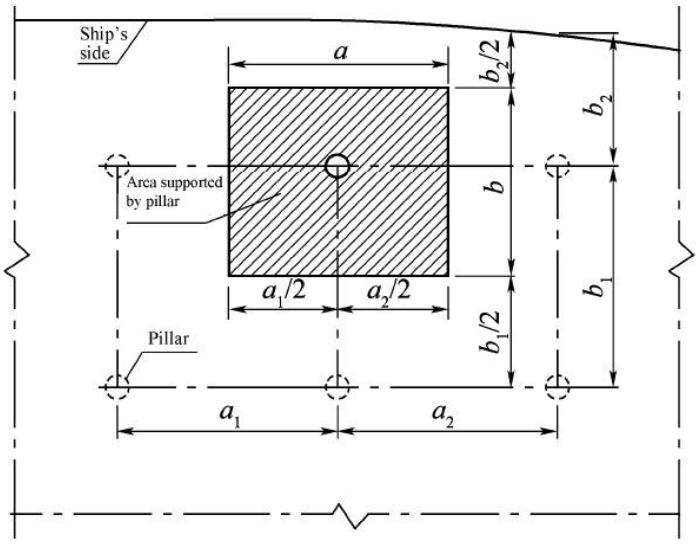

Figure 2.10.1.1

2.10.2 Cross-sectional area of pillars

2.10.2.1 The cross-section area A of pillars is not to be less than that obtained from the following formula:

$$A = \frac{KP}{12.26 - 5.10\dfrac{l}{r\sqrt{K}}} \quad \text{cm}^2$$

where: P — see 2.10.1.1 of this Section;

l — the effective length of pillars, in m, to be taken as 0.8 times the whole length of pillars;

r — minimum radius of gyration of the cross section of pillars, in cm;

K — material factor, but it is not to be taken less than 0.72.

2.10.3 Minimum wall thickness of pillars

2.10.3.1 The wall thickness t of tubular pillars is not to be less than the following:

$$t = \frac{P}{0.392d_p - 4.9l} \quad \text{mm}$$

$$t = \frac{d_p}{40} \quad \text{mm}$$

where: P — see 2.10.1.1 of this Section;

l — see 2.10.2.1 of this Section;

d_p — mean diameter of tubular pillars, in mm.

The minimum wall thickness of tubular pillars is to be 5 mm for ship's length $L < 60$ m; 6 mm for 60 m $\leq L <$ 90 m and 7 mm for $L \geq 90$ m.

2.10.3.2 The built or rolled-section pillars are to comply with the following requirements:

(1) The wall thickness t of hollow rectangular pillars or the web thickness t of I-shaped or channel-section pillars is not to be less than the lesser of the following:

$$t = \frac{br}{60l} \quad \text{mm}$$

$$t = \frac{b}{55} \quad \text{mm}$$

where: b — length of hollow rectangular pillars or web depth of I-shaped or channel-section pillars, in mm;

l, r — see 2.10.2.1 of this Section.

The minimum wall thickness of hollow rectangular pillars or the minimum web thickness of I-shaped or channel-section pillars is not to be less than 5 mm for ship's length $L < 60$ m, 6 mm for 60 m $\leq L <$ 90 m and 7 mm for $L \geq 90$ m.

(2) The side thickness t of angular pillars and the face plate thickness t of channel-section pillars are not to be less than the lesser of the following:

$$t = \frac{br}{20l} \quad \text{mm}$$

$$t = \frac{b}{18} \quad \text{mm}$$

where: b — side length of angular pillars or face plate breadth of channel-section pillars, in mm;

l, r — same as defined in 2.10.2.1 of this Section.

(3) The thickness t of face plate of I-shaped pillars is not to be less than the lesser of the following:

$$t = \frac{br}{40l} \quad \text{mm}$$

$$t = \frac{b}{36} \quad \text{mm}$$

where: b — breadth of face plate of I-shaped pillars, in mm;

l, r — same as defined in 2.10.2.1 of this Section.

2.10.4 Strengthening of structures at heads and heels of pillars

2.10.4.1 The structures at the heads and heels of pillars are to be so arranged that loads are reasonably supported and transmitted. Tubular and hollow rectangular pillars are to be attached at their heads to plates supported by efficient brackets. Longitudinal and transverse brackets are to be fitted at the heads and heels of the built or rolled-section pillars. Doubler or insert plates are to be fitted below pillars.

2.10.4.2 Pillars are to be fitted on plate floors or girders, and these plate floors or girders are to be fitted with vertical stiffeners. Widely spaced pillars are to be fitted at the intersection of plate floors and girders and if they are not fitted at the intersection, partial floors or girders are to be fitted below such pillars. Manholes are not to be cut in the floors and girders below pillars.

2.10.4.3 Where pillars are fitted on a shaft tunnel or any weak framing, structural strengthening is required in way of the pillars.

2.10.4.4 For pillars fitted inside ballast tanks or other tanks, attention is to be given to the effects of possible tensions.

2.10.4.5 Tubular or hollow rectangular pillars are not to be used inside oil tanks.

Section 11 NON-WATERTIGHT PILLAR BULKHEADS

2.11.1 General requirements

2.11.1.1 The minimum thickness of bulkhead plating is to be 7 mm in lower holds and 6 mm in 'tween decks and where the ship's length is less than 90 m, the minimum thickness is to be 5 mm.

2.11.1.2 The maximum spacing of bulkhead stiffeners is to be 1,500 mm.

2.11.1.3 The sectional area A of bulkhead stiffeners (including attached plating not exceeding 600 mm in width), which support beams, longitudinals, girders, transverses, etc., is not to be less than the following:

$$A = \frac{KP}{12.26 - 5.1\frac{l}{r\sqrt{K}}} \quad \text{cm}^2 \quad \text{for } \frac{s}{t} \leq 80$$

$$A = \frac{KP}{4.86 - 1.475\frac{l}{r\sqrt{K}}} \quad \text{cm}^2 \quad \text{for } \frac{s}{t} \geq 120$$

A is to be obtained by interpolation for $80 < \frac{s}{t} < 120$

where: P, r — see 2.10.2.1 of this Chapter;

l — span of stiffeners, in m;

s — spacing of stiffeners, in mm;

t — thickness of bulkhead plating, in mm;

K — material factor, to be taken not less than 0.72.

2.11.1.4 The minimum web depth of stiffeners is to be 150 mm in lower holds and 100 mm in 'tween decks and where the ship's length is less than 90 m, the minimum depth is to be 100 mm and 75 mm respectively.

Section 12 WATERTIGHT BULKHEADS

2.12.1 General requirements

2.12.1.1 Watertight bulkheads are to comply with the requirements of this Section and in addition, the relevant requirements of Section 12, Chapter 1 of this PART.

2.12.1.2 The total number of transverse watertight bulkheads is, in general, not to be less than that given in Table 2.12.1.2. For ships over 190 m in length, this number is to be determined by direct calculation.

Total Number of Transverse Watertight Bulkheads **Table 2.12.1.2**

Ship's length / Ship type	$L \leq 60$	$60 < L \leq 85$	$85 < L \leq 105$	$105 < L \leq 125$	$125 < L \leq 145$	$145 < L \leq 165$	$165 < L \leq 190$

Machinery amidships	4	4	5	6	7	8	9
Machinery aft	3	4	5	6	6	7	8

2.12.1.3 Transverse watertight bulkheads are to be fitted in accordance with the following requirements:

(1) All transverse watertight bulkheads are to extend to the bulkhead deck, except collision bulkheads and after peak bulkheads.

(2) The bulkheads in the holds are to be spaced at uniform intervals. Where the length of a hold is greater than 0.15*L* or 30 m, whichever is the greagter, transverse structures are to be strengthened and relevant supporting documents are to be submitted.

(3) Where it is impracticable for the arrangement of transverse watertight bulkheads to comply with Table 2.12.1.2 due to the requirements of a special trade, one or more of these bulkheads may be dispensed with, subject to suitable structural compensation and demonstration by direct calculation that the transverse strength is adequate.

2.12.1.4 Where the bulkheads form the boundaries of deep tanks, the bulkhead structures are also to satisfy the requirements of Section 13 of this Chapter for the deep tank bulkheads.

2.12.1.5 The bulkheads may be of the plane, symmetrically corrugated or double-plated type.

2.12.2 Collision bulkhead

2.12.2.1 For the calculation of structural members of collision bulkheads, the value h is to be 1.25 times the height required accordingly.

2.12.3 Plane bulkhead plating

2.12.3.1 The thickness t of the plane watertight bulkhead plating is not to be less than that obtained from the following formula, nor less than 5.5 mm:

$$t = 4s\sqrt{hK} \quad \text{mm}$$

where: s — spacing of stiffeners, in m;

h — vertical distance, in m, measured from the lower edge of the plate in a strake to the bulkhead deck at side, to be taken as not less than 2.5 m;

K — material factor.

2.12.3.2 The thickness of bulkhead plating in way of bilges or bilge wells is to be increased by 2.5 mm, and the thickness of bulkhead plating in way of the passage of the stern tube is to be doubled.

2.12.3.3 The lowest strake of bulkheads is not to be less than 900 mm in height measured from the inner bottom, or from the bottom in the case of single bottom. Where a double bottom is provided on one side and a single bottom on the other side of the bulkhead, the lowest strake is to extend at least 300 mm above the flat portion of the double bottom.

2.12.3.4 Where the difference in thickness between the bulkhead and the web of longitudinal girders attached to the bulkhead is too great, the thickness of bulkhead plating in way is to be increased.

2.12.4 Plane bulkhead stiffeners

2.12.4.1 The section modulus W of bulkhead stiffeners is not to be less than that obtained from the following formula:

$$W = Cshl^2K \quad \text{cm}^3$$

where: s — spacing of stiffeners, in m;

h — vertical distance, in m, measured from the mid-span of stiffeners to the bulkhead deck at side, but not to be taken as less than 2 m;

l — span of stiffener, in m;

C — coefficients, to be taken as follows:

$C = 6$, for stiffeners unattached at both ends, or directly attached to unstiffened plating;

$C = 3$, for stiffeners bracketed at ends; stiffeners directly lapped to longitudinal members at ends; stiffeners directly connected to longitudinally framed deck plating (inner bottom) at ends, and the stiffeners are in line with the webs of longitudinals; stiffeners directly connected to deck plating or girder web at ends, provided that the other side of the deck plating or girder is connected to an adjacent member having at least the same cross section as and in line with the said stiffener;

K — material factor.

2.12.4.2 Where a transverse bulkhead supports deck girders, bulkhead stiffeners are to be fitted in way of the deck girders. The sectional area of these stiffeners together with attached plating is also to comply with the requirements of Section 11 of this Chapter for non-watertight pillar bulkheads.

2.12.4.3 The scantlings of end brackets of bulkhead stiffeners are to comply with the provisions in 1.2.6 of this PART. Stiffeners unattached at ends are applicable only in the upper 'tween deck spaces.

2.12.4.4 The brackets at the ends of stiffeners are to be extended and efficiently welded to the beams or floors adjacent to the bulkhead respectively. Where the deck or bottom is framed longitudinally and where the brackets at ends of stiffeners are not in line with longitudinals, stiffening bars are to be fitted between the ends of brackets and longitudinals.

2.12.4.5 The minimum web depth of stiffeners is to meet the requirements of 2.11.1.4 of this Chapter, and the thickness t of the web is to meet the following requirements:

For rolled or combined stiffeners with flange or face plate: $t \geq \dfrac{d_w}{60\sqrt{K}}$ mm

For flat bar stiffeners: $t \geq \dfrac{d_w}{18\sqrt{K}}$ mm

where: d_w — depth of stiffener webs, in mm;

K — material factor.

2.12.5 Bulkheads with symmetrical corrugations

2.12.5.1 Symbols for the dimensions of corrugations are as shown in Figure 1.2.4.3, Chapter 1 of this PART.

2.12.5.2 Dimensions of corrugations are to comply with the following requirements:

(1) The section modulus W of a corrugation over a spacing is not to be less than that obtained from the following formula:

$$W = Cshl^2K \quad cm^3$$

where: l — span of corrugation, in m;

h — vertical distance, in m, measured from the mid-span of the corrugation to the bulkhead deck at side, but not to be taken as less than 2 m;

s — spacing of corrugations, in m;

C — coefficient, to be taken according to the end fixity as specified in Table 2.12.5.2;

K — material factor.

(2) The angle α between web and flange of corrugations is not to be less than 40°.

(3) Where the span of corrugation exceeds 15 m, a diaphragm plate is to be arranged near the mid-span or equivalent measures for strengthening are to be taken.

Value of Coefficient *C* **Table 2.12.5.2**

Upper end / Lower end	Directly connected to deck	As shown in Figure 2.12.5.2(2) or (3)
As shown in Figure 2.12.5.2(1) or (2) or (3)	5.04	3.84

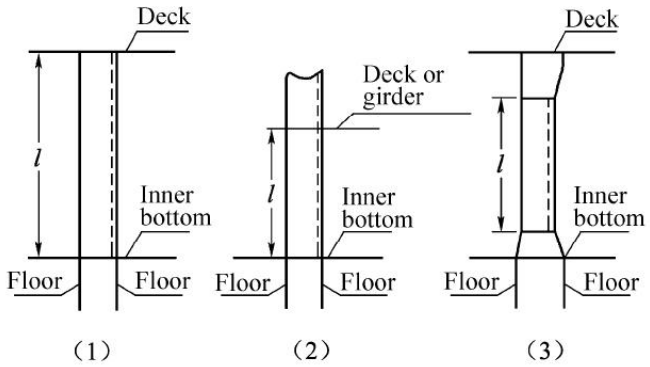

Figure 2.12.5.2

2.12.5.3 The plating thickness t of bulkheads with symmetrical corrugations is to comply with the requirements of 2.12.3.1 of this Section, and the following formula is to be complied with:

$$t \geq \frac{a}{85\sqrt{K}} \quad mm \qquad \text{at top}$$

$$t \geq \frac{a}{70\sqrt{K}} \quad mm \qquad \text{at bottom}$$

where: a — width of corrugation flange, in mm;

K — material factor. In the case of higher tensile steel where the material factor for a lower strength level can still satisfy the requirements for plate buckling check (see also 1.5.9, Chapter 1 of this PART) in direct calculation, the value of K for a lower strength level may be taken.

2.12.5.4 The plating thickness at the mid-span of corrugated bulkheads is to be kept up to not less than $0.2l$ above the mid-span.

2.12.6 Double plate bulkheads

2.12.6.1 The section modulus W of webs of double plate bulkheads is not to be less than that obtained from the following formula:

$$W = Cshl^2K \quad cm^3$$

where: s — spacing of webs, in m, see Figure 1.2.4.4 of Chapter 1 of this PART;

h — vertical distance, in m, measured from the mid-span to the bulkhead deck at side, but to be taken as not less than 2 m;

l — span of webs, in m;

C — coefficient, to be taken according to the end fixity as specified in Table 2.12.6.1;

K — material factor.

Value of coefficient *C* **Table 2.12.6.1**

Upper end / Lower end	Directly connected to deck	As shown in Figure 2.12.5.2(2) or (3)
As shown in Figure 2.12.5.2(1) or (2) or (3)	3.96	3.00

2.12.6.2 The scantlings of double plate bulkheads are to comply with the requirements of 2.12.3.1 and 2.12.6.1 of this Section and in addition, the following requirements:

(1) The plating thickness t_p of double plate bulkheads is to comply with the following requirements:

$$t_p \geq \frac{s}{75\sqrt{K}} \quad mm \quad \text{at top}$$

$$t_p \geq \frac{s}{65\sqrt{K}} \quad mm \quad \text{at bottom}$$

where: s — spacing of webs, in mm;

K — material factor. In the case of higher tensile steel where the material factor for a lower strength level can still satisfy the requirements for plate buckling check (see also 1.5.9, Chapter 1 of this PART) in direct calculation, the value of K for a lower strength level may be taken.

(2) The plating thickness t_w and the shear area A_w of the web of double plate bulkheads are to comply with the following requirements:

$$t_w \geq \frac{b}{85\sqrt{K}} \quad mm \quad \text{at top}$$

$$A_w \geq 0.12\frac{W}{l} \quad cm^2$$

$$t_w \geq \frac{b}{75\sqrt{K}} \quad mm \quad \text{at bottom}$$

$$A_w \geq 0.18\frac{W}{l} \quad cm^2$$

where: b — spacing of plates of double plate bulkheads, in mm;

W — section modulus required in 2.12.6.1 of this Section, in cm³;

l — span of webs, in m;

K — material factor. In the case of higher tensile steel where the material factor for a lower

strength level can still satisfy the requirements for plate buckling check (see also 1.5.9, Chapter 1 of this PART) in direct calculation, the value of K for a lower strength level may be taken.

2.12.6.3 The plating thickness at the mid-span of double plate bulkheads is to be kept up to not less than $0.2l$ above the mid-span. Manholes or similar openings are not to be cut in the webs of double plate bulkheads within one-third of their length from either end.

2.12.7 Girders

2.12.7.1 The section modulus W of girders is not to be less than that obtained from the following formula:

$$W = 6.6bhl^2K \quad \text{cm}^3$$

where: b— breadth of the area supported by the girder, in m;

h— vertical distance, in m, measured from the mid-span of girders to the bulkhead deck at side, but to be taken not less than 2 m;

l — span of girder, in m;

K— material factor.

2.12.7.2 The web depth of girders is not to be less than 2.5 times that of the supported bulkhead stiffeners, and the breadth of the face plate of girders is not to be more than the web depth or 35 times the thickness of the face plate.

2.12.7.3 The girder ends are to be connected by brackets. The brackets are to extend to the adjacent frames or bulkhead stiffeners. The scantlings of brackets are to comply with the relevant provisions in 1.2.7 of this PART.

2.12.8 Watertight bulkhead steps

2.12.8.1 The section modulus W of beams of decks or flats forming the steps in bulkheads is not to be less than that obtained from the following formula:

$$W = 4.2shl^2K \quad \text{cm}^3$$

where:

s — spacing of beams, in m;

h — vertical distance, in m, measured from the deck or flat forming bulkhead steps to the bulkhead deck at side, but to be taken not less than 2 m;

l — span of beams, in m, but to be taken not less than 2 m;

K — material factor.

2.12.8.2 The thickness of plating of the deck or flat forming the steps in bulkheads is to be 1 mm thicker than that required in 2.12.3.1 of this Section, and in this case s in the formula is to be taken as the spacing of beams.

2.12.8.3 The thickness of plating of the deck or flat forming the steps in bulkheads and the scantlings of beams are in no case to be less than those required, as appropriate, in Sections 4 and 8 of this Chapter for deck plating and beams.

Section 13 DEEP TANKS

2.13.1 General requirements

2.13.1.1 The deep tanks referred to in this Section are those loaded with liquids, such as water, oil fuel, vegetable oil, spoil, etc., which form a part of hull within tank or 'tween deck.

2.13.1.2 For ballast tanks with ballast water exchange by overflow method, the design pressure head h is, in addition to complying with the requirements of this Section, not to be less than the vertical distance from the calculation point to the overflow point.

2.13.2 Plane bulkheads

2.13.2.1 The thickness t of plane bulkhead plating is not to be less than that obtained from the following formula:

$$t = 3.95 s \sqrt{\rho h K} + 2.5 \quad \text{mm}$$

where: s — spacing of stiffeners, in m;

h — vertical distance, in m, measured from the lower edge of the plate in a strake to the top of the deep tank, or half the distance to the top of overflow, whichever is the greater;

ρ — density of liquid, in t/m^3, to be taken not less than 1.025;

K — material factor.

The thickness of bulkhead plating is not to be less than 8 mm for $L \geq 90$ m; not to be less than 7 mm for 60 m $\leq L <$ 90 m; and not to be less than 6 mm for $L <$ 60 m.

2.13.2.2 The thickness of bulkhead plating in way of bilges or bilge wells is to be increased by 2.5 mm.

2.13.2.3 The section modulus W of stiffeners of bulkheads is not to be less than that obtained from the following formula:

$$W = 8 s \rho h l^2 K \quad \text{cm}^3$$

where: s — spacing of stiffeners, in m;

l — span of stiffener, in m;

h — vertical distance, in m, measured from the mid-span of the stiffener to the top of the deep tank, or half the distance to the top of overflow, whichever is the greater. The ends of stiffeners are to be connected by brackets, and the scantlings of these brackets are to be in accordance with the relevant requirements in 1.2.6 of this PART. The ends of the stiffeners may also be connected directly to the deck plating or girders provided that the other side of the deck plating or girder is connected to an adjacent member having at least the same cross section as and in line with the said stiffener;

ρ — density of liquid, in t/m^3, to be taken not less than 1.025;

K — material factor.

The section moment of inertia I of stiffeners is not to be less than that obtained from the following formula:

$$I = 2.3 W l / K \quad \text{cm}^4$$

where: W, l — same as defined above.

2.13.3 Bulkheads with symmetrical corrugations

2.13.3.1 The scantlings of the bulkheads are to be in accordance with the following requirements:

(1) The section modulus W of a corrugation over a spacing is not to be less than that obtained from the following formula:

$$W = Cs\rho hl^2K \quad \text{cm}^3$$

where: l — span of stiffener, in m;

h — vertical distance, in m, measured from the mid-span of the corrugation to the top of the deep tank or half the distance to the top of overflow, whichever is the greater;

ρ — density of liquid, in t/m^3, to be taken not less than 1.025;

s — spacing of corrugation, in m;

C — coefficient, to be taken according to the end fixity as specified in Table 2.13.3.1;

K — material factor.

Value of coefficient *C* **Table 2.13.3.1**

Upper end / Lower end	Directly connected to deck	As shown in Figure 2.12.5.2(2) or (3) of this Chapter
As shown in Figure 2.12.5.2(1) or (2) or (3) of this Chapter	13.3	10.3

(2) The angle α between web and flange of corrugations is not to be less than 40°.

(3) Where the span of corrugations exceeds 15 m, a horizontal girder is to be arranged near the mid-span.

2.13.3.2 The plating thickness t of corrugated bulkheads is to comply with the requirements of 2.13.2.1 of this Section, and the following formula is to be complied with:

$$t \geq \frac{a}{70\sqrt{K}} \quad \text{mm}$$

where: a — width of corrugation flange, in mm;

K — material factor. In the case of higher tensile steel where the material factor for a lower strength level can still satisfy the requirements for plate buckling check (see also 1.5.9, Chapter 1 of this PART) in direct calculation, the value of K for a lower strength level may be taken.

2.13.3.3 The plating thickness at the mid-span of corrugated bulkheads is to be kept up to not less than 0.2l above the mid-span.

2.13.4 Double plate bulkheads

2.13.4.1 The section modulus W of webs and the spacing b of plates of double plate bulkheads are not to be less than those obtained from the following formulae:

$$W = Cs\rho hl^2K \quad \text{cm}^3$$

$$b = 40l \quad \text{mm}$$

where: s — spacing of webs, in m;

h — vertical distance, in m, measured from the mid-span to the top of the deep tank or half the distance to the top of overflow, whichever is the greater;

ρ — density of liquid, in t/m^3, to be taken not less than 1.025;

l — span of web, in m;

C — coefficient, to be taken according to the end fixity as specified in Table 2.13.4.1;

K — material factor.

Value of coefficient *C* **Table**

2.13.4.1

Upper end / Lower end	Directly connected to deck	As shown in Figure 2.12.5.2(2) or (3) of this Chapter
As shown in Figure 2.12.5.2(1) or (2) or (3) of this Chapter	10.2	8

2.13.4.2 The plating thickness t_p of double plate bulkheads is to comply with the requirements of 2.13.2.1 of this Section and in addition, the following formulae are to be complied with:

$$t_p \geq \frac{s}{75\sqrt{K}} \quad \text{mm} \quad \text{at top}$$

$$t_p \geq \frac{s}{65\sqrt{K}} \quad \text{mm} \quad \text{at bottom}$$

where: s — spacing of webs, in mm;

K— material factor. In the case of higher tensile steel where the material factor for a lower strength level can still satisfy the requirements for plate buckling check (see also 1.5.9, Chapter 1 of this PART) in direct calculation, the value of K for a lower strength level may be taken.

2.13.4.3 The plating thickness t_w and shear area A_w of webs of double plate bulkheads are to comply with the following requirements:

$$t_w \geq \frac{b}{85\sqrt{K}} \quad \text{mm} \quad \text{at top}$$

$$A_w \geq 0.07\frac{W}{l} \quad \text{cm}^2$$

$$t_w \geq \frac{b}{75\sqrt{K}} \quad \text{mm} \quad \text{at bottom}$$

$$A_w \geq 0.10\frac{W}{l} \quad \text{cm}^2$$

where: b — spacing of plates of double plate bulkheads, in mm;

W — section modulus required in 2.13.4.1 of this Section, in cm³;

l — span of webs, in m;

K — material factor. In the case of higher tensile steel where the material factor for a lower strength level can still satisfy the requirements for plate buckling check (see also 1.5.9, Chapter 1 of this PART) in direct calculation, the value of K for a lower strength level may be taken.

2.13.4.4 The plating thickness at the mid-span of double plate bulkheads is to be kept up to not less than $0.2l$ above the mid-span.

Manholes or similar openings are not to be cut in the webs of double plate bulkheads within one-third of their length from either end.

2.13.5 Girders

2.13.5.1 The section modulus W of girders is not to be less than that obtained from the following formula:

$$W = 11.7bph l^2 K \quad \text{cm}^3$$

where: b — breadth of the area supported by the girder, in m;

h — vertical distance, in m, measured from the mid-span of girder to the top of the deep tank, or half the distance to the top of overflow, whichever is the greater;

ρ — density of liquid, in t/m^3, to be taken not less than 1.025;

l — span of girder, in m;

K — material factor.

2.13.5.2 The section moment of inertia I of girders is not to be less than that obtained from the following formula:

$$I = 2.5Wl/K \quad \text{cm}^4$$

where: W, l, K — same as defined in 2.13.5.1 of this Section.

2.13.5.3 The web depth of girders is not to be less than 2.5 times that of the supported bulkhead stiffeners, and the breadth of the face plate of girders is not to be more than the web depth or 35 times the thickness of the face plate.

2.13.5.4 The girder ends are to be connected by brackets. The brackets are to extend to the adjacent frames or bulkhead stiffeners. The scantlings of the brackets are to comply with the relevant provisions in 1.2.7 of this PART.

2.13.6 Transverse side framing

2.13.6.1 Frames are to comply with the following requirements:

(1) The section modulus of frames other than those of forepeak and aft peak tanks is to be increased by 15% above that required in Section 7 of this Chapter.

(2) The section modulus W and section moment of inertia I of frames are to be not less than those obtained from the following formulae in addition to the requirement mentioned above:

$$W = 6.8s\rho hl^2K \quad \text{cm}^3$$

$$I = 3.5Wl/K \quad \text{cm}^4$$

where: s — spacing of frames, in m;

l — span of frame, in m, the vertical distance measured from the upper edge of floor or inner bottom to the side stringer, or between side stringers or from the side stringer to the 'tween deck;

h — vertical distance, in m, measured from the mid-span of frame to the top of the deep tank or half the distance to the top of overflow, whichever is the greater;

ρ — density of liquid, in t/m^3, to be taken not less than 1.025;

K — material factor.

(3) The arm length of end brackets of frames is to be increased by 20% above that required in 1.2.6 of this PART.

2.13.6.2 Side stringers supporting the frames are to comply with the requirements of 2.13.5.3 to 2.13.5.4 of this Section and in addition, to have a section modulus W and a moment of inertia I not less than those obtained from the following formulae:

$$W = 11.7b\rho hl^2K \quad \text{cm}^3$$

$$I = 2.5Wl/K \quad \text{cm}^4$$

where: b — breadth of the area supported by the stringer, in m;

h — vertical distance, in m, from the mid-span of stringer to the top of the deep tank, or half the distance to the top of overflow, whichever is the greater, but not less than the distance measured from the mid-span of stringer to the upper deck, or to a point

1.4d (d being the draught, in m) above the plate keel, whichever is the lesser;

ρ — density of liquid, in t/m^3, to be taken not less than 1.025;

l — span of stringer, in m;

K — material factor.

2.13.6.3 In deep tanks forward of 0.2L from F.P., side stringers are to be fitted and spaced not more than 5 m apart, or perforated flats having scantlings complying with the requirements of 2.15.1.11 of this Chapter are to be fitted. Where the length of the tank exceeds 14 m and perforated flats are fitted in lieu of the side stringers, web frames or transverse wash bulkheads are to be fitted.

2.13.6.4 The scantlings of web frames supporting the side stringers are to be calculated according to 2.7.4.1 of this Chapter. But the design head h is to be taken as the vertical distance measured from the side stringer to the top of the deep tank, or half the distance to the top of overflow, whichever is the greater, in m; but not to be less than the distance measured from stringers to the upper deck or to a point 1.4d (d being the draught, in m) above the plate keel, whichever is the lesser.

2.13.7 Longitudinal side framing

2.13.7.1 In addition to complying with the requirements of Section 7 of this Chapter, the section modulus W of side longitudinals is not to be less than that obtained from the following formula:

$$W=8.8s\rho hl^2K \quad \text{cm}^3$$

where: s — spacing of longitudinals, in m;

h — vertical distance, in m, measured from the longitudinal to the top of the deep tank or half the distance to the top of overflow, whichever is the greater;

ρ — density of liquid, in t/m^3, to be taken not less than 1.025;

l — span of longitudinal, in m;

K — material factor.

The end connections of side longitudinals are to comply with the relevant requirements of 2.7.5.7. The arm length of the end brackets is to be increased by 20% above that required in 1.2.6 of this PART.

2.13.7.2 The section modulus W of the web frames supporting the side longitudinals is not to be less than that obtained from the following formula:

$$W=11.7s\rho hl^2K \quad \text{cm}^3$$

where: s — spacing of web frames, in m;

h — vertical distance, in m, measured from the mid-span of web frame to the top of the deep tank, or half the distance to the top of overflow, whichever is the greater;

ρ — density of liquid, in t/m^3, to be taken not less than 1.025;

l — span of web frame, in m;

K — material factor.

2.13.7.3 The section moment of inertia I of web frames is not to be less than that obtained from the following formula:

$$I = 2.5Wl/K \quad \text{cm}^4$$

where: W, l, K — same as defined in 2.13.7.2 of this Section.

2.13.7.4 In deep tanks forward of 0.2L from F.P., the section modulus of web frames supporting the side longitudinals is to be increased by 20% above that obtained from 2.13.7.2 of this Section.

In general, the spacing of web frames is not to be greater than 3.0 m for ships of 100 m in length or less and not greater than 4.2 m for ships of 300 m or over in length, and the intermediate values are to be obtained by interpolation. Where the depth of the tank exceeds 16 m, perforated flats are to be fitted, and transverses are to be fitted in way of the web frames.

2.13.8 Deck plating and framing

2.13.8.1 In addition to complying with the requirements of Section 4 of this Chapter, the plating thickness t of the deck (or flat) of deep tanks is not to be less than that obtained from the following formula:

$$t = 3.95s\sqrt{\rho hK} + 3.5 \quad \text{mm}$$

where: s — spacing of frames, in m;

h — vertical distance, in m, measured from deck (or flat) to the top of the deep tank, or half the distance to the top of overflow, whichever is the greater;

ρ — density of liquid, in t/m^3, to be taken not less than 1.025;

K — material factor.

The plating thickness t of the deck (or flat) is not to be less than 8 mm for ship's length $L \geq 90$ m; 7 mm for 60 m $\leq L <$ 90 m; 6 mm for $L <$ 60 m.

2.13.8.2 In addition to complying with the requirements of Section 8 of this Chapter, the section modulus W of longitudinals or beams of the decks (or flats) in deep tanks is not to be less than that obtained from the following formula:

$$W = 8.8s\rho hl^2K \quad \text{cm}^3$$

where: s — spacing of longitudinals or beams, in m;

h — vertical distance, in m, measured from deck (or flat) to the top of the deep tank, or half the distance to the top of overflow, whichever is the greater;

ρ — density of liquid, in t/m^3, to be taken not less than 1.025;

l — span of longitudinal or beam, in m;

K — material factor.

The section moment of inertia I is not to be less than that obtained from the following formula:

$$I = 2.3Wl/K \quad \text{cm}^4$$

where: W, l, K — same as defined above.

2.13.8.3 In addition to complying with the requirements of Section 8 of this Chapter, the section modulus W of girders or transverses of decks (or flats) in deep tanks is not to be less than that obtained from the following formula:

$$W = 11.7S\rho hl^2K \quad \text{cm}^3$$

where: S — spacing of girders or transverses, in m;

h — vertical distance, in m, measured from deck (or flat) to the top of the deep tank, or half the distance to the top of the overflow, whichever is the greater;

ρ — density of liquid, in t/m^3, to be taken not less than 1.025;

l — span of girder or transverse, in m;

K — material factor.

The section moment of inertia I is not to be less than that obtained from the following formula:

$$I = 2.5Wl/K \quad \text{cm}^4$$

where: W, l, K — same as defined above.

2.13.8.4 The web depth of deck girders or transverses is to comply with the relevant requirements of Section 8 of this Chapter.

2.13.8.5 In deep tanks forward of 0.2L from F.P., the spacing of deck transverses supporting the deck longitudinals is to be the same as that of web frames as provided in 2.13.7.4 of this Section.

2.13.9 Bottom framing

2.13.9.1 The transversely framed single bottom in deep tanks forward of 0.2L from F.P. is to comply with the following requirements:

(1) Plate floors are to be fitted at every frame space, and the scantlings of floors are not to be less than those required in 2.15.1.1 of this Chapter. In way of web frames, the depth of floors and scantlings of face plates are not to be less than those of web frames.

(2) The section modulus W of the centerline girder is not to be less than the greater of those obtained from the following formulae:

$$W = 9sh_1l^2K \quad \text{cm}^3$$

$$W = 9.8\,s\,\rho h_2 l^2 K \quad \text{cm}^3$$

where: s — mean spacing supported by centerline girder, in m;

l — span of centerline girder, in m;

h_1 — vertical distance, in m, measured from the mid-span to upper deck at side; for the region forward of 0.15L from F.P., to 3 m above the deck for measuring minimum bow height (see Regulation 39 of the International Convention on Load Lines, 1966);

h_2 — vertical distance, in m, measured from the mid-span to the top of the deep tank, or half the vertical distance to the top of overflow, whichever is the greater;

ρ — density of liquid, in t/m^3, to be taken not less than 1.025;

K — material factor.

The section moment of inertia I is not to be less than that obtained by the following formula:

$$I = 2.5Wl/K \quad \text{cm}^4$$

where: W, l, K — same as defined above.

(3) Intercostal side girders are to be fitted and spaced not more than three frame spaces apart. The scantlings of intercostal side girders are to be the same as those of floors.

2.13.9.2 For longitudinally framed single bottom in deep tanks forward of 0.2L from F.P., the spacing of plate floors supporting longitudinals is to be the same as that of the web frames as provided in 2.13.7.4 of this Section. The plate floors are to be supported by a continuous centreline girder or a longitudinal bulkhead. The scantlings of plate floors and centreline girders are to comply with the relevant requirements of Section 3, Chapter 6 of this PART.

2.13.10 Wash bulkheads

2.13.10.1 Where a deep tank extends from side to side of the ship, a wash bulkhead is to be fitted on the centreline. Where the widest breadth of the tank exceeds 0.5B within the region forward of 0.3L from F.P., a wash bulkhead is to be fitted on the centreline of the tank. Where the widest breadth of the tank exceeds 0.7B, it is recommended that a longitudinal bulkhead be fitted on the centreline of the tank.

2.13.10.2 The thickness of the wash bulkhead is to be the same as that required for the bulkheads mentioned in this Section. The section modulus of the stiffeners of the wash bulkhead is to be equal to 50% of that of those bulkheads, but h is to be measured to the top of the deep tank. The stiffeners are to be connected by brackets at both ends. The area of perforations is not to be less than 5% nor more than 10% of the total area of the bulkhead.

Section 14 STEMS, STERN FRAMES, BULBOUS BOWS AND PROPELLER SHAFT BRACKETS

2.14.1 Stems

2.14.1.1 The cross-sectional area A of bar stems up to 0.5 m above the summer load waterline is not to be less than the following:

$$A = 1.2L \quad \text{cm}^2 \text{ for } L < 90 \text{ m}$$
$$A = 1.63L - 38 \quad \text{cm}^2 \text{ for } L \geq 90 \text{ m}$$

where: L — length of ship, in m.

From a position above 0.5 m from the summer load waterline, the cross-sectional area may be gradually tapered to the stem head where the area may be reduced by 25%.

2.14.1.2 The thickness t of plate stems up to 0.5 m above the summer load waterline is not to be less than that obtained from the following formula:

$$t = (0.08L + 5.5)\sqrt{K} \quad \text{mm}$$

where: L — length of ship, in m, but not to be taken greater than 230 m;

K — material factor.

From a position above 0.5 m from the summer load waterline, the plate thickness may be gradually tapered to the stem head where the thickness may be the same as that of the shell at ends.

Plate stems are to be supported by horizontal webs spaced not more than 1 m apart, and the web thickness is not to be less than the thickness of the adjacent shell plating. The webs are to be extended aft to be connected to frames or side stringers, but at least beyond the butts of stem plates and shell plating.

Where the radius of curvature of the stem is large, a centreline vertical web is to be fitted, having the same thickness as the horizontal webs.

2.14.1.3 Cast steel stems are to be easy for manufacture, and all fillets are to have adequate radii. The sectional area of cast steel stems is not to be less than that of bar stems required in 2.14.1.1 of this Section. Cast steel stems are to be provided with rib reinforcement.

2.14.2 Stern frames without rudder post

2.14.2.1 The stern frame without rudder post is composed of sole piece, propeller post and propeller boss.

2.14.2.2 The scantlings of fabricated propeller posts (as shown in Figure 2.14.2.2) are not to be less than those obtained from the following formulae:

Length of stern frame: $a = 46\sqrt{L}$ mm

Thickness of stern frame: $t = 2.3\sqrt{L} + 3$ mm

where: L — length of ship, in m.

2.14.2.3 The scantlings of cast propeller posts (as shown in Figure 2.14.2.3) are not to be less than those obtained from the following formulae:

Length of stern frame: $a = 41\sqrt{L}$ mm

Thickness of stern frame: $t_1 = 3\sqrt{L}$ mm

$t_2 = 4\sqrt{L}$ mm

Radius of fillet: $R = 4.9\sqrt{L}$ mm

where: L — length of ship, in m.

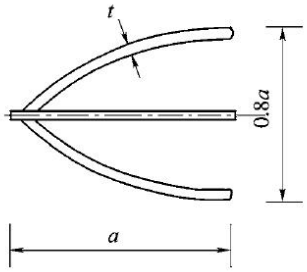

Figure 2.14.2.2(1)

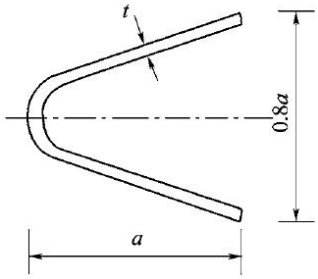

Figure 2.14.2.2(2)

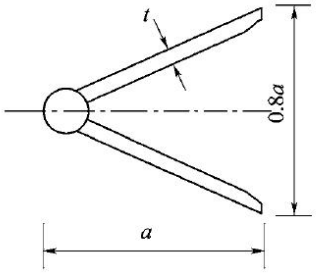

Figure 2.14.2.2(3)

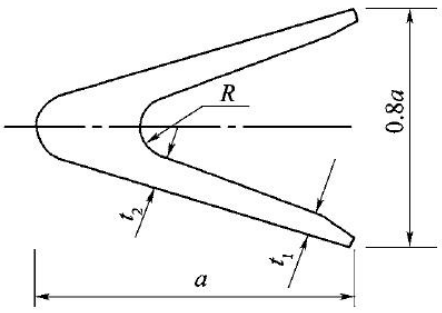

Figure 2.14.2.3

2.14.2.4 Fabricated or cast propeller posts are to be strengthened by horizontal brackets at positions depending upon the hull framing and the structural arrangements of propeller posts, but the spacing of the webs is not to exceed 650 mm. Cast steel stern frames are to be easy for manufacture, and all fillets are to have adequate radius; where the radius of curvature is large, a vertical web is to be fitted.

2.14.2.5 The section modulus W_z of sole pieces (see Figure 2.14.2.5) about the vertical neutral axis (z-axis) at any considered section, is not to be less than that obtained from the following formula:

$$W_z = \frac{K}{80} Px \quad \text{cm}^3$$

where: P — supporting force exerting by the sole piece on rudder blade, in N, to be calculated according to the relevant provisions of Section 1, Chapter 3 of this PART;

K — material factor according to 1.3.1.7 of this PART for fabricated sole pieces; material factor according to 3.1.1.3 of this PART for cast sole pieces;

x — distance between the axis of rudder stock and the section under consideration, in m, to be taken not less than $0.5l_s$, l_s being the maximum distance, in m, (see Figure 2.14.2.5).

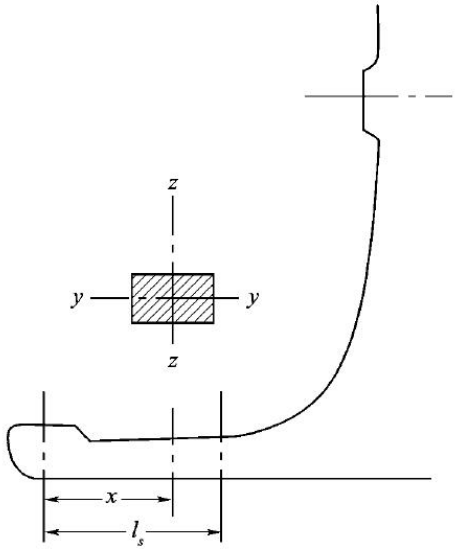

Figure 2.14.2.5

2.14.2.6 The section modulus W_y of sole pieces about the horizontal neutral axis (y-axis) at any considered section is not to be less than that obtained from the following formula:

$$W_y = 0.5W_z \quad \text{cm}^3$$

where: W_z — section modulus, in cm³, to be calculated according to 2.14.2.5 of this Section.

2.14.2.7 The sectional area A_s at any section of the sole piece is not to be less than that obtained from the following formula:

$$A_s = \frac{K}{48}P \quad \text{mm}^2$$

where: P, K — see 2.14.2.5 of this Section.

2.14.2.8 Within the length l_s, the equivalent stress σ_e of any section of sole pieces is to be determined from following formula:

$$\sigma_e = \sqrt{\sigma^2 + 3\tau^2} \le 115/K \quad \text{N/mm}^2$$

where: $\sigma = \frac{Px}{W_z}$, in N/mm², where: P, x — see 2.14.2.5 of this Section, W_z being the section modulus of the considered section about z-axis, in cm³;

$\tau = \frac{P}{A_s}$, in N/mm², where: P — see 2.14.2.5 of this Section, A_s being the sectional area of the section under consideration, in mm²;

K — see 2.14.2.5 of this Section.

2.14.2.9 In fabricated sole pieces, transverse webs are to be fitted and spaced not more than 760 mm apart. Where the breadth of the fabricated sole pieces exceeds 900 mm, a centreline vertical web is to be fitted.

2.14.2.10 The sole piece is to extend forward from the fore end of the propeller boss for at least 3 frame spaces and to be efficiently connected to the plate keel. The sectional area of the extended portion may be reduced gradually to the area required for effective connection with the plate keel.

2.14.2.11 The stern tube shaft is to be efficiently connected to the floor or bulkhead, and the thickness of the floor is to be increased by 3 mm.

2.14.2.12 The finished thickness t of the propeller boss in way of the passage of the stern tube shaft or propeller shaft is not to be less than that obtained from the following formula:

$$t = 0.1d_s + 60 \quad \text{mm, but not greater than } 0.3d_s$$

where: d_s — diameter of stern tube shaft or propeller shaft, in mm.

2.14.3 Propeller posts of twin screw ships

2.14.3.1 The dimensions of propeller posts which are built integral with the hull of twin screw ships (see Figures 2.14.3.1(1), (2)) are not to be less than as given below:

Breadth of section:	$b = 33\sqrt{L}$	mm
Thickness of section:	$t_1 = 3.3\sqrt{L}$	mm
	$t_2 = 3.7\sqrt{L}$	mm
	$t_3 = 4.5\sqrt{L}$	mm
Radius of fillet:	$R = 4.4\sqrt{L}$	mm

where: L — length of ship, in m.

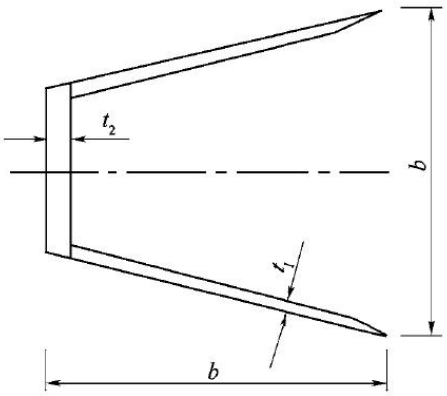

Figure 2.14.3.1(1)

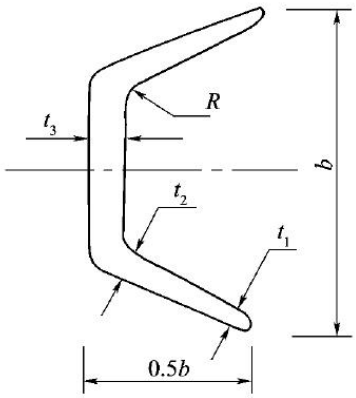

Figure 2.14.3.1(2)

2.14.4 Propeller clearances

2.14.4.1 It is recommended that the minimum clearances (see Figure 2.14.4.1) between the propeller and the stern frame or between the propeller and the rudder be not less than the following:

$$a = 0.12D \quad \text{m}$$
$$b = 0.20D \quad \text{m}$$
$$c = 0.14D \quad \text{m}$$
$$d = 0.04D \quad \text{m}$$

where: D — diameter of propeller, in m.

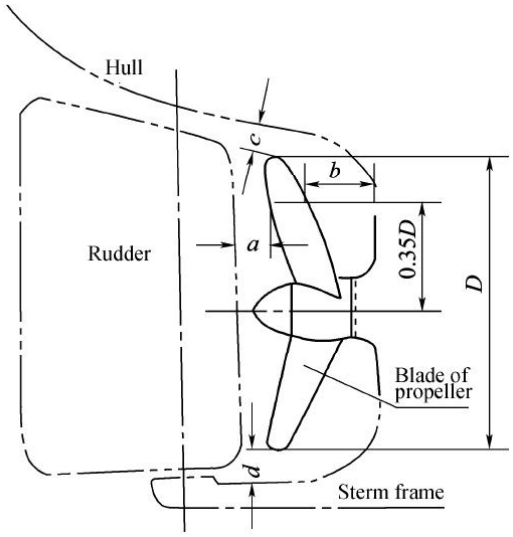

Figure 2.14.4.1

2.14.5 Bulbous bows

2.14.5.1 Where a bulbous bow is fitted, the structural arrangements are to be such that the bulb is adequately supported and integrated into the fore peak structure. The bulb is in general to be strengthened as follows:

(1) At the fore end of the bulb, the structure is to be supported by horizontal diaphragm plates spaced about 1 m apart in conjunction with the center girder;

(2) Vertical transverse diaphragm plates are to be arranged in way of the transition from the peak framing to the bulb framing;

(3) In way of a long bulb, additional strengthening in the form of transverse wash bulkheads or web frames spaced about 5 frame spaces apart are generally to be fitted;

(4) In way of a wide bulb, additional strengthening in the form of a centreline wash bulkhead is generally to be fitted;

(5) The shell plating is to be increased in thickness at the fore end of the bulb and in other areas likely to be damaged by the anchors and chain cables. The increased plate thickness may be the same as that required for plate stems.

2.14.6 Propeller shaft brackets

2.14.6.1 Propeller shaft brackets may be made of steel castings or fabricated from plates, or made of cast or forged pieces connected by welding. The connection of the arms to the bearing boss is to be made by full penetration welding.

2.14.6.2 The scantlings of each arm and shaft bossing of herringbone propeller shaft bracket are not to be less than as given below:

Thickness of arm:	$t = 0.45d_s$	mm
Cross sectional area of arm:	$A = 0.45\,d_s^2$	mm²
Thickness of shaft bossing:	$t = 0.33d_s$	mm
Length of shaft bossing:	$l = 3d_s$	mm

where: d_s — diameter of stern tube shaft or propeller shaft at the location of shaft bracket, in mm.

2.14.6.3 The hull framing in way of the bracket palm is to be strengthened and the shell plating in way is to be increased in thickness as required in 2.3.6.1 of this Chapter. Bracket arms are to be carried through the shell plating and efficiently attached to floors, girders and shell plating.

Section 15 STRENGTHENING AT ENDS OF SHIP

2.15.1 Fore peak strengthening

2.15.1.1 Solid floors are to be fitted at every frame. The web depth h and thickness t and the face plate sectional area A of the floors are not to be less than those obtained from the following formulae:

$$h = 85D + 140 \quad \text{mm, but need not be greater than 1500 mm}$$

$$t = (0.03L+6)\sqrt{K} \quad \text{mm}$$

$$A = 0.85BK \quad \text{cm}^2$$

where: B — breadth of ship, in m;

D — moulded depth of ship, in m;

L — length of ship, in m, to be taken as not greater than 200 m;

K — material factor.

2.15.1.2 Centreline keelson is to be fitted at the longitudinal centreline section. The web depth and thickness and the face plate sectional area are to be as those required in 2.15.1.1 of this Section for solid floors.

2.15.1.3 For the extremely narrow bottom, the centreline keelson not extended to the bottom may be accepted, but the depth of the keelson is to be approximately equal to 1/3 of the floor depth. Or alternatively, the centreline keelson may be entirely omitted provided that the web of floors is fitted with horizontal stiffeners and that a perforated flat, instead of a face plate, is fitted at the top edge of the web.

2.15.1.4 In the case as mentioned in 2.15.1.3 of this Section, a centreline keelson gradually tapered off over several frame spaces is to be fitted forward of the collision bulkhead as the continuation of the centreline girder or centreline keelson abaft the collision bulkhead.

2.15.1.5 Where the side shell is framed transversely, panting beams spaced not more than 2 m apart vertically are to be fitted at alternate frames, from the top of floors up to the lowest deck, and at least to 1 m above the full-load waterline. The cross-sectional area A and minimum section moment of inertia I of the panting beams are not to be less than:

$$A = (0.27L + 8)K \quad \text{cm}^2$$

$$I = ceh_i l^2 \quad \text{cm}^4$$

where: L — length of ship, in m, to be taken as not greater than 250 m;

c — horizontal spacing of panting beams, in m;

e — vertical spacing of panting beams, in m;

h_i — vertical distance, in m, measured from the beam to 3 m above the minimum bow height required by load line, and not to be less than that to upper deck;

l — span of panting beam, in m;

K — material factor.

2.15.1.6 Where a fore peak space is used as a tank and the breadth of the tank at its widest point exceeds 0.5B (B being the breadth of ship), efficient supporting members or wash bulkheads are to be fitted to support the panting beams. The wash bulkheads are to comply with the requirements of 2.13.10.2 of this Chapter.

2.15.1.7 Where the length of the fore peak space exceeds 10 m, additional transverse strengthening in the form of transverse wash bulkheads or web frames is to be provided. Transverse wash bulkheads are to comply with the provisions in 2.13.10.2 of this Chapter while web frames are to comply with the provisions in 2.7.2.8 of this Chapter.

2.15.1.8 Where the side shell is framed transversely, side stringers with flange or face plate are to be fitted at each panting beam, and are to have a web depth h and thickness t not less than:

$$h = 5.6L + 166 \quad \text{mm} \quad \text{for } L < 90\text{m}$$
$$h = 3.0L + 400 \quad \text{mm} \quad \text{for } L \geq 90\text{m}$$
$$t = 0.023L + 6 \quad \text{mm}$$

where: L — length of ship, in m, to be taken as not greater than 250 m.

2.15.1.9 Brackets are to be fitted at the lower edge of connections between side stringers and frames, the thickness of brackets is not to be less than that of the side stringer web and the brackets are to be extended to the flange or face plate of side stringers. Where panting beams are fitted, the arm length of brackets along the frames is not to be less than 75% the web depth of side stringers, and where no panting beams are fitted, the arm length is not to be less than 50% the web depth of side stringers. The webs of side stringers are to be welded to the frames.

2.15.1.10 Where the side shell is framed transversely and if perforated flats are fitted in lieu of the panting beams in association with stringers, the flats are to be spaced not more than 2.5 m apart and are to be fitted vertically from the top of floors to the lowest deck above the full-load waterline, but not below 1.0 m above the full-load waterline.

2.15.1.11 Where the side shell is framed transversely, the perforated flats are to comply with the following requirements:

(1) The area of perforations in each flat is not to be less than 10% of the total area of the flat.

(2) The plate thickness t of the perforated flat is not to be less than that obtained from the following formula:

$$t = 0.023L + 5 \quad \text{mm}$$

where: L — length of ship, in m.

(3) Where the perforated flat is framed transversely, one beam is at least to be fitted at alternate frames below the perforated flat, and their sectional area A without attached plating is not to be less than that obtained from the following formula:

$$A = (0.13L + 4)CK \quad \text{cm}^2$$

where: L — length of ship, in m.

C — coefficient, C =1 when beams are fitted at alternate frames; C =0.5 when beams are fitted at every frame;

K — material factor.

Where the perforated flat is framed longitudinally, an appropriate number of transverses are to be fitted below the perforated flat, and the size of transverses and longitudinals is to be specially considered.

(4) Scantlings of the brackets connecting the beams of the perforated flat to the frames are to comply with the requirements in 1.2.6 of this PART.

2.15.1.12 Where the side shell is framed longitudinally and the depth of the forepeak exceeds 10 m, one or more perforated flats are to be provided at suitable positions, or one or more panting beams as required in 2.15.1.5 of this Section are to be provided in way of each web frame.

2.15.1.13 Where the side shell is framed longitudinally, an adequate number of transverses are to be arranged at the top of the forepeak and at perforated flats (if fitted). The brackets connecting transverses to web frames are to be in accordance with the requirements of 1.2.7 of this PART.

2.15.1.14 Where the side shell is framed longitudinally, the perforated flats are to comply with the requirements of 2.15.1.11(1) to (3) and brackets are to be fitted at the connection between the beams of perforated flats and the side plating and extended to the adjacent side longitudinals.

2.15.1.15 Brackets are to be fitted in way of fore edge of the connection between web frames and side longitudinals. The thickness of brackets is not to be less than the web thickness of web frames and the brackets are to be extended to the face plate of web frames. Where panting beams are fitted, the arm length of brackets along the side longitudinals is not to be less than 75% of the web depth of web frames and where no panting beams are fitted, the arm length of brackets along the side longitudinals is not to be less than 50% of the web depth of web frames.

2.15.1.16 Longitudinally framed bottom structure is to be specially considered.

2.15.2 Strengthening at sides abaft the fore peak tank

2.15.2.1 Where the side shell is framed transversely, side framing within the region from 0.15L from F.P. to the collision bulkhead is to be strengthened as follows:

(1) Where the span of main frames does not exceed 9 m, intercostal side stringers are to be fitted in line with the side stringers or perforated flats in the fore peak tank.

(2) Where the span of main frames does not exceed 9 m and if intercostal side stringers are omitted, the side shell plating in the region concerned is to be increased in thickness by the percentages given below:

where $L \leq 150$ m, by 15% of the thickness as required in this Chapter;

where $L \geq 200$ m, by 5% of the thickness as required in this Chapter.

For intermediate values of L, the percentage increase is to be obtained by interpolation.

(3) Where the span of main frames exceeds 9 m, intercostal side stringers are to be fitted and to extend abaft to 0.2L from the F.P. in line with the side stringers or perforated flats in the fore peak tank.

(4) Where the span of frames exceeds 2.6 m in the lower 'tween deck or 3 m in the upper 'tween deck, intercostal side stringers are to be fitted. Where the shell plating is increased according to the requirements in (2) above, the side stringers may be omitted.

2.15.2.2 The web depth of intercostal side stringers as required in 2.15.2.1 of this Section may be the same as that of frames. However, the web plate of such stringers is to be gradually increased in depth for at least two frame spaces to the collision bulkhead so that the depth at the bulkhead is the same as that of the side stringers in the fore peak tank. Where perforated flats are fitted in the fore peak tank, the depth of the web of side stringers is to be calculated according to 2.15.1.8 of this Section. The web thickness t and the face plate sectional area A of the intercostal side stringers are not to be less than those obtained from the following formulae:

$$t = 0.023L + 6 \quad \text{mm, but need not be greater than 12 mm}$$

$$A = 0.14L + 1 \quad \text{cm}^2\text{, but not to be less than 7 cm}^2$$

where: L — length of ship, in m.

2.15.3 Strengthening of bottom forward

2.15.3.1 Where the length L of the ship is equal to 65 m or over and the draught forward in navigation is less than $0.04L$, the flat portion of bottom from F.P. is to be strengthened. The transverse extent of strengthening is not to be less than $0.014B$ (B being the breadth of the ship) above the base line, but need not be greater than 0.28 m, and the length X from the end line of the longitudinal extent of strengthening to F.P. is not to be less than that obtained from the following formula:

$$X = \left(0.65 - \frac{C_b}{2}\right)L \quad \text{m}$$

where: L — length of ship, in m;

C_b — block coefficient, to be taken as 0.7 for $C_b < 0.7$, and 0.8 for $C_b > 0.8$.

For every oil tanker subject to Regulation 18 of MARPOL Annex I, the minimum forward draught is to be determined according to the conditions in which only segregated ballast tanks are used.

2.15.3.2 Where strengthening is required, double bottom framed transversely is to be strengthened as follows:

(1) Plate floors are to be fitted at every frame space.

(2) Side girders are in general to be fitted not more than three frame spaces apart, and half-depth flanged side girders are to be fitted midway between the side girders. The side girders and half-depth side girders are to be extended as far forward as practicable.

2.15.3.3 Where strengthening is required, double bottom framed longitudinally is to be strengthened as follows:

(1) Plate floors are to be fitted at alternate frames, and spaced not more than 2.5 m apart.

(2) The section modulus of bottom longitudinals is to be increased by 10% above that obtained from the formula in 2.6.12.2 of this Chapter, and in this case, l in the formula is not to be less than 1.85 m.

(3) Side girders are in general to be fitted not more than three times the spacing of longitudinals apart and are to be extended as far forward as practicable.

2.15.3.4 Where strengthening is required, single bottom framed transversely is to be strengthened as follows:

(1) In addition to complying with the requirements of 2.15.1.1 of this Section, floors are to be increased gradually in depth towards the fore end as far as practicable, and the floor web is to be adequately increased in thickness so as to ensure its stability. The sectional area of the face plate of floors is to be increased by 50% over the value required in 2.15.1.1 of this Section and flanges are not to be substituted for face plates of floors.

(2) Side keelsons are to be fitted not more than three frame spaces apart, and half-depth side keelsons or other equivalent bottom longitudinal stiffening members are to be fitted midway between the side keelsons and extended as far forward as practicable.

2.15.3.5 In the Where strengthening is required, the forward bottom plating is to be strengthened as follows:

(1) The thickness t of the forward bottom plating is not to be less than that obtained from the following formula:

$$t = CC_1\left(1.8 - 26\frac{d_1}{L}\right)\sqrt{\frac{seK}{s_b}} \quad \text{mm}$$

where: L — length of ship, in m;

d_1 — minimum draught forward in navigation, in m;

s — spacing of frames, in m;

s_b — standard spacing of frames, in m;

e — correction coefficient of longitudinal position, see Table 2.15.3.5;

C — coefficient: $C = 7.3 + 0.081L$ for $65 \text{ m} \le L \le 145$ m;

$C = 19.0$ for $145 < L \le 200$ m;

$C = 23.6 - 0.023L$ for $200 < L \le 300$ m;

$C = 16.7$ for $L > 300$ m;

$C_1 = 1.2 - \frac{s}{2l}$, where l is the spacing of primary members, C_1 is to be taken as 1 for $C_1 > 1$;

K — material factor.

Correction Coefficient *e* **Table 2.15.3.5**

Position	e
Between $X - 0.125L$ to X from F.P.	$\frac{2f-1}{0.05 - C_b}$
Between F.P. and $X - 0.2L$ from F.P.	$0.5 + \frac{f}{0.9 - C_b}$
Others	1

where: C_b — see 2.15.3.1 of this Section;

f — the ratio of the distance of x, in m, from F.P. and length of ship L, in m, i.e. $f = X/L$;

X — see 2.15.3.1 of this Section.

(2) The strengthened forward bottom plating is to be gradually tapered to adjacent shell plating.

2.15.3.6 The forward bottom strengthening is to be verified by direct calculation assessment as specified in Appendix 4 of this Chapter if any of the following conditions applies:

(1) where the minimum forward draught of a ship is less than $0.01L$;

(2) where the arrangements of primary members do not comply with the relevant requirements of 2.15.3 of this Section.

2.15.3.7 In the strengthening region for single bottom framed longitudinally:

(1) Plate floors complying with the provisions of 2.15.3.4 (1) are to be fitted at alternate frames.

(2) The section modulus of bottom longitudinals is to be increased by 10% above that obtained from the formula in 2.6.12.2 of this Chapter, and in this case, l in the formula is not to be less than 1.85 m; side keelsons are to be fitted not more than three times the spacing of longitudinals apart and extended as far forward as practicable.

2.15.4 Aft peak strengthening

2.15.4.1 Plate floors are to be fitted at every frame space, the thickness of which is to be 1.5 mm thicker than that in the fore peak as required in this Section. In single screw ships, floors are to be carried well above the stern tube. In way of propeller posts, propeller shaft brackets and rudder

horns, the floors are generally to be carried to the top of the space and are to be increased in thickness.

2.15.4.2 Where the side shell is framed transversely, panting beams and side stringers spaced vertically not more than 2.5 m apart are to be fitted above the floors, or alternatively, perforated flats complying with the requirements of 2.15.1.11 of this Section are to be provided. The panting beams and side stringers as well as the connection of these members to frames are to comply with the requirements for the fore peak.

2.15.4.3 Where the side shell is framed longitudinally, suitable transverses are to be arranged at the top of the tank and the brackets connecting the transverses to web frames are to comply with the requirements of 1.2.7 of this PART.

2.15.4.4 A centreline wash bulkhead is in general to be arranged in tanks, the upper part of the after peak space and counter or cruiser stern. Where the overhang is very large, additional longitudinal wash bulkheads may be required port and starboard. The wash bulkheads are to comply with the requirements of 2.13.10.2 of this Chapter, and stiffeners are to be fitted at every frame space.

2.15.5 Side strengthening above the aft peak

2.15.5.1 Where the side shell of 'tween deck spaces above the after peak tank is transversely framed and the height of such spaces is more than 3 m, intercostal panting stringers are to be provided, of which the web depth is to be the same as that of frames. The web thickness and the sectional area of face plates of these intercostal stringers are to comply with the requirements of 2.15.2.2 of this Section. Where no intercostal side stringer is fitted, the thickness of shell plating within the region is to be increased in accordance with the requirements of 2.15.2.1(2) of this Section.

2.15.5.2 Where the side shell of 'tween deck spaces above the after peak tank is transversely framed, web frames are to be fitted not more than 4 frame spaces apart. The section modulus W of web frames is not to be less than that obtained from the following formula:

$$W = 3.5Sdh\sqrt{D}\,K \quad \text{cm}^3$$

where: S — spacing of web frames, in m;

d — draught of ship, in m;

h — height of 'tween deck spaces, in m;

D — moulded depth, in m;

K — material factor.

2.15.5.3 Where the side shell of 'tween deck spaces above the after peak tank is framed longitudinally, web frames supporting longitudinals are to be fitted. The spacing of web frames is not to be greater than 2.5 m for ships of 100 m in length or less; and not greater than 3.5 m for ships of 300 m or over in length; the intermediate values are to be obtained by interpolation. The section modulus W of the frames is not to be less than that obtained from the following formula:

$$W = 4.4Sdh\sqrt{D}\,K \quad \text{cm}^3$$

where: S, d, h, D and K — the same as those in 2.15.5.2 of this section.

2.15.6 Structural strengthening for bow flare

2.15.6.1 For container ships, ro-ro ships, passenger ships, car carriers and the ships with the similar bow flare, the side structural strengthening at bow is to meet the requirements of Section 8, Chapter 7 of this PART.

Section 16 ENGINE SEATINGS AND SHAFT TUNNELS

2.16.1 Main engine seatings

2.16.1.1 The main engine seating is to be of ample strength and rigidity. It is generally to consist of two longitudinal girders with transverse diaphragms and transverse brackets fitted at every frame space. Transverse diaphragms are to be fitted between longitudinal girders and are to extend to the face plate of girders as far as practicable. Transverse brackets, the width of which is generally not to be less than their depth, are to be fitted at the outside of the longitudinal girders and welded to the face plate of the girders.

2.16.1.2 The longitudinal girders of the seating are to be in line with the bottom side girders. If it is impracticable to do so, partial girders of the same thickness as the bottom side girders are to be fitted under the longitudinal girders.

In particular cases, the partial girder may be in the form of a half-depth girder welded to the inner bottom plating and floors only.

2.16.1.3 Scantlings of structural members of main engine seatings

(1) For large low-speed diesel engines having a power of more than 1,470 kW, the horizontal face plate thickness t and the web thickness t_1 of longitudinal girders, and the thickness t_2 of transverse diaphragms and transverse brackets are not to be less than the values given below:

$$t = 1.44\sqrt[3]{p} + 10s \quad \text{mm}$$

$$t_1 = 0.65t\left(1+\frac{h-1}{10}\right) \quad \text{mm for } L \geq 90 \text{ m}$$

$$t_1 = 0.70t \quad \text{mm for } L < 90 \text{ m}$$

$$t_2 = 0.77t_1 \quad \text{mm for } L \geq 90 \text{ m}$$

$$t_2 = 0.80\ t_1 \quad \text{mm for } L < 90 \text{ m}$$

where: P — main engine power, in kW;

s — spacing of frames, in m;

h — web depth of longitudinal girders, in m.

(2) For main engines having a power of 1,470 kW or less, the web thickness of longitudinal girders is to be increased by 60% above that of the bottom side girders (for double bottom) or side keelsons (for single bottom) in way of the engine room in the case of diesel engines, and by 30% in the case of turbines or propulsion motors. In both cases, the longitudinal girders are to be provided with a continuous horizontal face plate having a thickness 40% greater than their web thickness. The longitudinal girders are to be gradually tapered off at their ends.

The thickness of the transverse diaphragms and transverse brackets is to be increased by 40% above that of the floors in the case of diesel engines, and by 30% in the case of turbines or propulsion motors. The transverse diaphragms and transverse brackets are to be provided with a face plate or flange.

(3) The scantlings of main engine seatings may be suitably reduced in the case of high-powered turbines, propulsion motors or medium/high speed diesel engines.

2.16.1.4 The horizontal face plates of longitudinal girders are to be stiffened in way of holding-down bolts by a suitable number of vertical brackets, and the depth of the brackets is to be twice their breadth.

2.16.1.5 Where the main engine seating or the thrust seating is directly bolted to the inner bottom, the thickness t_3 of the inner bottom plating in way is not to be less than that required as follows:

(1) for large low-speed diesel engines having a power of more than 1,470 kW, $t_3 = t$, t as defined in 2.16.1.3(1) of this Section;

(2) for main engines having a power of 1,470 kW or less, t_3 is to be equal to twice the thickness of the inner bottom plating in the region, but is not to be less than 20 mm;

(3) for high-powered turbines, t_3 will be specially considered.

The double bottom tanks within the above regions are not to be used for carrying oil fuel or water. Partial or half-depth girders are to be fitted close to holding-down bolts. The longitudinal division bulkheads and side girders in the adjacent oil or water tanks may be regarded as the partial girders at holding-down bolts.

2.16.2 Shaft tunnels

2.16.2.1 Shaft tunnels are to be of watertight construction.

2.16.2.2 The thickness of tunnel plating is to comply with the requirements of 2.12.3.1 of this Chapter for watertight bulkheads. If the top plating is curved, the thickness may be reduced by 10% in dry cargo holds. If the top plating is flat, it is not to be less than 1.1 times the thickness required for the watertight bulkheads.

The thickness of top plating of the tunnel under hatchways is to be increased by at least 2 mm, unless covered with wood ceiling as required in 3.3.1.5 of this PART.

2.16.2.3 Stiffeners of shaft tunnels are to be in line with the frames wherever possible, and their section modulus W is not to be less than that obtained from the following formula:

$$W = 6shl^2K \quad \text{cm}^3$$

where: s — spacing of stiffeners, in m;

h — the vertical distance, in m, measured from the mid-point of the vertical part of the stiffener to bulkhead deck;

l — the length of the vertical part of the stiffener, in m;

K — material factor.

Where the tunnel top is flat, the scantlings of the top beams are not to be less than those required for the beams in way of the steps in watertight bulkheads (see 2.12.8 of this Chapter).

The lower end of the vertical part of stiffeners is to be welded to the inner bottom.

2.16.2.4 Where shaft tunnels pass through or are adjacent to deep tanks, the adjacent bulkheads and their stiffeners are to comply with the requirements of Section 13 of this Chapter for deep tanks.

2.16.2.5 The structure of the thrust and tunnel recesses is to comply with the requirements for the steps in watertight bulkheads. Where these recesses are enclosed by deep tanks, the requirements for bulkheads and stiffeners of deep tanks are to be complied with.

2.16.2.6 The shaft tunnel is to be provided with an emergency exit leading to the weather deck, and the construction of the trunk of the exit is to comply with the requirements for watertight bulkheads. The closing appliance for the exit is to be capable of being operated from both sides.

Section 17 SUPERSTRUCTURES AND DECKHOUSES

2.17.1 General requirements

2.17.1.1 All ships are to be provided with forecastles or increased sheer to such a minimum bow height as to meet the requirements of their respective flag Administrations. The forecastles of bulk carriers, ore carriers and combination carriers are to be also in compliance with Section 13, Chapter 8 of this PART.

2.17.1.2 Where superstructures and deckhouses are subject to loading in excess of that as specified in this Section, the scantlings of their structural members are to be appropriately increased in addition to complying with the requirements of this Section.

2.17.1.3 Where long superstructures are provided within 0.5L midships, the deck structure of the 1st tier is to comply with the requirements for strength decks and side shell is to comply with the requirements for shell plating.

2.17.1.4 Where long deckhouses are provided within 0.5L midships, the thickness of plating and the size of framing of the 1st tier is to be increased according to the contribution of these deckhouses to the longitudinal bending of hull girders.

2.17.1.5 The deckhouses on forecastle deck of offshore supply ships are to comply with the requirements of Section 5, Chapter 11 of this PART.

2.17.1.6 Definitions of tiers of superstructures/deckhouses: The lowest, or first tier, is normally that tier which is directly situated on the uppermost continuous deck to which the Rule moulded depth D is to be measured. The second tier is the next tier above the lowest tier and so on.

2.17.1.7 The deck plating of No.N tier of superstructure/deckhouse is the top plating of this tier of superstructure/deckhouse.

2.17.1.8 Where a freeboard corresponding to or exceeding the uncorrected tabular values of the International Convention on Load Lines, 1966 can be obtained for a ship with excessive freeboard, i.e. by considering the ship to have a virtual moulded depth D' at least one standard superstructure height less than the Rule moulded depth D (see Figure 2.17.1.8), the 1st tier erection may be treated as the 2nd tier, and the 2nd tier as the 3rd tier when applying the requirements of this Section. The standard superstructure height h_s is to be obtained as follows:

$$h_s = 1.05 + 0.01L_L \quad \text{m, and } 1.8 \leq h_s \leq 2.3$$

where: L_L — load line length of ship, in m.

However, this does not apply to type ‘B’ ships with reduced freeboard.

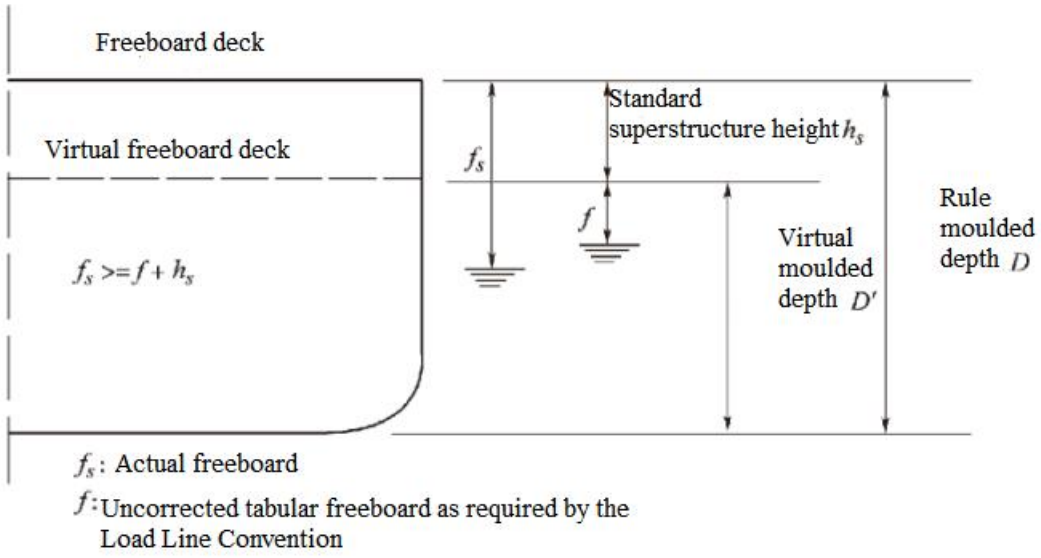

Figure 2.17.1.8

2.17.2 Design pressure head

2.17.2.1 The design pressure head h for end bulkheads of exposed superstructures and boundary bulkheads (end and side bulkheads) of deckhouses is to be obtained as follows and not less than the minimum value in Table 2.17.2.1:

$$h = \alpha\delta(\beta\lambda - \gamma) \quad \text{m}$$

where: α, β, λ and δ — coefficients, to be determined respectively according to 2.17.2.2, 2.17.2.3, 2.17.2.4 and 2.17.2.5 of this Section;

γ — vertical distance, in m, measured from summer load waterline to mid-span of stiffener or mid-point of panel.

Table 2.17.2.1

Length of ship L (m)	Design pressure head h_{min} (m)	
	Lowest tier of unprotected fronts	Elsewhere
$L \leq 50$	3.0	1.5
$50 < L < 250$	$0.01L + 2.5$	$0.005L + 1.25$
$L \geq 250$	5.0	2.5

2.17.2.2 Coefficient α is to be determined as follows:

$\alpha = 0.0083L_1 + 2.0$, lowest tier of unprotected fronts

$\alpha = 0.0083L_1 + 1.0$, second tier of unprotected fronts

$\alpha = 0.0067L_1 + 0.5$, third tier of unprotected fronts and above, protected fronts and sides of all tiers

$\alpha = 0.001L_1 - 0.8\,(X/L) + 0.7$, aft ends of all tiers where aft of amidships

$\alpha = 0.001L_1 - 0.4\,(X/L) + 0.5$, aft ends of all tiers where forward of amidships

where: L, L_1 — length of ship, in m; L_1 need not be taken greater than 300 m;

X — distance, in m, between bulkhead considered and A.P. When determining sides of a deckhouse, the deckhouse is to be subdivided into parts of approximately equal

length, not exceeding 0.15L each and X is to be taken as the distance between A.P. and the centre of each part considered.

2.17.2.3 Coefficient β is to be determined as follows:

$$\beta = 1.0 + \left(\frac{X/L - 0.45}{C_b + 0.2} \right)^2 \text{, for } X/L \le 0.45$$

$$\beta = 1.0 + 1.5\left(\frac{X/L - 0.45}{C_b + 0.2} \right)^2 \text{, for } X/L > 0.45$$

where: L — length of ship, in m;

X — see 2.17.2.2;

C_b — block coefficient, where $C_b < 0.6$, to be taken as 0.6; where $C_b > 0.8$, to be taken as 0.8; where the aft end bulkhead of the superstructure is forward of amidships, C_b used in determining the value β for the aft end bulkhead is not to be taken as less than 0.8.

2.17.2.4 Coefficient λ is to be determined as follows:

$$\lambda = \frac{L}{10} e^{-L/300} - [1 - (\frac{L}{150})^2] \quad \text{for } L < 150 \text{ m}$$

$$\lambda = \frac{L}{10} e^{-L/300} \quad \text{for } 150 \text{ m} \le L < 300 \text{ m}$$

$$\lambda = 11.03 \quad \text{for } L \ge 300 \text{ m}$$

where: L — length of ship, in m.

2.17.2.5 Coefficient δ is to be determined as follows:

$$\delta = 0.7 \frac{b}{B_1} + 0.3 \text{, and not less than 0.475}$$

where: b — breadth of deckhouse at the position considered, in m;

B_1— actual maximum breadth of ship on the exposed weather deck at the position considered, in m.

For exposed parts of superstructures, machinery casings and deckhouses protecting pump room openings, δ is to be taken as 1.

2.17.3 End bulkheads of superstructures and boundary bulkheads of deckhouses

2.17.3.1 The thickness t of end bulkhead plating of superstructures and boundary bulkhead plating of deckhouses is not to be less than:

$$t = 3s\sqrt{hK} \quad \text{mm}$$

The minimum thickness of the plate, t_{min}, is to comply with the following requirements:

If $L_1 \ge 65$ m: $t = (0.01L_1 + 5.0)\sqrt{K}$ mm, for lowest tier

$$t = (0.01L_1 + 4.0)\sqrt{K} \text{ mm, for upper tiers, and not less than 5 mm}$$

If $L_1 < 65$ m: $t_{min} = 5.0$ mm, for the lowest unprotected front

$t_{min} = 4.0$ mm ,for all other cases

where: s — spacing of stiffeners, in m;

h — design pressure head, in m, to be calculated according to 2.17.2 of this Section;

L_1 — length of ship, in m, L_1 need not be taken greater than 300 m;

K — material factor.

2.17.3.2 The section modulus W of end bulkhead stiffeners of superstructures and boundary bulkhead stiffeners of deckhouses is not to be less than:

$$W=3.5shl^2K \quad \text{cm}^3$$

where: s — spacing of stiffeners, in m;

l — span of stiffener, in m; to be taken as height of deckhouse, but not less than 2.0 m in any case;

h — calculated pressure head, in m, to be obtained according to 2.17.2 of this Section;

K — material factor.

Except as required in 2.17.3.3 and 2.17.3.4 of this Section, the end of stiffeners of enclosures of the deckhouse may not be fitted with brackets, provided that the webs of stiffeners are welded to the deck effectively. The section modulus of house side stiffeners need not be greater than that of side frames on the deck situated directly below, taking account of spacing and span.

2.17.3.3 The ends of following stiffeners are to be bracketed or connected by equivalent arrangements. The scantlings of brackets are to be determined according to the relevant provisions of 1.2.6 of this PART:

(1) Front stiffeners of the lowest tier;

(2) Front stiffeners of upper tiers in ships over 150 m in length;

(3) Side stiffeners of single tier deckhouse;

(4) Aft stiffeners of the lowest aft deckhouse;

(5) Side stiffeners of upper deckhouses when the length of ship is greater than 150 m, side stiffeners of the lowest deckhouse if two or more tiers of deckhouses are fitted; where such stiffeners are not bracketed but directly welded to the deck, their section modulus is to be increased by 20%.

2.17.3.4 For exposed machinery and pump-room casings, the front stiffeners on amidships casing and all stiffeners on aft end casings which are situated on the deck to which the moulded depth D is measured are to be bracketed at top and bottom. Where such stiffeners are not bracketed but directly welded to the deck, their section modulus is to be increased by 20% above that required for the stiffeners of deckhouses in the corresponding positions. All other stiffeners on exposed machinery and pump-room casings are to be welded to the decks at top and bottom.

2.17.4 Sides of superstructures

2.17.4.1 The side framing of superstructures is to comply with the following requirements:

(1) Where the side shell is framed transversely, the relevant requirements of Section 7 of this Chapter are to be complied with.

(2) Where the sides of superstructures are framed longitudinally and located within the range of 0.3L from A.P. forward the bow, the section modulus of longitudinals is not to be less than:

$$W = 6.5sl^2(0.6+0.167D_1)K \quad \text{cm}^3$$

where: s— spacing of longitudinals, in m;

l — span of longitudinal, in m, not less than 1.5 m;

$D_1 = d + H_b$, in m, not greater than 20 m,

where: H_b— the minimum bow height as required by load line assignment, in m;

d — draught, in m;

K— material factor.

The section modulus of web frames supporting the side longitudinals is not to be less than:

$$W = 8.8Sl^2(0.6 + 0.167D_1)K \qquad \text{cm}^3$$

where: D_1, K — the same as those in the above formula;

S — spacing of web frames, in m;

l — span of web frames, in m.

(3) Where the sides of superstructures are framed longitudinally and located beyond the range of 0.3L from A.P forward the bow, the section modulus of longitudinals is not to be less than:

$$W = 7.5sl^2(0.6 + 0.167D_2)K \quad \text{cm}^3$$

where: s— spacing of longitudinals, in m;

l— span of longitudinal, in m, not less than 1.5 m;

$D_2 = d + H_b$, in m;

where: H_b— the minimum bow height as required by load line assignment, in m;

d — draught, in m;

K— material factor.

The section modulus of web frames supporting the side longitudinals is not to be less than:

$$W = 10Sl^2(0.6 + 0.167D_2)K \qquad \text{cm}^3$$

where: D_2, K — the same as those in the above formula;

S — spacing of web frames, in m;

l — span of web frames, in m.

Where the superstructure is located within the range of 0.4L amidships and contributes to the longitudinal strength, the relevant requirements of 2.2.7, Section 2 of this Chapter are also to be complied with.

2.17.4.2 The side plating of superstructures is to comply with the following requirements:

(1) The thickness t of side plating of forecastles is not to be less than:

$$t = (0.028L + 5.5)\sqrt{\frac{sK}{s_b}} \qquad \text{mm}$$

where: L — length of ship, in m;

s — spacing of frames or longitudinals, in m, to be taken as not less than s_b;

s_b — standard spacing of frames or longitudinals, in m;

K — material factor.

(2) The thickness t of side plating of bridge and poop is not to be less than:

$$t = (0.025L + 5)\sqrt{\frac{sK}{s_b}} \qquad \text{mm}$$

where: L — length of ship, in m;

s — spacing of frames or longitudinals, in m, to be taken as not less than s_b;

s_b — standard spacing of frames or longitudinals, in m;

K — material factor.

2.17.5 Decks

2.17.5.1 The deck framing of superstructures is to comply with the relevant requirements of Section 8 of this Chapter. The deck framing of the forecastle is also to comply with the following requirements:

(1) Within the region forward of 0.075L from F.P., the spacing of deck girders supporting the beams is generally not to be more than 3.5 m, and that of the transverses supporting the deck longitudinals is generally not to be more than 2.5 m;

(2) The web depth of deck girders and transverses is not to be less than twice the depth of cutouts for the passage of beams or longitudinals being supported.

2.17.5.2 The section modulus W of the deck longitudinals or beams of deckhouses is not to be less than:

$$W = 5shl^2K \quad \text{cm}^3, \text{ and not less than } 25s$$

where: s — spacing of deck longitudinals or beams, in m;

l — span of deck longitudinals or beams, in m;

h — design pressure head, in m, to be determined as follows:

0.9 m, for those on first tier deck;

0.6 m, for those on second tier deck;

0.45 m, for those on third tier deck and above;

K — material factor.

2.17.5.3 The scantlings of deck girders and transverses of deckhouses are to be calculated in accordance with the relevant requirements of Section 8 of this Chapter, but the design pressure head is to be as specified in 2.17.5.2 of this Section. The web thickness of girders of deckhouses is not to be less than 1% of their depth plus 2 mm, but not to be less than 4 mm.

2.17.5.4 The thickness t of deck plating of superstructures (except the forecastle) and deckhouses is not to be less than:

$$t = (0.02L + C)\sqrt{\frac{sK}{s_b}} - t_c \quad \text{mm, and not less than 5 mm}$$

where: L — length of ship, in m; not to be taken as greater than 100 m;

s — spacing of deck longitudinals or beams, in m, to be taken as not less than s_b;

s_b — standard spacing of deck longitudinals or beams, in m;

C — coefficient, to be taken as follows:

5.5, for the first tier deck;

5.0, for the second tier deck;

4.5, for the third tier deck and above;

t_c — t_c = 1 for decks of dry spaces within superstructures or deckhouses; t_c = 0 in other cases;

K — material factor.

2.17.5.5 The thickness t of forecastle deck plating is not to be less than:

$$t = (0.02L + 6)\sqrt{\frac{sK}{s_b}} \quad \text{mm}$$

where: L — length of ship, in m;

s — spacing of deck longitudinals or beams, in m, to be taken as not less than s_b;

s_b — standard spacing of deck longitudinals or beams, in m;

K — material factor.

2.17.6 Local strengthening of superstructures

2.17.6.1 Web frames or partial bulkheads spaced about 9 m apart are to be fitted within the poop or bridge that have large deckhouses or other erections above, to support side and end bulkheads of the deckhouses.

Appropriate strength members are also to be fitted in other areas under high loading.

2.17.6.2 The web frames or partial bulkheads within superstructures are to be arranged, where practicable, in line with the watertight bulkheads or other strength members below.

2.17.6.3 Pillars, diaphragms, bulkheads or other strength members are to be arranged under the ends of superstructures for support.

2.17.6.4 To reduce stress concentration in main hull structure in way of ends of superstructures which are flush with ship's side, the side plating of the superstructures is to extend beyond their ends and the height of the side plating is to be gradually reduced to that of the sheer strake in a smooth transition (free edges of extension plating generally in an oval shape with horizontal axis, see Figure 2.17.6.4). This plating is to be supported by stiffened brackets and to be efficiently stiffened at the upper edge by a face plate having the same thickness as the extension plating and a breadth not less than 10 times its thickness. The extension plating is to comply with the following requirements:

(1) For end bulkheads of superstructures situated within 0.5L amidships, the length of the extension plating is not to be less than 1.5 times that of the superstructure and its thickness is to be increased by 25%;

(2) For end bulkheads of superstructures situated within 0.2L from the ship's ends, the length of the extension plating is not to be less than the height of the superstructure and its thickness need not be increased;

(3) For end bulkheads of superstructures situated between 0.2L and 0.25L from the ship's ends, the increased length and thickness of the extension plating is to be obtained by interpolation.

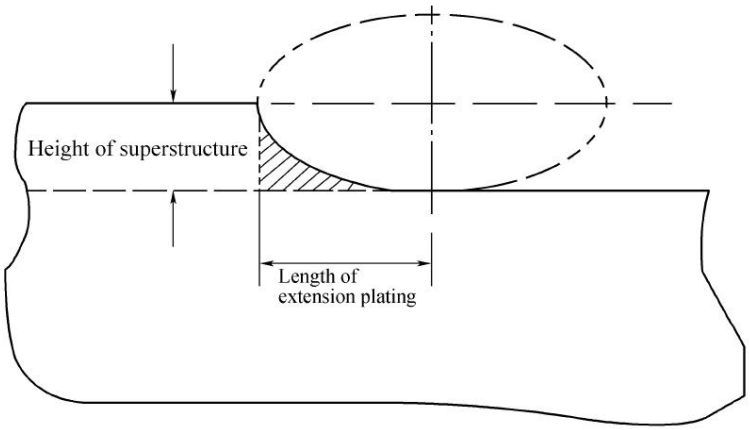

Figure 2.17.6.4

2.17.6.5 The thickness of the upper deck stringer plate and the sheer strake is to be increased at the ends of the superstructure from at least two frame spaces inside the superstructure to two frame spaces beyond the extension of side plating (see Figure 2.17.6.5) in accordance with the following requirements:

(1) Where the end bulkheads of the superstructure are situated within 0.5*L* amidships, the thickness of stringer plates and sheer strakes is to be increased by 20%;

(2) Where the end bulkheads of the superstructure are situated within 0.2*L* from the ship's ends, the thickness of stringer plates and sheer strakes need not be increased;

(3) Where the end bulkheads of the superstructure are situated between 0.2*L* and 0.25*L* from the ship's ends, the increased thickness of stringer plates and sheer strakes is to be obtained by interpolation.

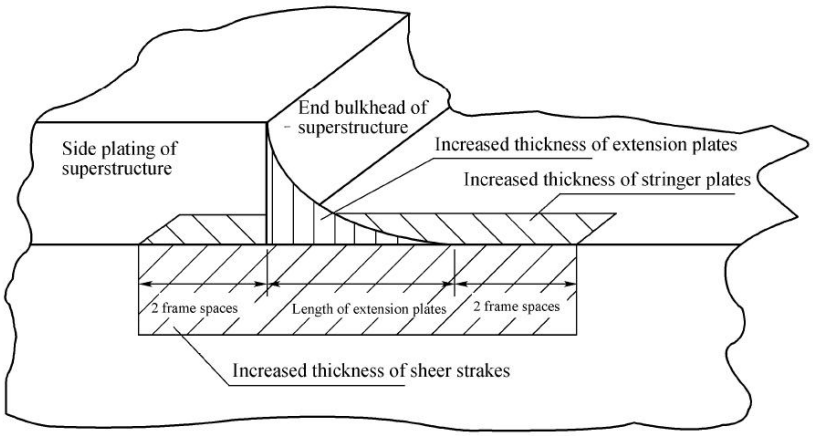

Figure 2.17.6.5

2.17.7 Local strengthening of deckhouses

2.17.7.1 Adequate support under the ends of deckhouses is to be provided in the form of pillars, diaphragms, bulkheads or other strength members. At the corners of houses and in way of supporting structures, attention is to be given to the connection to the deck, and inserts or equivalent arrangements are generally to be fitted.

2.17.7.2 All openings cut in the sides of long deckhouses are to be adequately strengthened and have well rounded corners. Continuous coamings with adequate height are to be fitted below and above doors or similar openings. House tops are to be strengthened in way of boats and davits. Special care is to be taken to minimize the size and number of openings in the side bulkheads in the region of the ends of deckhouses within 0.5*L* amidships.

2.17.7.3 The sides and ends of the long deckhouses on the lowest tier deck are generally to be strengthened by partial bulkheads or vertical webs spaced about 9 m apart, and these stiffening members are, as far as practicable, to be arranged in line with the strengthening members within the 'tween deck space below the deckhouse.

2.17.8 Raised quarterdecks

2.17.8.1 The scantlings of the main frames in way of the raised quarter deck are to be determined according to the requirements of Section 7 of this Chapter. In this case the span of the frame is to be measured to the raised quarter deck.

The scantlings of the deck frames in way of the raised quarter deck are to be determined in accordance with the relevant requirements for the strength deck as specified in Section 8 of this Chapter.

The thickness of the raised quarter deck sheer strake is to be determined according to the requirements of Section 3 of this Chapter, and the thickness of deck plating is to be determined in accordance with the relevant requirements for strength deck as specified in Section 4 of this Chapter. In such cases the moulded depth is to be taken as that at the raised quarter deck.

The thickness of break bulkheads and the scantlings of stiffeners are to be determined in accordance with the requirements for end bulkheads of corresponding superstructures.

2.17.8.2 Strengthening at the break within 0.5*L* amidships

(1) For $L < 65$ m, the strength deck stringer plate and the raised quarter deck stringer plate are to extend respectively for 3 or 4 frame spaces on either side of the break bulkhead and are to be gradually tapered off;

(2) For $L \geq 65$ m, the upper and raised deck plating at the break is to overlap for 2 or 3 frame spaces, and in this case the stringer plates of both decks are to extend forward for 2 or 3 frame spaces beyond the end of overlapped plating. Vertical diaphragm plates spaced not more than 1.5 m apart in parallel with the longitudinal centreline are to be fitted between the overlapped deck plating. The thickness of the diaphragm plates is to be the same as that of the break bulkhead plating, and the diaphragms are to be efficiently stiffened and their free edges are to be flanged or provided with a face plate.

2.17.8.3 Where the break is located outside of 0.5*L* amidships, the strength deck stringer plate is to extend for 3 frame spaces beyond the break and is to be gradually tapered off.

2.17.8.4 The sheer strake is to be increased in thickness by 30% for a distance of 3 to 5 frame spaces on either side of the break bulkhead. Where a raised quarter deck is connected to a long bridge, the sheer strake of side plating within the raised quarter deck area is to be increased in thickness by 25% for a distance of at least 2 frame spaces on either side of the break, and the side plating of the bridge is to be gradually tapered in a curve line from the end of the bridge deck stringer plate into the sheer strake of side plating within raised quarter deck area over a length more than 1.5 times the height of the bridge above the raised quarter deck.

2.17.9 Machinery casings

2.17.9.1 Machinery space openings in the exposed deck are to be protected by strong steel casings. Machinery casings situated on the freeboard or raised quarter deck are to be enclosed in the superstructures or deckhouses so far as practicable.

2.17.9.2 Doors in machinery casings are to be of steel and rigid construction, and are to be capable of being operated from both sides.

2.17.9.3 The scantlings of boundary bulkheads of exposed casings are to be determined in accordance with the requirements for those of the deckhouses in the corresponding positions.

2.17.9.4 The scantlings of boundary bulkheads of non-exposed casings are to comply with the following requirements:

(1) The minimum thickness of boundary bulkheads of the casings is not to be less than 6.5 mm in way of cargo spaces and not to be less than 5 mm in way of accommodation spaces;

(2) The section modulus *W* of the stiffeners of boundary bulkheads of the casings is not to be less than that obtained from the following formula:

$$W = 8slK \quad \text{cm}^3$$

where: s — spacing of stiffeners, in m;

l — span of stiffener, in m;

K— material factor.

For ships of 65 m or over in length, the depth of stiffeners is not to be less than 60 mm.

2.17.9.5 Where casing stiffeners support the deck transverses or girders or where they are in line with pillars below, they are to be suitably strengthened.

2.17.9.6 Where the casing sides act as girders supporting decks above, the openings for doors, windows, etc., in the sides are to be effectively strengthened. Particular attention is to be paid to stiffening where the casing supports the funnel or exhaust uptakes.

2.17.10 Breakwater

2.17.10.1 The load under consideration is to be determined with the requirements for fronts of superstructures in 2.17.2 of this Section as reference.

2.17.10.2 The thickness of breakwater plating and the scantlings of breakwater stiffeners are to be determined according to 2.17.3 of this Section.

2.17.10.3 The scantlings of main members (horizontal girders and vertical webs) supporting breakwaters are to be determined by direct calculations, and the permissible stress is as follows:

$$[\sigma_e] = \sqrt{\sigma^2 + 3\tau^2} = 235/K \quad \text{N/mm}^2$$

where: K — material factor.

Section 18 HELICOPTER DECKS

2.18.1 General requirements

2.18.1.1 This Section applies to all ships fitted with areas and facilities for normal takeoff and landing of helicopters.

2.18.1.2 Helicopter decks covered by this Section mean helicopter deck structure only.

2.18.1.3 For helicopter deck connected by bolts and splice other than welding, special consideration is to be given to the requirements for structural strength.

2.18.2 Plans and documents

2.18.2.1 The following plans and documents are to be submitted for approval:

(1) Detailed arrangement of helicopter deck, including overall dimensions, landing area/securing area, if any;

(2) Structural plan for helicopter deck (appropriate strength calculations are submitted for information).

2.18.2.2 Loading manual is to include information on models and parameters of helicopters to be used, including maximum takeoff weight, overall length of helicopter (including rotation of rotor), size of wheel print and tracking width.

2.18.3 Arrangement of helicopter deck

2.18.3.1 The arrangement and construction of helicopter deck is to meet the applicable standards accepted by the flag Administration, such as the annex to IMO MSC/Circ.895 and MSC.1/Circ.1524—Recommendation on Helicopter Landing Areas on Ro-Ro Passenger Ships, International Chamber of Shipping (ICS)- Guide to Helicopter/Ship Operations, International Aeronautical and Maritime Search and Rescue Manual (IAMSAR) and Offshore Helicopter Landing Areas-Guidance on Standards (CAP437).

2.18.4 Design conditions

2.18.4.1 The supporting structure of the helicopter platform is to be designed to the following three conditions: overall distributed loading, helicopter landing impact loading and stowed helicopter loading (if provisions are made to accommodate the helicopter secured to the deck in a predetermined position):

(1) Overall distributed loading:

① a minimum distributed loading of 2 kN/m^2 is to be taken over the entire helicopter deck.

(2) Helicopter landing impact loading: Combination of the following loads is to be taken into account:

① for normal landing, vertical impact loading P_H = 1.5P (P being the maximum takeoff weight), uniformly distributed on both wheel prints when landing (landing of both wheels at the same time is generally assumed). Where no data on actual size of wheel prints are available, the size of each print may be taken as a square area of 0.30 m × 0.30 m. The structural members are to be designed according to the worst landing position with regard to forces acting on them.

Where the upper deck of a superstructure or deckhouse is used as a helicopter platform deck and the spaces below are normally manned (control room, quarters, etc.), the above vertical impact loading P_H = 1.75P;

② the structural weight of the helicopter deck;

③ where necessary, a uniformly distributed loading of 0.5 kN/m^2, representing wet snow, ice or other environmental loading, is to be considered.

(3) Stowed helicopter loading: Combination of the following loads is to be taken into account:

① wheel loading at maximum takeoff weight, with landing area being assumed as that for helicopter landing impact loading;

② the structural weight of the helicopter deck;

③ where necessary, a uniformly distributed loading of 0.5 kN/m^2, representing wet snow, ice or other environmental loading, is to be considered;

④ in addition, where stowage of helicopters is possible, the inertial forces of helicopter and helicopter platform due to ship's motion under corresponding environmental conditions are to be considered. If no proper data are available, both the horizontal and vertical inertial forces may be taken as 0.5 times the loading corresponding to the weight of helicopter and helicopter platform structure.

2.18.4.2 For helicopters fitted with landing gear other than wheels, the landing area is to be determined according to the data provided by manufacturers.

2.18.5 Helicopter deck plating

2.18.5.1 The initial plate thickness of the helicopter deck may be calculated in accordance with

2.21.2.1(1) of this Chapter, with loading being the wheel impact loading required for the above design conditions.

2.18.5.2 Where the helicopter deck is the strength deck within 0.4L amidships, the wheel impact loading obtained according to 2.18.5.1 of this Section is to be multiplied by a factor of 1.18. This factor is linearly reduced to 1.00 within 0.4L amidships aft or forward along ship's length.

2.18.5.3 The helicopter deck plate thickness is to be based on the initial thickness calculated according to 2.18.4.1 or 2.18.4.2, and is to comply with the strength verification of the entire helicopter deck structure by direct calculation.

2.18.5.4 Hatch covers used as helicopter deck are to comply with this Section and in addition, Section 20 of this Chapter.

2.18.5.5 Where the helicopter deck forms part of a weather deck or other decks, the scantlings are not to be less than those required for decks in the same position.

2.18.6 Strength verification by direct calculation

2.18.6.1 Direct calculation of helicopter deck structure is to be preformed by 3-dimensional finite element structural analysis, and recognized programs and structural idealization methods are to be used.

2.18.6.2 The permissible bending stress [σ], shear stress [τ] of helicopter deck plating, deck framing and their supporting structure and the permissible stress [σ_{cb}] of compressed components are as follows:

(1) The permissible bending stress [σ] is to be determined according to Table 2.18.6.2.

Permissible Bending Stress [σ] **Table 2.18.6.2**

Structural member / Design condition	Deck plating	Longitudinals, transverses and other secondary deck members	Girders, web beams and other main deck members Stanchions, supports and other truss supports of platform
Overall distributed loading	$0.6R_{eH}$ ③	$0.6R_{eH}$	$0.6R_{eH}$ ①
Helicopter landing impact loading	R_{eH} ②	R_{eH}	$0.9R_{eH}$ ①
Stowed helicopter loading	R_{eH}	$0.9R_{eH}$	$0.9R_{eH}$ ①

Notes: R_{eH} — yield stress of material, in N/mm^2; for aluminium alloy, taken as $R_{p0.2}$, see Section 3, Chapter 1 of this PART.

① Components under axial compression are to be checked to the lesser of permissible bending stress and permissible critical buckling stress.

② For helicopter landing impact loading, where the stress of helicopter deck plating is obtained according to a four-sides supported plate subjected to vertically distributed loading, the permissible stress may be taken as 1.1 R_{eH}.

③ For overall distributed loading, the helicopter deck plating thickness is not to be less than the minimum thickness required by 2.18.5 and the Rules.

(2) Permissible shear stress [τ]: $[\tau] = [\sigma] / \sqrt{3}$.

(3) Permissible compressive stress [σ_{cb}] is to be calculated according to 2.2.7.5(1) and 2.2.7.6 of this Chapter.

2.18.6.3 The value of the permissible bending stress for framing and girders of strength deck used as helicopter deck is to be multiplied by a reduction factor in Table 2.18.6.3.

Reduction Factor **Table 2.18.6.3**

Location of helicopter deck	Reduction factor	Location of helicopter deck	Reduction factor

Area between A.P. and F.P.	Linear interpolation		

Section 19 BULWARKS AND GUARDRAILS

2.19.1 General requirements

2.19.1.1 Guardrails or bulwarks are to be fitted around all exposed decks. The height of the bulwarks or guardrails is to be at least 1 m from the deck, provided that where this height would interfere with the normal operation of the ship, a lesser height may be approved, if the Administration is satisfied that adequate protection is provided.

2.19.1.2 The ship designed for the carriage of timber deck cargoes is to be fitted either with permanent bulwarks at least 1 m in height, specially stiffened on the upper edge and supported by strong bulwark stays attached to the deck and provided with necessary freeing ports, or with efficient rails of the same height and of specially strong construction.

2.19.2 Bulwarks

2.19.2.1 The plating thickness of bulwarks on freeboard decks is not to be less than 5 mm for ships having a length less than 65 m and not to be less than 6 mm for ships having a length equal to 65 m or over. The plating thickness of bulwarks elsewhere may be suitably reduced.

2.19.2.2 The top edge of bulwarks is to be stiffened by a flat bar or profile steel.

2.19.2.3 Bulwarks are to be supported by stays with flange or face plate from the deck in line with the beams or beam webs. Where the frame spacing does not exceed 620 mm, the spacing of stays is not to exceed 3 frame spaces. Where the frame spacing exceeds 620 mm or where the ship is intended for the carriage of timber deck cargoes, the spacing of stays is not to be greater than 2 frame spaces. Where the bulwarks on the forecastle deck have a great flare, stays are to be fitted at every frame.

2.19.2.4 The section modulus W at the bottom of bulwark stays is not to be less than that obtained from the following formula:

$$W = (30 + 0.45L)SH^2K \quad \text{cm}^3$$

where: S— spacing of stays, in m;

L— length of ship, in m, not to be taken as greater than 100 m;

H— height of bulwark, in m;

K— material factor.

Where the flange of the stay is not welded to the deck, such a flange is not to be considered for the section modulus.

2.19.2.5 Bulwarks are to be adequately strengthened in way of mast shrouds or eyeplates for cargo gear and in way of fairleaders.

2.19.2.6 Where bulwarks are cut to form a gangway or other openings, stays of increased strength are to be fitted at the ends of the openings. Bulwarks are not to be cut for gangway or other openings near the breaks of superstructures.

2.19.2.7 Bulwarks are as far as practicable not to be welded to the sheer strake amidships so as to ensure their freedom from the longitudinal bending of the hull.

2.19.3 Guardrails

2.19.3.1 Guardrails fitted on superstructure and freeboard decks are to have at least three courses. The opening below the lowest course of the guardrails is not to exceed 230 mm. The other courses are to be not more than 380 mm apart. In the case of ships with rounded gunwales the guardrail supports are to be placed on the flat of the deck. In other locations, guardrails with at least two courses are to be fitted.

2.19.3.2 Where external glass balustrades are fitted, reference may be made to relevant requirements of Section 8, Chapter 9 of this PART.

Section 20 HATCHWAYS AND HATCH COVERS

2.20.1 General requirements

2.20.1.1 In addition to the requirements of this Section, exposed hatchways and hatch covers are to comply with the relevant requirements of the Amendments to Annex I to Annex B of the Protocol of 1988 Relating to the International Convention on Load Lines, 1966.

2.20.1.2 The structural scantlings of non-exposed hatch covers may be determined according to the relevant requirements of this Section, depending on their structural configuration and with only permissible cargo loads being taken into account.

2.20.1.3 The scantlings of steel hatch covers for deep tanks may be determined according to the relevant requirements of this Section and depending on the position of hatch covers, but in no case are to be less than those required in Section 13 of this Chapter for deep tank deck and its framing.

2.20.1.4 Where wheeled vehicles are to be stowed on hatch covers or used for cargo handling, the scantlings of hatch covers are also to comply with the requirements for vehicle deck in Section 21 of this Chapter.

2.20.1.5 The scantlings of hatch covers used as helicopter deck are also to comply with the requirements for helicopter decks in Section 18 of this Chapter.

2.20.1.6 Except as otherwise provided, the width of the attached plating of hatch cover stiffeners and girders is to be determined according to 1.2.2 of Section 2, Chapter 1 of this PART. However, the areas of stiffeners are not to be included in the area of the attached plating of girders.

2.20.1.7 For the hatch covers on the lower deck within cargo holds, the strength is to be checked according to the requirements of 2.20.3.

2.20.1.8 Height of hatch coamings

(1) at Position 1, the height is not to be less than 600 mm;

(2) at Position 2, the height is not to be less than 450 mm;

(3) for ships provided with steel weathertight hatch covers, with the consent of the flag State Administration, the height of hatch coamings may be suitably reduced provided that efficient measures have been taken and that the safety of the ship is not impaired;

(4) for hatchways on unexposed freeboard decks or exposed superstructure decks, hatchway coamings with a suitable height may be provided depending upon the position of the hatchways and the protection necessitated by such hatchways.

2.20.1.9 Hatch cover types

(1) Single skin cover

A hatch cover made of steel or equivalent material that is designed to comply with ICLL Regulation 16. The cover has continuous top and side plating, but is open underneath with the stiffening structure exposed. The cover is to be weathertight and fitted with gaskets and clamping devices unless specifically exempted from such fittings.

(2) Double skin cover

A hatch cover as above but with continuous bottom plating such that all the stiffening structure and internals are protected from the environment.

(3) Pontoon type cover

A special type of portable cover, secured weathertight by tarpaulins and battening devices. Such covers are to be designed in accordance with ICLL Regulation 15.

Note: Modern designs of lift-away hatch covers are in many cases called pontoon covers. This definition does not fit to the (3) above. Modern lift-away hatch covers are to fall into one of the two categories of single skin covers and double skin covers.

2.20.2 Weathertight steel hatch covers

2.20.2.1 General requirements

(1) These requirements apply to all ships except CSR bulk carriers, and are for all cargo hatch covers and coamings on exposed decks. As specified in this Section, parts of the requirements are for some specific ship types as categorized below:

① Type-1 ships, including all ships except bulk carriers, self-unloading bulk carriers, ore carriers and combination carriers.

② Type-2 ships, including all bulk carriers, self-unloading bulk carriers, ore carriers and combination carriers.

(2) The strength requirements are applicable to hatch covers and hatch coamings of stiffened plate construction and their closing arrangements.

(3) These requirements are applicable to hatch covers and coamings made of steel. The materials of hatch covers and hatch coamings are to meet the relevant requirements of Section 3, Chapter 1 of this PART. The material class I is to be applied for top plate, bottom plate and primary supporting members of hatch covers. Equivalent materials and novel designs subject to approval by CCS.

(4) Primary supporting members and secondary stiffeners of hatch covers are to be continuous over the breadth and length of hatch covers, as far as practical. When this is impractical, sniped end connections are not to be used and appropriate arrangements are to be adopted to provide sufficient load carrying capacity.

The spacing of primary supporting members parallel to the direction of secondary stiffeners is not to exceed 1/3 of the span of primary supporting member. When strength calculation is carried out by FE analysis using plane strain or shell elements, this requirement may be relaxed appropriately.

Secondary stiffeners of hatch coamings are to be continuous over the breadth and length of hatch coamings.

(5) Unless stipulated otherwise, the thickness t in these requirements is net thickness.

The net thicknesses are the member thicknesses necessary to obtain the minimum net scantlings required by 2.20.2.3 to 2.20.2.6 and 2.20.2.8 of this Section.

The required gross thickness is obtained by adding the corrosion addition t_s, given in 2.20.2.10 of this Section, to the net thickness t_s.

Strength calculations using FEM are to be performed with net scantlings.

2.20.2.2 Hatch cover and coaming load model

The structural strength evaluation of hatch covers and hatch coamings is to be carried out using the design loads defined as follows:

Definitions:

L = length of ship, in m;

L_L = load line length, in m;

x = longitudinal distance measured from midpoint of structural member to the aft end of L or L_L, in m;

$D_{\min}$ = the least moulded depth, in m, as defined in Regulation 3 of ICLL Annex I;

h_N = standard superstructure height, in m, to be calculated as follows:

$$h_N = 1.05 + 0.01L_L \text{, and} 1.8 \le h_N \le 2.3 .$$

(1) Vertical weather design load

The pressure p_H, in kN/m², on the hatch cover panel is given by ICLL. This may be taken from Table 2.20.2.2(1). The vertical weather design load is not to be combined with cargo loads in 2.20.2.2(3) and (4).

For Position 1 and Position 2, see Figure 2.20.2.2(1).

Where an increased freeboard is assigned, the design load for hatch covers on the actual freeboard deck may be as required for a superstructure deck, provided that the summer freeboard is such that the resulting draught will not be greater than that corresponding to the minimum freeboard calculated from an assumed freeboard deck situated at a distance at least equal to the standard superstructure height h_N below the actual freeboard deck, see Figure 2.20.2.2(2).

Figure 2.20.2.2(2) Positions 1 and 2 for an Increased Freeboard

(2) Horizontal weather design load

① General horizontal weather design load

The horizontal weather design load p_A , in kN/m^2, for determining the scantlings of outer edge girders (skirt plates) of weather deck hatch covers and of hatch coamings is to be calculated by the following formula:

$$p_A = ac(bfc_L - z) \quad \text{kN/m}^2$$

where: $f = \frac{L}{25} + 4.1$, for L< 90 m;

$f = 10.75 - \left(\frac{300 - L}{100}\right)^{1.5}$, for $90\text{m} \le L < 300\text{m}$;

$f = 10.75$, for $300\text{m} \le L < 350\text{m}$;

$f = 10.75 - \left(\frac{L - 350}{150}\right)^{1.5}$, for $350\text{m} \le L \le 500\text{m}$;

$c_L = \sqrt{\frac{L}{90}}$, for $L < 90$ m;

$c_L = 1$, for $L \ge 90\text{m}$;

$a = 20 + \frac{L_1}{12}$, for unprotected front coamings and hatch cover skirt plates;

$a = 10 + \frac{L_1}{12}$, for unprotected front coamings and hatch cover skirt plates, where the distance from the actual freeboard deck to the summer load line exceeds the minimum non-corrected tabular freeboard according to ICLL by at least one standard superstructure height;

$a = 5 + \frac{L_1}{15}$, for side and protected front coamings and hatch cover skirt plates;

$a = 7 + \frac{L_1}{100} - \frac{8x'}{L}$, for aft ends of coamings and aft hatch cover skirt plates abaft amidships;

$a = 5 + \frac{L_1}{100} - \frac{4x'}{L}$, for aft ends of coamings and aft hatch cover skirt plates forward of amidships;

L_1=L, but need not be taken as greater than 300 m;

$b = 1.0 + \left(\frac{\frac{x'}{L} - 0.45}{C_b + 0.2}\right)^2$, for $\frac{x'}{L} < 0.45$;

$b = 1.0 + 1.5\left(\frac{\frac{x'}{L} - 0.45}{C_b + 0.2}\right)^2$, for $\frac{x'}{L} \ge 0.45$;

C_b — block coefficient, $0.6 \le C_b \le 0.8$, when determining scantlings of aft ends of coamings and aft hatch cover skirt plates forward of amidships, C_b need not be taken less than 0.8;

x' — distance in m, between the transverse coaming or hatch cover skirt plate considered and aft end of the length L . For side coamings or side hatch cover skirt plates, the side is to be subdivided into parts of approximately equal length, not exceeding 0.15 L each, and "x" is to be taken as the distance between aft end of the length L and the centre of each part considered;

z — vertical distance, in m, from the summer load line to the midpoint of stiffener span, or to the middle of the plate field;

$c = 0.3 + 0.7\frac{b'}{B'}$, the $\frac{b'}{B'}$ is not to be less than 0.25;

b' — breadth of coaming, in m, at the position considered;

B' —actual maximum breadth of ship, in m, on the exposed weather deck at the position considered.

The horizontal design load is not to be taken less than the minimum values given in Table 2.20.2.2(2).

Minimum Horizontal Design Load P_{Amin} Table 2.20.2.2(2)

L	P_{Amin} kN/m²	
	Unprotected fronts	elsewhere
≤ 50m	30	15
> 50m	$25+\frac{L}{10}$	$12.5+\frac{L}{20}$
< 250m		
≥ 250m	50	25

② Horizontal weather design load applicable to coamings of Type-2 ships

The pressure P_{coam}, in kN/m², on the No. 1 forward transverse hatch coaming is given by:

$P_{coam} = 220$ kN/m², when a forecastle is fitted in accordance with Section 13, Chapter 8 of this PART;

$P_{coam} = 290$ kN/m² in the other cases;

The pressure P_{coam}, in kN/m² , on the other coamings is given by:

$P_{coam} = 220$ kN/m²

Note: The horizontal weather design loads p_A and P_{coam} need not be included in the direct strength calculation of the hatch cover, unless it is utilized for the design of substructures of horizontal support according to 2.20.2.9(2)③.

(3) Cargo loads

① Distributed loads

The uniform cargo load on hatch covers due to cargo loads p_L, resulting from heave and pitch (i.e. ship in upright condition) is to be determined according to the following formula:

$$p_L = p_C(1 + a_V) \quad \text{kN/m}^2$$

where: p_C — uniform cargo load, in kN/m²;

a_V — vertical acceleration addition as follows:

$a_V = Fm$;

$F = \frac{0.11 v_0}{\sqrt{L}}$;

$m = m_0 - 5(m_0 - 1)\frac{x}{L}$ for $0 \le \frac{x}{L} \le 0.2$;

$m = 1.0$ for $0.2 < \frac{x}{L} \le 0.7$;

$m = 1 + \frac{m_0 + 1}{0.3}\left[\frac{x}{L} - 0.7\right]$ for $0.7 < \frac{x}{L} \le 1.0$;

$m_0 = 1.5 + F$;

v_0 — maximum speed at summer load line draught, is not to be taken less than $\sqrt{L}$, in kn.

② Point loads

The load P, in kN, due to a concentrated force P_S, in kN, except for container load, resulting from heave and pitch (i.e. ship in upright condition) is to be determined as follows:

$$P = P_S(1 + a_V) \quad \text{kN}$$

(4) Container loads

① The loads defined in ② to ④ are to be applied where containers are stowed on the hatch cover.

② Corner loads for ship in upright condition

The load P, in kN, applied at each corner of a container stack, and resulting from heave and pitch (i.e. ship in upright condition) is to be determined as follows:

$$P = 9.81\frac{M}{4}(1 + a_V) \quad \text{kN}$$

where: a_V — vertical acceleration addition according to (3)①;

M — maximum designed mass of container stack, in t.

③ Corner loads for ship in heel condition

Where containers are stowed on hatch covers, the loads due to heave, pitch and the ship's rolling motion are to be determined as follows (see Figure 2.20.2.2(4)):

$$A_z = 9.81\frac{M}{2}(1 + a_V)\left(0.45 - 0.42\frac{h_m}{b}\right) \quad \text{kN}$$

$$B_z = 9.81\frac{M}{2}(1 + a_V)\left(0.45 + 0.42\frac{h_m}{b}\right) \quad \text{kN}$$

$$B_y = 2.4M \quad \text{kN}$$

where:

a_V — vertical acceleration addition according to 2.20.2.2(3);

M — maximum designed mass of container stack, in t;

h_m — designed height of centre of gravity of stack above hatch cover top, in m, may be calculated as weighted mean value of the stack, where the centre of gravity of

each tier is assumed to be located at the centre of each container, $=\sum(z_i \cdot W_i)/M$;

z_i — distance from hatch cover top to the centre of *i*th container, in m;

W_i — mass of *i*th container, in t;

b — distance between foot points, in m;

A_z, B_z — support forces in *z*-direction at the forward and aft stack corners;

B_y — support forces in *y*-direction at the forward and aft stack corners.

Values of A_z and B_z applied for the hatch cover strength evaluation are to be shown in the drawings of the hatch covers.

Note: It is recommended that container loads as calculated above are considered as limit for foot point loads of container stacks in the calculations of cargo securing (container lashing).

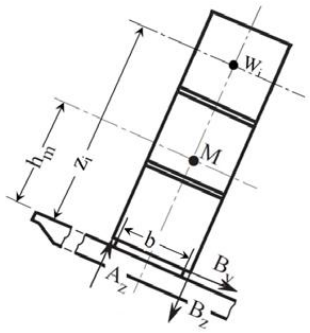

Figure 2.20.2.2(4)

④ Load cases with partial loading

The load cases in ② and ③ above are also to be considered for partial non-homogeneous loading which may occur in practice, e.g. where specified container stack places are empty. For each hatch cover, the heel directions, as shown in Table 2.20.2.2(4), are to be considered. The load case of partial loading of container hatch covers may be evaluated using a simplified approach, where the hatch cover is loaded without the outermost stacks that are located completely on the hatch cover. If there are additional stacks that are supported partially by the hatch cover and partially by container stanchions then the loads from these stacks may be neglected, refer to Table 2.20.2.2(4) Partial loading of container hatch covers.

In addition, the case where only the stack places supported partially by the hatch cover and partially by container stanchions are left empty is to be assessed in order to consider the maximum loads in the vertical hatch cover supports.

It may be necessary to also consider partial load cases where more or different container stack places are left empty. Therefore, CCS may require that additional partial load cases other than those in Table 2.20.2.2(4) be considered.

Partial loading of container hatch covers **Table 2.20.2.2(4)**

Heel direction	←	→

Heel direction	←	→
Hatch covers supported by the longitudinal hatch coaming with all container stacks located completely on the hatch cover		Hatch covers supported by the longitudinal hatch coaming with the outermost container stack supported partially by the hatch cover and partially by container stanchions		Hatch covers not supported by the longitudinal hatch coaming (center hatch covers)		
⑤ Mixed stowage of 20’ and 40’ containers on hatch cover

In the case of mixed stowage (20'+40' container combined stack), the foot point forces at the fore and aft end of the hatch cover are not to be higher than resulting from the design stack weight for 40’ containers, and the foot point forces at the middle of the cover are not to be higher than resulting from the design stack weight for 20’ containers.

(5) Hatch covers, which in addition to the loads according to (1) to (4) above are loaded in the ship’s transverse direction by forces due to elastic deformations of the ship’s hull, are to be designed such that the sum of stresses does not exceed the allowable value given in 2.20.2.5.

2.20.2.3 The net structural scantling of weathertight steel hatch covers is to be in compliance with the following requirements:

(1) Local net plate thickness

The local net plate thickness of the hatch cover top plating is not to be less than that obtained from the following formulae, and not less than 6 mm:

$$t = 0.0158 F_p s \sqrt{\frac{p}{0.95 R_{eH}}} \quad \text{mm}$$

$$t = 0.01 s \quad \text{mm}$$

where: F_p — factor for combined membrane and bending response, calculated as follows:

$F_p = 1.5$ in general;

$F_p = 1.9 \frac{\sigma}{\sigma_a}$ for $\frac{\sigma}{\sigma_a} \geq 0.8$ for the attached plate flange of primary supporting members;

s — stiffener spacing, in mm;

p — pressure p_H and p_L, calculated according to 2.20.2.2 of this Section, in kN/m^2;

σ — maximum normal stress of hatch cover top plating, in N/mm^2, determined according to Figure 2.20.2.3;

σ_a——permissible stress, see Table 2.20.2.5,, in N/mm^2;

R_{eH} — yield stress of materials, in N/mm^2.

For flange plates under compression, the buckling strength requirements of 2.20.2.6 of this Section are to be complied with.

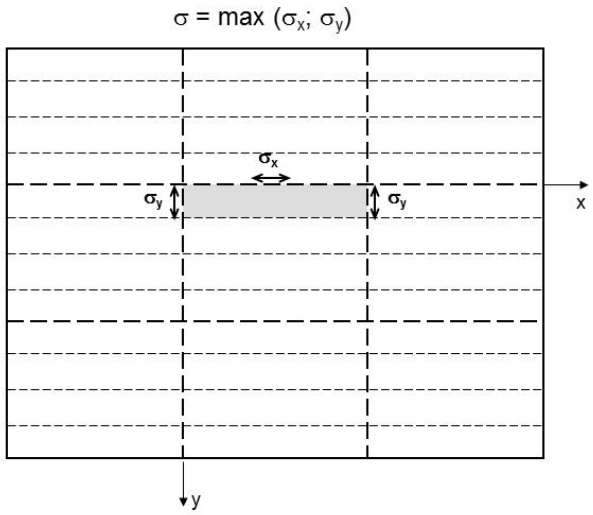

Figure 2.20.2.3

① The local net plate thickness of hatch covers for wheel loading is also to meet the relevant requirements of Section 21 of this Chapter.

② The local net plate thickness of lower plating of double skin hatch covers and box girders are to comply with the following requirements:

The thickness to fulfill the strength requirements is to be obtained from the calculation according to 2.20.2.4 under consideration of allowable stresses according to 2.20.2.5 of this Section. When the lower plating is taken into account as a strength member of the hatch cover, the net thickness, in mm, of lower plating is to be taken not less than 5 mm. When project cargo is intended to be carried on a hatch cover, the net thickness is not to be less than:

$$t = 6.5s \times 10^{-3} \quad \text{mm}$$

where: s— stiffener spacing, in mm.

When the lower plating is not considered as a strength member of the hatch cover, the thickness of the lower plating is not to be less than 5 mm.

Note:

Project cargo means especially large or bulky cargo lashed to the hatch cover. Examples are parts of cranes or wind power stations, turbines, etc. Cargoes that may be considered as uniformly distributed over the hatch cover, e.g. timber, pipes or steel coils need not to be considered as project cargo.

(2) The stiffeners of hatch covers are to comply with the following requirements:

The net section modulus Z and net shear area A_{shr} of uniformly loaded hatch cover stiffeners constrained at both ends are not to be less than:

$$Z = \frac{psl^2}{f_{bc}\sigma_a} \quad \text{cm}^3$$

$$A_{shr} = \frac{8.7\,psl}{\sigma_a}10^{-3} \quad \text{cm}^2$$

where: l — secondary stiffener span, in m, to be taken as the spacing of primary supporting members or the distance between a primary supporting member and the edge support, as applicable. When brackets are fitted at both ends of all stiffener spans, the secondary stiffener span may be reduced by an amount equal to 2/3 of the minimum brackets arm length, but not greater than 10% of the unsupported span, for each bracket;

s — spacing of stiffeners, in mm;

p — p_H and p_L, to be calculated according to 2.20.2.2 of this Section, in kN/m^2;

f_{bc} — boundary coefficient of stiffener, taken equal to:

f_{bc} = 8, in the case of stiffener simply supported at both ends or simply supported at one end and clamped at the other end;

f_{bc} = 12, in the case of stiffener clamped at both ends.

σ_a — allowable stress as defined in Tab.2.20.2.5, in N/mm^2.

For secondary stiffeners of lower plating of double skin hatch covers, requirements mentioned above are not applied due to the absence of lateral loads. For double skin hatch covers of holds designed for ballast or liquid cargo, the stiffeners on lower plating are to be strengthened according to CCS requirements.

The net thickness, in mm, of the stiffener (except U-beams/trapeze stiffeners) web is not to be less than 4 mm.

The net section modulus of secondary stiffeners is to be determined based on an attached plate width assumed equal to the stiffener spacing.

Stiffeners parallel to primary supporting members are to be continuous at crossing primary supporting members, and may be considered for calculations regarding cross-sectional properties of primary members. It is to be verified that the combined stress of those stiffeners induced by the bending of primary supporting members and lateral pressures does not exceed the allowable stresses according to 2.20.2.5 of this Section. When the lower plating is not taken into account as a strength member of the hatch cover, the requirements of this paragraph are not necessary for the stiffeners of lower plating.

For hatch cover stiffeners under compression, sufficient safety against lateral and torsional buckling according to 2.20.2.6 of this Section is to be verified.

For hatch covers subject to wheel loading, the relevant requirements of Section 21 of this Chapter are to be complied with. For hatch covers subject to point loads, stiffener scantlings are to be determined by direct calculations under consideration of the allowable stresses as required in 2.20.2.5 of this Section.

(3) The net scantlings of primary supporting members are to comply with the following requirements:

① Scantlings of primary supporting members are to be obtained from direct calculations according to 2.20.2.4 under consideration of allowable stresses according to 2.20.2.5 of this Section.

For all components of primary supporting members sufficient safety against buckling is to be verified according to 2.20.2.6 of this Section. For biaxially compressed flange plates, the buckling strength is to be verified within the effective width according to 2.20.2.6(3)② of this Section.

The net thickness, in mm, of webs of primary supporting members is not to be less than:

$$t = 6.5s \times 10^{-3} \quad \text{mm}$$

$$t = 5 \quad \text{mm}$$

where: s— spacing of stiffeners, in mm.

② The net scantlings of edge girders are to comply with the following requirements:

Scantlings of edge girders are to be verified according to 2.20.2.4 under consideration of allowable stresses according to 2.20.2.5 of this Section.

The net thickness of the outer edge girders exposed to wash of seawater is not to be less than the largest of the following values:

$$t = 0.0158s\sqrt{\frac{p_A}{0.95R_{eH}}} \quad \text{mm}$$

$$t = 8.5s \times 10^{-3} \quad \text{mm}$$

$$t = 6 \quad \text{mm}$$

where: s — spacing of stiffeners, in mm;

P_A — horizontal weather design pressure, calculated according to 2.20.2.2 of this Section, in kN/m^2;

For the required moment of inertia of edge girders, refer to 2.20.2.9(1)④.

2.20.2.4 Strength calculation

The stresses in hatch covers are to be determined by FE analysis.

The stress calculation model in this section is to be used for both yielding and buckling strength assessments in accordance with 2.20.2.5 and 2.20.2.6, respectively.

The net scantlings as defined in 2.20.2.1(5) are to be used.

(1) General requirements for FEM calculations

For strength calculations of hatch covers by means of finite elements, the cover geometry is to be idealized as realistically as possible. In no case element width is to be larger than stiffener spacing. In way of force transfer points and cutouts the mesh has to be refined where applicable. The ratio of element length to width is not to exceed 3.

The element height of webs of primary supporting members is not to exceed one-third of the web height. Stiffeners, which support plates subjected to lateral pressure loads, are to be included in the FE model idealization. Stiffeners may be modelled by using beam elements, or shell/plate elements. Buckling stiffeners may be disregarded for the stress calculation.

Hatch covers fitted with U-type stiffeners as shown in Figure 2.20.2.4(1) are to be assessed by means of FE analysis.The geometry of the U-type stiffeners is to be accurately modelled using shell/plate elements. Nodal points are to be properly placed on the intersections between the webs

of a U-type stiffener and the hatch cover plate, and between the webs and flange of the U-type stiffener.

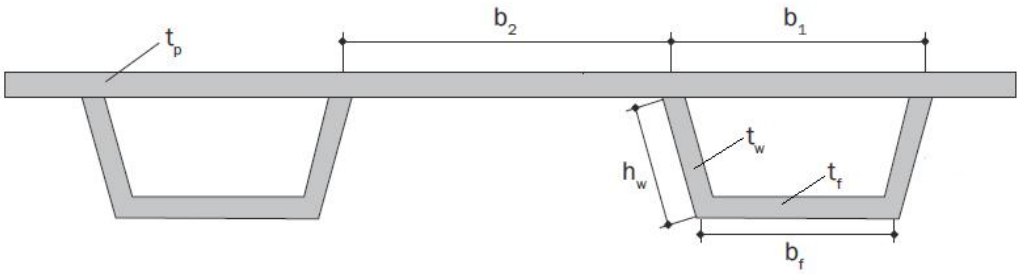

Figure. 2.20.2.4(1) Example of hatch cover fitted with U-type stiffeners

① A right-handed coordinate system is to be used with:
the *x*-axis measured in the longitudinal direction, positive forward;
the *y*-axis measured in the transverse direction, positive to port from the centerline;
the *z*-axis measured in the vertical direction, position upward.

② The FEM is to be performed with net scantlings.

③ The finite element model is to be limited as follows:

(a) for symmetry of the hatch cover girders, loads and supporting boundary conditions about only the x-axis or y-axis, it may be limited to a half of the hatch cover for check;

(b) for non-symmetry of hatch cover girders, loads or supporting boundary conditions about any of the axes, the whole hatch cover may be taken for strength evaluation, see Figure 2.20.2.4(2).

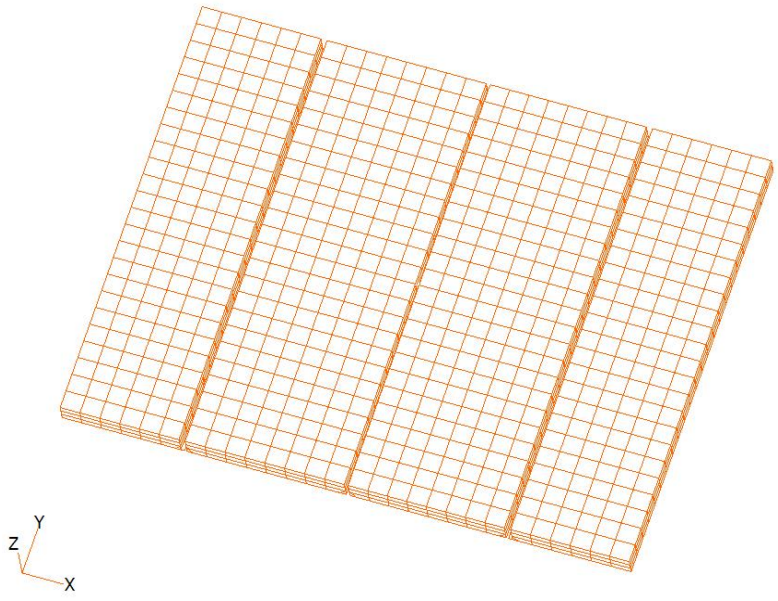

Figure 2.20.2.4(2) Finite Element Hatch Cover Model

④ The model element is to comply with the following requirements:

(a) all plating, including girders and stiffeners, is to be represented by the finite element model;

(b) all plating, such as top plates, bottom plates, brackets, and girder webs, face plates of primary supporting members is to modeled using plate elements, triangular elements are to be avoided where possible;

(c) all stiffeners are to be modeled using beam, rod or plate elements.

⑤ The element mesh size is to be controlled as follows:

(a) the mesh size is not to be greater than the spacing of stiffeners;

(b) the girders are to be represented by at least 3 elements in the depth;

(c) triangular and distorted quadrilateral elements with corner angles less than 60 degrees and greater than 120 degrees are to be avoided.

⑥ Boundary conditions are to be determined as follows:

(a) for symmetry of the hatch cover girders and loads about the xz-plane, the longitudinal displacement of nodes in the symmetric plane and the rotations about the *y* and *z* axes are to be taken as 0 respectively, i.e. $\delta_x = \theta_y = \theta_z = 0$, as shown in Figure 2.20.2.4(3);

(b) for symmetry of the hatch cover girders and loads about the yz-plane, the transverse displacement of nodes in the symmetric plane and rotation about the *x* and *z* axes are to be taken as 0 respectively i.e. $\delta_y = \theta_x = \theta_z = 0$, as shown in Figure 2.20.2.4(3);

(c) boundary nodes in way of bearing pads on the hatch coamings are generally to be fixed against displacement in the *z* direction, i.e. $\delta_z = 0$;

(d) lifting stoppers are to be fixed against displacements in the direction determined by the stoppers;

(e) hinges in folding type hatch covers are to be represented as rigid links which tie together displacements in the *z* direction.

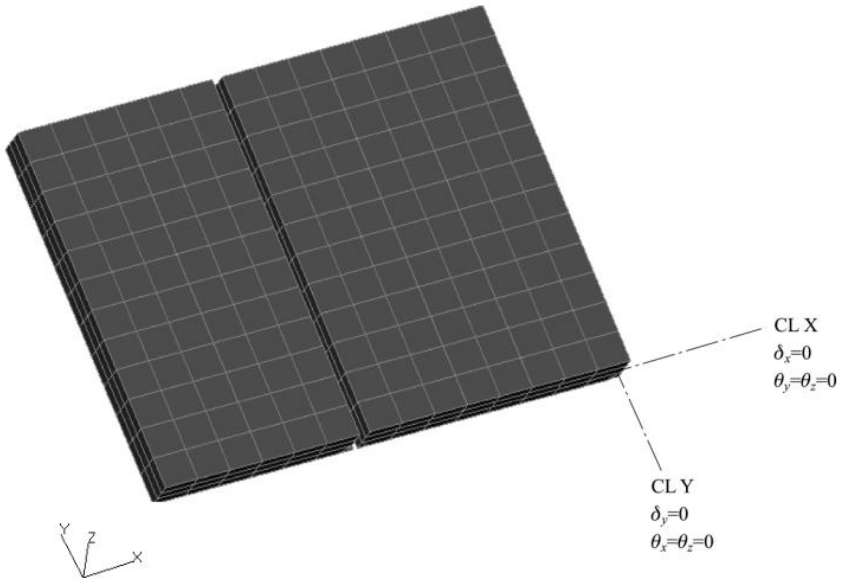

Figure 2.20.2.4(3) Boundary Conditions of Hatch Cover Model

2.20.2.5 Yield strength and deflection criteria of hatch cover structures

(1) Allowable stresses

All hatch cover structures are to comply with the following formulae:

$\sigma_{vm} \leq \sigma_a$, for shell element;

$\sigma_{axial} \leq \sigma_a$, for rod or beam elements.

where: σ_a ——allowable stress in Table 2.20.2.5;

R_{eH} ——yield stress of the material;

σ_{vm} —— the equivalent stress may be taken as follows:

$$\sigma_V = \sqrt{\sigma_x^{\,2} - \sigma_x \cdot \sigma_y + \sigma_y^{\,2} + 3\tau^2} \qquad \text{N/mm}^2$$

where: σ_x — normal stress, in N/mm^2, in x-direction;

σ_y — normal stress, in N/mm^2, in y-direction;

τ — shear stress, in N/mm^2, in the x-y plane;

σ_{axial} —axial stress in rod or beam elements, in N/mm^2.

In case of FEM calculations using shell elements, the stresses are to be read from the centre of the individual element. It is to be observed that, in particular, at flanges of unsymmetrical girders, the evaluation of stress from element centre may lead to non-conservative results. Thus, a sufficiently fine mesh is to be applied in these cases or, the stress at the element edges is not to exceed the allowable stress. Where shell elements are used, the stresses are to be evaluated at the mid plane of the element.

For steels with a yield stress of 390 N/mm^2, it is taken as 368 N/mm^2 for calculation.

Stress concentrations are to be evaluated according to the actual conditions.

Allowable stress Table 2.20.2.5

Members of	Subject to	σ_a , in N/mm^2
Hatch cover structure	External pressure, as defined in 2.20.2.2(1)	$0.80R_{eH}$
	Other loads, as defined in 2.20.2.2(2)~(5)	$0.90R_{eH}$ for static+dynamic load case $0.72R_{eH}$ for static load case

(2) Deflection

The vertical deflection of primary supporting members due to the load stipulated in 2.20.2.2 of this Section is to be not more than 0.0056 l_g, where l_g is the greatest span of primary supporting member.

Note: Where containers are arranged on hatch covers and mixed stowage is allowed, i.e., a 40'-container stowed on top of two 20'-containers, particular attention is to be paid to the deflections of hatch covers. Further the possible contact of deflected hatch covers with cargo in hold has to be considered.

2.20.2.6 Buckling strength of hatch cover structures

(1) General

Buckling strength of all hatch cover structures is to be checked. Buckling assessments are to be performed in compliance with the requirements in Appendix 5.

The net scantlings as defined in 2.20.2.1(5) are to be used for buckling check.

(2) Slenderness requirements

The slenderness requirements are to be in accordance with those specified in Sec 2 of Appendix 5.

The slenderness requirements need not be applied to the lower boundary of double skin hatch covers unless the cargo hold is designed for carriage of ballast or liquid cargo.

The breadth of the primary supporting member flange is to be not less than 40% of their depth for laterally unsupported spans greater than 3.0 m. Tripping brackets attached to the flange may be considered as a lateral support for primary supporting members.

(3) Buckling requirements

① These requirements apply to the buckling assessment of hatch cover structures subjected to compressive and shear stresses and lateral pressures. The buckling assessment is to be performed for the following structural elements:

- Stiffened and unstiffened panels, including curved panels and panels stiffened with U-type stiffeners.
- Web panels of primary supporting members in way of opening.

The buckling strength assessment of coaming parts is to be done according to this paragraph.

For rule application, the panel types and assessment methods, the applied lateral pressure and stresses, safety factors and buckling check criteria are defined in 2.20.2.6(3)②-2.20.2.6(3)⑤, respectively. The procedure and detailed requirements for buckling assessment are given in Section 4 of Appendix 5, including idealization of irregular plate panels, definition of reference stresses and buckling criteria.

Unless otherwise specified, the symbols used in 2.20.2.6(3) are defined in Appendix 5.

② Panel types and assessment methods

The plate panel of a hatch cover structure is to be modelled as stiffened panel (SP) or unstiffened panel (UP) as defined in 4.2, Section 4 of Appendix 5. Assessment Method A (-A) and Method B (-B) as defined in 1.3, Section 1 of Appendix 5 are to be used in accordance with Table 2.20.2.6(3)①, Figure 2.20.2.6(3)① and Figure 2.20.2.6(3)②. For a web panel with opening, the procedure for opening should be used for its buckling assessment.

For a hatch cover fitted with U-type stiffeners, the additional buckling assessment requirements specific for panels with U-type stiffeners in 5.2.5, Section 5 of Appendix 5 are also to be followed.

Structural members and assessment methods **Table 2.20.2.6(3)①**

Structural elements	**Assessment method**[(1)(2)]	**Normal panel definition**
Hatch cover top/bottom plating structures, see Figure 2.20.2.6(3)①		

Hatch cover top/bottom plating	SP-A	Length: between transverse girders Width: between longitudinal girders
Irregularly stiffened panels	UP-B	Plate between local stiffeners/PSM
Hatch cover web panels of primary supporting members, see Figure 2.20.2.6(3)②		
Web of transverse/longitudinal girder (single skin type)	UP-B	Plate between local stiffeners/face plate/PSM
Web of transverse/longitudinal girder (double skin type)	SP-B(3)	Length: between PSM Width: full web depth
Web panel with opening	Procedure for opening	Plate between local stiffeners/face plate/PSM
Irregularly stiffened panels	UP-B	Plate between local stiffeners/face plate/PSM
Note 1: SP and UP stand for stiffened and unstiffened panel respectively. Note 2: A and B stand for Method A and Method B respectively. Note 3: In case that the buckling carlings/brackets are irregularly arranged in the web of transverse/longitudinal girder, UP-B method may be used.		

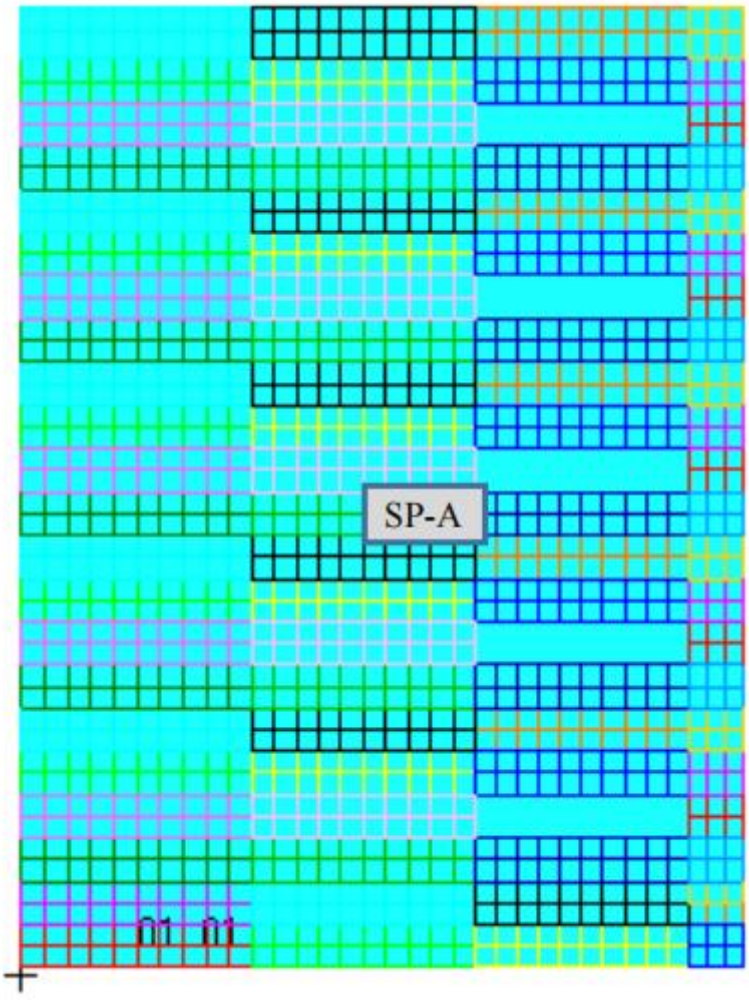

Figure 2.20.2.6(3)①

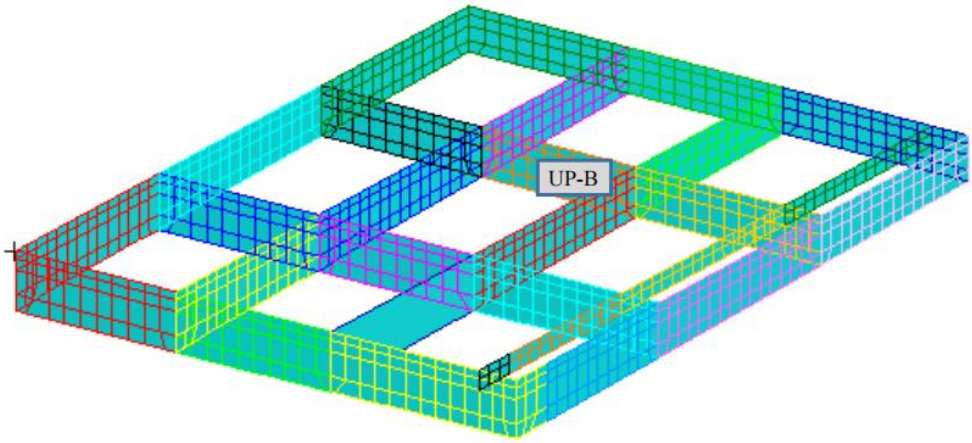

Figure 2.20.2.6(3)②

③ Applied lateral pressure and stresses

The buckling assessment of hatch covers is based on the lateral pressure as defined in 2.1 and 2.2, and stresses obtained from FE analysis, refer to 2.20.2.4.

④ Safety factors

For all hatch cover structural members, safety factor S=1.0 is to be applied to both of the plating and stiffener buckling capacity formulas as defined in 5.2.2, Section 5 of Appendix 5 and 5.2.3, Section 5 of Appendix 5, respectively.

⑤ Buckling acceptance criteria

A structural member is considered to have an acceptable buckling strength if it satisfies the following criterion:

$$\eta_{act} \leq \eta_{all}$$

where: η_{act} —— Buckling utilisation factor based on the applied stress, as defined in 1.3.2.2, Section 1 of Appendix 5 and Section 4 of Appendix 5, and calculated per Section 5 of Appendix 5.

η_{all} —— Allowable buckling utilisation factor, taken as given in Tab.2.20.2.6(3)⑤.

Allowable buckling utilisation factors **Table 2.20.2.6(3)⑤**

Structural component	Subject to	η_{all}, allowable buckling utilisation factor
Plates and stiffeners Web of PSM	External pressure, as defined in 2.20.2.2(1)	0.80
	Other loads, as defined in 2.20.2.2(2)~(5)	0.90 for static+dynamic load case 0.72 for static load case

2.20.2.7 Details of hatch covers

(1) Container foundation on hatch covers

Container foundations on hatch covers are to be in compliance with the relevant requirements of Appendix 1 of Chapter 7 of this PART. The calculated stresses of substructures of container

foundations under cargo and container loads according to 2.20.2.2 of this Section are to comply with the requirements of 2.20.2.5 of this Section.

(2) Weathertightness

In addition to the following requirements, the hatch covers are also to meet the relevant requirements of IACS REC14.

① Packing material (general)

The packing material is to be suitable for all expected service conditions of the ship and is to be compatible with the cargoes to be transported. The packing material is to be selected with regard to dimensions and elasticity in such a way that expected deformations may be carried. Forces are to be carried by the steel structure only.

The packings are to be compressed so as to give the necessary tightness effect for all expected operating conditions. Special consideration is to be given to the packing arrangement in ships with large relative movements between hatch covers and coamings or between hatch cover sections.

② Dispensation of weathertight gaskets

For hatch covers of cargo holds intended solely for the transport of containers, upon request by the Owner and subject to compliance with the following conditions, the fitting of weathertight gaskets according to 2.20.2.7(2) may be dispensed with:

- The hatchway coamings are to be not less than 600 mm in height.
- For weather deck hatch covers located above a depth $H(x)$, $H(x)$ is to comply with the following criterion:

$$H(x) \geq T_{fb} + f_b + h \qquad \text{m}$$

where: T_{fb} — draught, in m, corresponding to the assigned summer load line;

f_b — minimum required freeboard, in m, determined in accordance with ICLL Regulation 28 as modified by further regulations as applicable;

h = 4.6 m for $\frac{x}{L_L} \leq 0.75$;

h = 6.9 m for $\frac{x}{L_L} > 0.75$.

- Labyrinths, gutter bars or equivalents are to be fitted proximate to the edges of each panel in way of the coamings. The clear profile of these openings is to be kept as small as possible.
- Where a hatch is covered by several hatch cover panels, the clear opening of the gap in between the panels is to be not wider than 50 mm.
- The labyrinths and gaps between hatch cover panels are to be considered as unprotected openings with respect to the requirements of intact and damage stability calculations.
- With regard to drainage of cargo holds and the necessary fire-fighting system, refer to the relevant requirements of Chapter 6, PART EIGHT of the Rules.
- Bilge alarms are to be provided in each hold fitted with non-weathertight covers.
- Furthermore, Chapter 3 of IMO MSC/Circ.1087 is to be complied with for the storage and segregation of containers carrying dangerous goods.

③ Cross-joint of multi-panel covers are to be provided with efficient drainage arrangements.

2.20.2.8 Hatch coamings are to comply with the following requirements:

(1) The net thickness of weather deck hatch coamings is not to be less than the larger of the following values:

- For Type-1 ships:

$$t = 0.0142s\sqrt{\frac{p_A}{0.95R_{eH}}} \quad \text{mm}$$

$$t = 6 + \frac{L_1}{100} \quad \text{mm}$$

- For Type-2 ships:

$$t = 0.016s\sqrt{\frac{p_{coam}}{0.95R_{eH}}} \quad \text{mm}$$

$$t_{\min} = 9.5 \quad \text{mm}$$

where: s — stiffener spacing, in mm;

P_A — horizontal weather design load, in kN/m^2, to be calculated according to 2.20.2.2(2) ① of this Section;

p_{coam} ——horizontal weather design load, in kN/m^2, to be calculated according to 2.20.2.2(2) ② of this Section;

$L_1 = L$, but need not be taken as greater than 300 m.

The continuous longitudinal hatch coamings within 0.4L amidships are also to comply with the relevant requirements of Section 2 of this Chapter.

(2) The stiffeners of hatch coaming are to meet the following requirements:

The stiffeners are to be continuous at the coaming stays.

For stiffeners with both ends constrained, the net section modulus Z and net shear area A_{shr}, , calculated on the basis of net thickness, are not to be less than:

- For Type-1 ships:

$$Z = \frac{p_A s l^2}{f_{bc} R_{eH}} \quad \text{cm}^3$$

$$A_{shr} = \frac{p_A s l^2}{R_{eH}} 10^{-2} \quad \text{cm}^2$$

where: f_{bc} =12 in general

= 8 for the end spans of stiffeners sniped at the coaming corners;

l — stiffener span, in m, to be taken as the spacing of coaming stays;

s — stiffener spacing, in mm;

P_A — horizontal weather design load, in kN/m^2, to be calculated according to 2.20.2.2(2) ① of this Section.

For sniped stiffeners of coaming at hatch corners, section modulus and shear area at the fixed support have to be increased by 35%. The gross thickness of the coaming plate at the sniped stiffener end is not to be less than:

$$t_{gr} = 19.6\sqrt{\frac{p_A s(l - 0.0005s)}{1000 R_{eH}}} \quad \text{mm}$$

- For Type-2 ships:

$$Z = 1.21\frac{p_{coam} s l^2}{f_{bc} c_p R_{eH}} \quad \text{cm}^3$$

where: f_{bc} —16 in general
12 for the end spans of stiffeners sniped at the coaming corners;
l —stiffener span, in m, to be taken as the spacing of coaming stays;
s — stiffener spacing, in mm;
P_A — horizontal weather design load, in kN/m^2, to be calculated according to 2.20.2.2(2)① of this Section;
p_{coam} — horizontal weather design load, in kN/m^2, to be calculated according to 2.20.2.2(2)② of this Section;
c_p — ratio of the plastic section modulus to the elastic section modulus of the stiffeners with an attached plate breadth, in mm, equal to 40t, where t is the plate net thickness
c_p — 1.16 in the absence of more precise evaluation

The horizontal stiffeners of continuous longitudinal hatch coamings within 0.4L amidships are also to comply with the relevant requirements of Section 2 of this Chapter.

(3) Coaming stays are to be designed for the loads transmitted through them and are to comply with the following requirements, in addition to the allowable stresses stipulated in 2.20.2.5 of this Section.

① Coaming stay section modulus and web thickness

At the connection with deck, the net section modulus Z, in cm^3, and the gross thickness t_w, in mm, of the coaming stays designed as beams with flange (examples 1 and 2 are shown in Figure 2.20.2.8(3)) are to be taken not less than:

$$Z = \frac{P s_c H_c^2}{1.9 R_{eH}} \quad \text{cm}^3$$

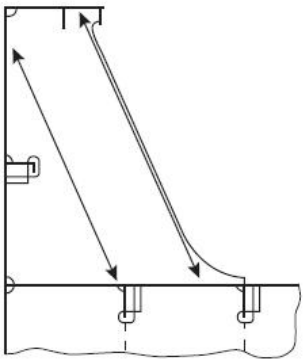
$$t_w = \frac{2 P s_c H_c}{h R_{eH}} \quad \text{mm}$$

where: H_C — stay height, in m;
s_c — stay spacing, in mm;
h — stay depth, in mm, at the connection with the deck;
p — pressure on coaming, in kN/m^2 , taken as p_A defined in 2.20.2.2(2)① in general and as p_{coam} defined in 2.20.2.2(2)② for Type-2 ships.

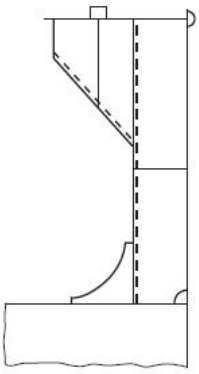
For other designs of coaming stays, such as those shown in Figure 2.20.2.8(3), examples 3 and 4, the stresses are to be determined through a grillage analysis or FEM. The calculated stresses are to comply with the permissible stresses according to 2.20.2.5 of this Section.

Coaming stays are to be supported by appropriate substructures. Face plates may only be included in the calculation of section modulus of coaming stays if an appropriate substructure is provided and welding provides an adequate joint.

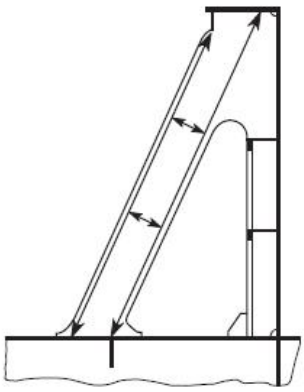
Webs are to be connected to the deck by fillet welds on both sides with a throat thickness of not less than $0.44t_w$. For Type-2 ships, toes of stay webs are to be connected to the deck plating with full or partial penetration double bevel welds extending over a distance not less than 15% of the stay width. For other ship types the size of welding for toes of webs at the lower end of coaming stays is to comply with the relevant requirements of Chapter 1 of this PART.



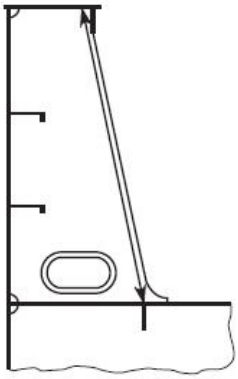
Example 1



Example 2



Example 3



Example 4

Figure 2.20.2.8(3) Examples of coaming stays

② For coaming stays, which transfer friction forces at hatch cover supports, fatigue strength is to be considered.

(4) The hatch coaming is also to comply with the following requirements:

① Hatch coamings which are part of the longitudinal hull structure are to be designed according to the relevant requirements of Section 2 of this Chapter.

② For structural members welded to coamings and for cutouts in the top of coamings, sufficient fatigue strength is to be verified.

③ Longitudinal hatch coamings with a length exceeding 0.1L are to be provided with tapered brackets or equivalent transitions and a corresponding substructure at both ends. At the end of the brackets, they are to be connected to the deck by full penetration welds of minimum 300 mm in length.

④ The local details are to be designed to transfer the loads on the hatch covers to the hatch coamings, and, through them, to the deck structures below. Hatch coamings and supporting structures are to be adequately stiffened to accommodate the loading from hatch covers, in longitudinal, transverse and vertical directions. Structures under deck are to be checked against the load transmitted by the stays. Unless otherwise stated, welding and material are to comply with the relevant requirements of CCS.

⑤ On ships carrying cargo on deck, such as timber, coal or coke, the stays are to be spaced not more than 1.5 m apart.

⑥ Coaming plates are to extend to the lower edge of the deck beams or hatch side girders are to be fitted that extend to the lower edge of the deck beams. Extended coaming plates and hatch side girders are to be flanged or fitted with face bars or half-round bars. See Figure 2.20.2.8(4).

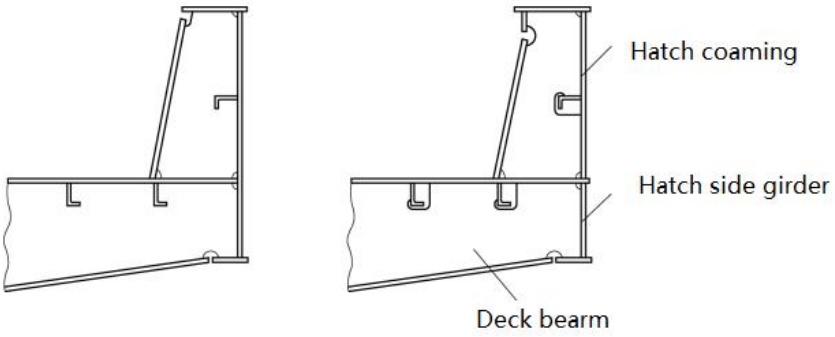


Figure 2.20.2.8(4) Example for the Extension of Coaming Plates

⑦ Drainage arrangement at the coaming is to comply with the following requirements:

If drain channels are provided inside the line of gasket by means of a gutter bar or vertical extension of the hatch side and end coaming, drain openings are to be provided at appropriate positions of the drain channels.

Drain openings in hatch coamings are to be arranged with sufficient distance to areas of stress concentration (e.g. hatch covers, transitions to crane posts).

Drain openings are to be arranged at the ends of drain channels and are to be provided with non-return valves to prevent ingress of water from outside. It is unacceptable to connect fire hoses to the drain openings for this purpose.

If a continuous outer steel contact between cover and ship structure is arranged, drainage from the space between the steel contact and the gasket is also to be provided.

2.20.2.9 Closing arrangements of weathertight steel hatch covers

(1) Securing arrangements

① General requirements

Securing devices between cover and coaming and at cross-joints are to be installed to provide weathertightness. Sufficient packing line pressure is to be maintained. Securing

devices are to be appropriate to bridge displacements between cover and coaming due to hull deformations.

Securing devices are to be of reliable construction and effectively attached to the hatchway coamings, decks or covers. Individual securing devices on each cover are to have approximately the same stiffness characteristics. According to the requirements of 2.20.2.3(3)② of this Section, a sufficient number of securing devices is to be provided at each side of the hatch cover, including that consisting of several parts.

The materials of stoppers, securing devices and their welding are to comply with the relevant requirements of CCS Rules for Materials and Welding. Specifications of the materials are to be shown in the drawings of the hatch covers.

② Rod cleats

Where rod cleats are fitted, resilient washers or cushions are to be incorporated.

③ Hydraulic cleats

Where hydraulic cleating is adopted, a positive means is to be provided so that it remains mechanically locked in the closed position in the event of failure of the hydraulic system.

④ Cross-sectional area of the securing devices

The gross cross-sectional area of the securing devices is not to be less than:

$$A = 0.28qS_{SD}k_l \qquad \text{cm}^2$$

where: q —packing line pressure, in N/mm, minimum 5 N/mm;

S_{SD} — spacing between securing devices, in m, not to be taken less than 2 m;

$k_l = (\frac{235}{R_{eH}})^e$;

R_{eH} — the minimum yield stress of material, in N/mm^2, but not to be taken greater than $0.7R_m$;

R_m — tensile strength of material, in N/mm^2;

e =0.75 for $R_{eH} > 235$ N/mm^2;

e =1.00 for $R_{eH} \le 235$ N/mm^2.

Rods or bolts are to have a gross diameter not less than 19 mm for hatchways exceeding 5m^2 in area.

Securing devices of special design in which significant bending or shear stresses occur may be designed as anti-lifting devices according to 2.20.2.9(1)⑤. The design load is taken as the packing line pressure q multiplied by the spacing S_{SD} between securing devices.

⑤ Anti-lifting devices

The securing devices of hatch covers, on which cargo is to be lashed, are to be designed for the lifting forces resulting from loads according to 2.20.2.2(4) of this Section, refer to Figure 2.20.2.9(1). Unsymmetrical loadings, which may occur in practice, are to be considered. Under these loadings the equivalent stress in the securing devices is not to exceed:

$$\sigma_V = \frac{150}{k_l} \qquad \text{N/mm}^2$$

where: k_l — as in 2.20.2.9(1)④.

Note: The partial load cases given in Table 2.20.2.2(4) may not cover all unsymmetrical loadings, critical for hatch cover lifting.

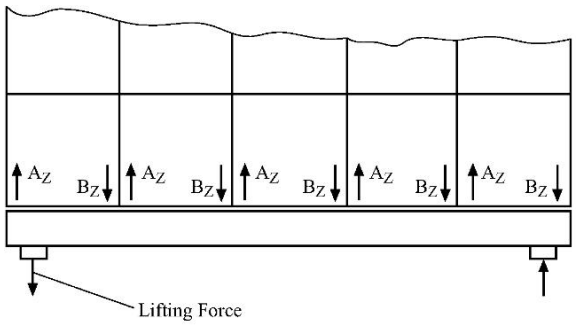

Figure 2.20.2.9(1) Lifting Forces at a Hatch Cover

The anti-lifting devices may be dispensed with according to the following requirements:
In the absence of hatch cover lifting under loads arising from the ship's rolling motion, securing devices for hatch covers may be omitted. In such cases, it is to be proven by means of grillage or finite element analysis that an equilibrium condition is achieved using compression only boundary elements for the vertical hatch cover supports. If securing devices are omitted, transverse cover guides are to be effective up to a height h_E, as shown in Figure 2.20.2.9(2), where h_E is not to be less than:

$$h_E = 1.75(2se + d^2)^{0.5} - 0.75d \quad \text{mm}$$

$$h_{E\min} = \text{height of the cover edge plate} + 150 \quad \text{mm}$$

where: e — largest distance from the inner edge of the transverse cover guide to the end of the cover edge plate, in mm;

s — total clearance within the transverse cover guide, with $10 \le s \le 40$, in mm;

d — distance between upper edge of transverse stopper and hatch cover support, in mm.

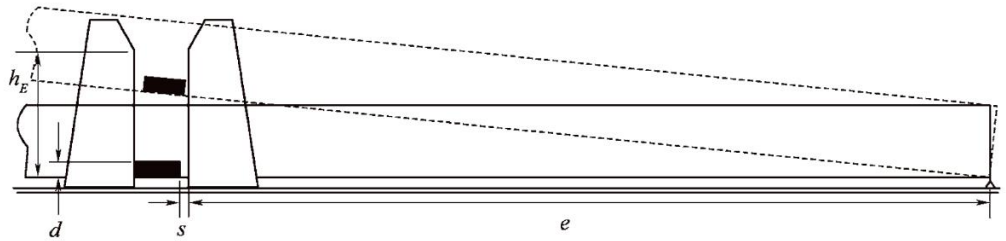

Figure 2.20.2.9(2) Height of Transverse Cover Guide

The transverse cover guides and their substructure are to be dimensioned in accordance with the transverse loads acting at a height h_E.

(2) Hatch cover supports, stoppers and supporting structures

① Horizontal mass forces

For the design of hatch cover supports, the horizontal mass force is to be taken as follows:

$$F_h = ma$$

where: F_h— horizontal mass force, in kN;

$a_X = 0.2g$ in longitudinal direction;

$a_Y = 0.5g$ in transverse direction;

m— sum of mass of cargo lashed on the hatch cover and mass of hatch cover.

The accelerations in longitudinal direction and in transverse direction need not be considered as acting simultaneously.

② Hatch cover supports

For the transmission of the support forces resulting from the load cases specified in 2.20.2.2 of this Section and of the horizontal mass forces specified in (2)①, supports are to be provided which are to be designed such that the nominal surface pressures in general do not exceed the values obtained from the following formula:

$$p_{n\max} = dp_n \qquad \text{N/mm}^2$$

where: d = 3.75-0.015L;

$d_{\max} = 3.0$;

$d_{\min} = 1.0$, in general;

$d_{\min} = 2.0$, for partial loading conditions, see 2.20.2.2(5);

P_n — Allowable nominal surface pressure, see Table 2.20.2.9(2).

Allowable Nominal Surface Pressure P_n Table 2.20.2.9(2)

Support material	P_n (N/mm^2) when loaded by	
	Vertical force	Horizontal force (on stoppers)
Hull structural steel	25	40
Hardened steel	35	50
Lower friction materials	50	—

For metallic supporting surfaces not subjected to relative displacements, the following nominal surface pressure applies:

$$p_{n\max} = 3p_n \qquad \text{N/mm}^2$$

Note: When the maker of vertical hatch cover support material can provide proof that the material is sufficient for the increased surface pressure, not only statically but under dynamic conditions including relative motion for adequate number of cycles, permissible nominal surface pressure may be relaxed at the discretion of CCS. However, realistic long term distribution of spectra for vertical loads and relative horizontal motion is to be assumed and agreed with CCS.

Drawings of the supports are to be submitted for approval. In the drawings of supports, the permitted maximum pressure given by the material manufacturer is to be indicated.

Where large relative displacements of the supporting surfaces are to be expected, the use of material having low friction properties is recommended.

The substructures of the supports are to be of such a design that a uniform pressure distribution is achieved.

Irrespective of the arrangement of stoppers, the supports are to be able to transmit the following force P_h in the longitudinal and transverse direction:

$$P_h = \mu \cdot \frac{P_V}{\sqrt{d}}$$

where: P_V — vertical supporting force;

μ — frictional coefficient;

μ = 0.5 steel to steel.

For non-metallic, low-friction support materials on steel, the friction coefficient μ may be reduced but not to be less than 0.35 and it is to be submitted to CCS for approval.

Supports as well as the adjacent structures and substructures are to be designed such that the allowable stresses in 2.20.2.5 of this Section are not exceeded.

For substructures and adjacent structures of supports subjected to horizontal forces P_h, a fatigue strength is to be considered.

③ Hatch cover stoppers

Hatch covers are to be sufficiently secured against horizontal shifting. Stoppers are to be provided for hatch covers on which cargo is carried.

The greater of the loads resulting from 2.20.2.2(2) of this Section and 2.20.2.9(2)① is to be applied for the dimensioning of the stoppers and their substructures.

The allowable stress in stoppers and their substructures, in the cover, and of the coamings is to be determined according to 2.20.2.5 of this Section and in addition, the requirements in 2.20.2.9(2)② are to be taken into consideration.

Specifically for Type-2 ships, the following additional requirements are to be complied with:

Hatch covers are to be effectively secured, by means of stoppers, against the transverse forces arising from a pressure of 175 kN/m^2.

With the exclusion of No.1 hatch cover, hatch covers are to be effectively secured, by means of stoppers, against the longitudinal forces acting on the forward end arising from a pressure of 175 kN/m^2.

No. 1 hatch cover is to be effectively secured, by means of stoppers, against the longitudinal forces acting on the forward end arising from a pressure of 230 kN/m^2.

This pressure may be reduced to 175 kN/m^2 when a forecastle is fitted in accordance with Section 13, Chapter 8 of this PART.

The equivalent stress in stoppers and their supporting structures, and calculated in the throat of the stopper welds is not to exceed the allowable value of $0.8R_{eH}$.

2.20.2.10 Corrosion addition and steel renewal

(1) Corrosion addition for hatch covers and hatch coamings

For scantlings of hatch cover components, the general corrosion additions t_S, as shown in Table 2.20.2.10, is required.

Corrosion Addition t_S for Hatch Covers and Hatch Coamings Table 2.20.2.10

Application	Structure	t_S[mm]
Weather deck hatches of container ships, car carriers, paper carriers and passenger vessels	Hatch covers	1.0
	Hatch coamings	1.5 for $t \le 10$
		$\frac{0.1t}{\sqrt{K}}+0.5$, but not greater than 3, for $t>10$
Weather deck cargo hatches of Type-2 ships	Hatch covers in general	2.0
	Top and bottom plating of double skin hatch covers	2.0
	Internal structure of double skin hatch covers	1.5
	Hatch coamings and coaming stays	1.5
Weather deck hatches of all other ships	Hatch covers in general	2.0
	Weather exposed plating and bottom plating of double skin hatch covers	1.5
	Internal structure of double skin hatch covers and closed box girders	1.0
	Hatch coamings not part of the longitudinal hull structure	1.5
	Hatch coamings part of the longitudinal hull structure	1.5 for $t \le 10$
		$\frac{0.1t}{\sqrt{K}}+0.5$, but not greater than 3, for $t>10$
	Coaming stays and stiffeners	1.5

Notes:

t: net thickness of hatch coaming required by the Rules.

K: material factor.

(2) Steel renewal

Steel renewal is required where the gauged thickness is less than t_{net} + 0.5 mm for

- single skin hatch covers,
- the plating of double skin hatch covers, and
- coaming structures the corrosion additions t_S of which are given in Table 2.20.2.10.

Coating is to be maintained in GOOD condition, as defined in 5.1.5.1(15), Chapter 5 of PART ONE of the Rules.

For internal structure of double skin hatch covers, thickness gauging is required when hatch cover top or bottom plating renewal is to be carried out or when it is deemed necessary by CCS surveyor, on the basis of the plating corrosion or deformation. In these cases, steel renewal for the internal structures is to be required where the gauged thickness is less than t_{net}.

For corrosion addition t_S = 1.0 mm, the thickness for steel renewal is t_{net} and coating or annual gauging may be used for substitution of renewal when gauged thickness is between t_{net} and t_{net} + 0.5 mm.

For coaming structures, the corrosion additions t_S of which are not given in Table 2.20.2.10, steel renewal and coating or annual gauging are to be in accordance with the relevant requirements of CCS.

2.20.3 Steel pontoon covers

2.20.3.1 The design load of steel pontoon covers is to comply with the following requirements:

(1) The design load of vertical exposed hatch covers is to be calculated according to Table 2.20.2.2(1) of this Section.

(2) The permissible cargo load p on hatch covers is to be specified by the Owner or designer and included in the loading manual, complying with the following requirements:

① The permissible cargo load p for 'tween deck hatch covers is not to be less than:

$$p = 7.06h \qquad \text{kN/m}^2$$

where: h — the vertical distance, in m, measured from the hatch cover to the underside of hatch cover stiffeners on deck above.

This requirement does not apply to multi-purpose ships of which the 'tween deck hatch covers are used as 'tween deck, see Figure 2.20.3.1(2) of this Section.

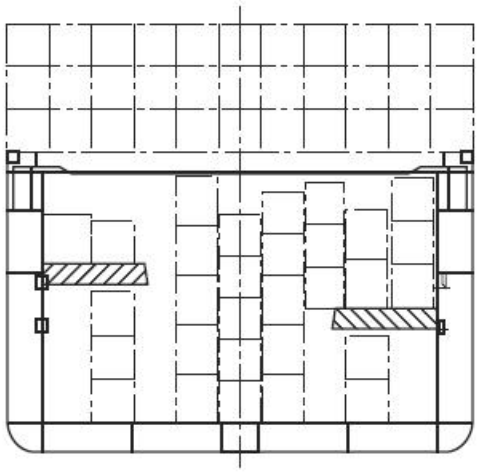

Figure 2.20.3.1(2)

② The permissible cargo load p for hatch covers in the accommodation spaces is not to be less than 12.7 kN/m^2.

2.20.3.2 The local scantlings of hatch covers are to comply with the following requirements:

(1) The thickness t of the top plating of steel hatch covers is not to be less than that obtained from the following formula:

$$t = 0.01s \quad \text{mm,} \quad \text{but in no case to be less than 6 mm.}$$

where: s— spacing of stiffeners, in mm.

(2) The scantlings of stiffeners and girders of steel pontoon covers are to comply with the following requirements:

① Where the uniformly distributed design load of vertical exposed hatch covers is applied, the section modulus W and the section moment of inertia I of stiffeners are not to be less than:

$$W = 7.82Kspl^2 \times 10^{-4} \quad \text{cm}^3$$

$$I = 1.44spl^3 \times 10^{-3} \quad \text{cm}^4$$

where: p— vertical weather design load, in kN/m^2;

s— spacing of stiffeners, in mm;

l— span of stiffener, in m;

K—material factor.

② Where the uniformly distributed cargo load is applied, the section modulus W and the section moment of inertia I of stiffeners are not to be less than:

$$W = 1.064Kspl^2 \times 10^{-3} \quad \text{cm}^3$$

$$I = 1.8spl^3 \times 10^{-3} \quad \text{cm}^4$$

where: p—permissible cargo load, in kN/m^2;

s—spacing of stiffeners, in mm;

l—span of stiffener, in m;

K—material factor.

③ Where the ends of stiffeners are effectively bracketed or continuous, the values of section modulus and moment of inertia may be reduced respectively by 33% and 80% than those obtained from ① or ②.

④ The scantlings of girders of steel pontoon covers are to be determined by direct calculations. Where steel pontoon covers are subject to uniformly distributed loading and girders are fitted in one direction only, however, the scantlings of girders may also be determined according to ① and ②.

2.20.3.3 The direct strength calculation of steel pontoon covers is to be in compliance with the requirements of 2.20.2.4 of this Section.

2.20.3.4 Yield strength and deformation criteria of steel hatch covers of steel pontoon covers

The yield strength and deflection of steel pontoon covers are to meet the requirements of Table 2.20.3.4.

Steel Pontoon Covers **Table 2.20.3.4**

Load	Allowable positive stress $[\sigma]$ (N/mm^2)	Allowable deflection (m)
Vertical weather design load	$0.70R_{eH}$	$0.0049\,l$
Loads other than vertical weather design load	$0.65R_{eH}$	$0.0044\,l$

2.20.3.5 The buckling strength of steel pontoon covers is to meet the requirements of Table 2.20.3.5(1).

Buckling Strength Criteria of Steel Pontoon Covers **Table 2.20.3.5(1)**

Structural member		Criteria
Top panels of hatch	Girders fitted in uni-axial direction	The normal stress of top panels in compression of girders is not to exceed 0.8 times the critical buckling stress σ_c, σ_c may be calculated according to 2.20.3.5(1)

Structural member		Criteria
covers	Girders fitted in bi-axial directions	Biaxial compressive stress of top panels, when calculated by means of finite plate element model, is to be in accordance with the relevant requirements in 2.20.2.6(1) of this Section
Girder webs		The shear stress of girder web panels is not to exceed 0.8 times the critical shear buckling stress τ_c, τ_c may be calculated according 2.20.3.5(3)
Stiffeners parallel to girders		The normal stress of attached plating of stiffeners in compression of girders parallel to stiffeners is not to exceed 0.8 times the critical buckling stress σ_c, σ_c may be calculated according to 2.20.3.5(2)

(1) Hatch cover plating critical stress

The compressive stress σ in the hatch cover plate panels, induced by the bending of primary supporting members parallel to the direction of secondary stiffeners, is not to exceed 0.8 times the critical buckling stress σ_{c1}, to be evaluated as defined below:

$$\sigma_{c1} = \sigma_{E1} \qquad \text{for } \sigma_{E1} \le \frac{R_{eH}}{2}$$

$$\sigma_{c1} = R_{eH}\left(1 - \frac{R_{eH}}{4\sigma_{E1}}\right) \qquad \text{for } \sigma_{E1} > \frac{R_{eH}}{2}$$

where: R_{eH} — yield stress of the material, in N/mm^2;

σ_{E1} = $3.6E\left(\frac{t}{1000s}\right)^2$, in N/mm^2;

E — modulus of elasticity, in N/mm^2, = 2.06×10^5 for steel;

t — net thickness of plate panel, in mm;

s — spacing of secondary stiffeners, in m.

The mean compressive stress σ in each of the hatch cover plate panels, induced by the bending of primary supporting members perpendicular to the direction of secondary stiffeners, is not to exceed 0.8 times the critical buckling stress σ_{c2}, to be evaluated as defined below:

$$\sigma_{c2} = \sigma_{E2} \qquad \text{for } \sigma_{E2} \le \frac{R_{eH}}{2}$$

$$\sigma_{c2} = R_{eH}\left(1 - \frac{R_{eH}}{4\sigma_{E2}}\right) \qquad \text{for } \sigma_{E2} > \frac{R_{eH}}{2}$$

where: R_{eH} — yield stress of the material, in N/mm^2;

σ_{E2} = $0.9mE\left(\frac{t}{1000s_s}\right)^2$, in N/mm^2;

m = $c\left[1 + \left(\frac{s_s}{l_s}\right)^2\right]^2 \frac{2.1}{\psi + 1.1}$

E — modulus of elasticity, in N/mm^2, = 2.06×10^5 for steel;

t — net thickness of plate panel, in mm;

s_s — length of the shorter side of the plate panel, in m;

l_s — length of the longer side of the plate panel, in m;

ψ — ratio between smallest and largest compressive stress;

c = 1.3 when plating is stiffened by primary supporting members;

c = 1.21 when plating is stiffened by secondary stiffeners of angle or T type;

c = 1.1 when plating is stiffened by secondary stiffeners of bulb type;

c = 1.05 when plating is stiffened by flat bar.

The biaxial compressive stress in the hatch cover panels, when calculated by means of FEM shell element model, is to be in accordance with the requirements of 2.20.2.6, Chapter 2 of this PART.

(2) Hatch cover secondary stiffeners critical stress

The compressive stress σ in the top flange of secondary stiffeners, induced by the bending of primary supporting members parallel to the direction of secondary stiffeners, is not to exceed 0.8 times the critical buckling stress σ_{cs}, to be evaluated as defined below:

$$\sigma_{CS} = \sigma_{ES} \qquad \text{for} \quad \sigma_{ES} \le \frac{R_{eH}}{2}$$

$$\sigma_{cs} = R_{eH}\left(1 - \frac{R_{eH}}{4\sigma_{ES}}\right) \qquad \text{for} \quad \sigma_{ES} > \frac{R_{eH}}{2}$$

where: R_{eH} — yield stress of the material, in N/mm^2;

σ_{ES} — ideal elastic buckling stress of the secondary stiffener, in N/mm^2, = minimum between σ_{E3} and σ_{E4};

σ_{E3} = $\dfrac{0.001EI_a}{Al^2}$, in N/mm^2;

E — modulus of elasticity, in N/mm^2, = 2.06×10^5 for steel;

I_a — moment of inertia of the secondary stiffener, in cm^4, including a top flange equal to the spacing of secondary stiffeners;

A — cross-sectional area of the secondary stiffener, in cm^2, including a top flange equal to the spacing of secondary stiffeners;

l — span of the secondary stiffener, in m;

σ_{E4} = $\dfrac{\pi^2 EI_w}{10^4 I_p l^2}\left(m^2 + \dfrac{K}{m^2}\right) + 0.385E\dfrac{I_t}{I_p}$, N/mm^2;

K = $\dfrac{Cl^4}{\pi^4 EI_w} \times 10^6$;

m — number of half waves, given by Table 2.20.3.5(2);

I_w — sectorial moment of inertia of the secondary stiffener about its connection with the plating, in cm^6:

$I_w = \dfrac{h_w^3 t_w^3}{36} \times 10^{-6}$, for flat bar secondary stiffeners;

$I_w = \dfrac{t_f b_f^3 h_w^2}{12} \times 10^{-6}$, for "Tee" secondary stiffeners;

$I_w = \dfrac{b_f^3 h_w^2}{12(b_f + h_w)^2}[t_f(b_f^2 + 2b_f h_w + 4h_w^2) + 3t_w b_f h_w] \times 10^{-6}$, for angles and bulb secondary stiffeners;

I_p — polar moment of inertia of the secondary stiffener about its connection with the plating, in cm^4:

$I_p = \dfrac{h_w^3 t_w}{3} \times 10^{-4}$, for flat bar secondary stiffeners;

$I_p = (\dfrac{h_w^3 t_w}{3} + h_w^2 b_f t_f) \times 10^{-4}$, for flanged secondary stiffeners;

I_t — St Venant's moment of inertia of the secondary stiffener without top flange, in cm^4:

$I_t = \dfrac{h_w t_w^3}{3} \times 10^{-4}$, for flat bar secondary stiffeners;

$$I_t = \frac{1}{3}[h_w t_w^3 + b_f t_f^3 (1 - 0.63\frac{t_f}{b_f})] \times 10^{-4}$$, for flanged secondary stiffeners;

h_w — web height of the secondary stiffener, in mm;

t_w — web net thickness of the secondary stiffener, in mm;

b_f — width of the secondary stiffener bottom flange, in mm;

t_f — net thickness of the secondary stiffener bottom flange, in mm;

s — spacing of secondary stiffeners, in m;

C — spring stiffness exerted by the hatch cover top plating, calculated by the following formula:

$$C = \frac{k_p E t_p^3}{3s(1 + \frac{1.33 k_p h_w t_p^3}{1000 s t_w^3})} \times 10^{-3};$$

$k_p = 1 - \eta_p$, to be taken not less than zero; for flanged secondary stiffeners, k_p need not be taken as less than 0.1;

$$\eta_p = \frac{\sigma}{\sigma_{E1}};$$

σ —normal stress of the attached plate of the wing plate of the primary supporting member;

σ_{E1} — as given in 2.20.3.5(1);

t_p — net thickness of the hatch cover plate panel, in mm.

Number of Half Waves (*m* value) **Table 2.20.3.5(2)**

K	$0 < K \leq 4$	$4 < K \leq 36$	$36 < K \leq 144$	$(m-1)^2 m < K \leq m^2(m+1)^2$
m	1	2	3	m

(3) Web panels of hatch cover primary supporting members critical stress

This check is to be carried out for the web panels of primary supporting members, formed by web stiffeners or by the crossing with other primary supporting members, the face plate (or the bottom cover plate) or the attached top cover plate.

The shear stress τ in the hatch cover primary supporting member web panels is not to exceed 0.8 times the critical buckling stress τ_c, to be evaluated as defined below:

$$\tau_c = \tau_E \quad \text{for } \tau_E \leq \frac{\tau_F}{2}$$

$$\tau_c = \tau_F (1 - \frac{\tau_F}{4\tau_E}) \quad \text{for } \tau_E > \frac{\tau_F}{2}$$

where: $\tau_F = \frac{R_{eH}}{\sqrt{3}}$ N/mm^2;

R_{eH} — yield stress of the material, in N/mm^2;

$$\tau_E = 0.9 k_t E \left[\frac{t_{pr,n}}{1000d} \right]^2 \quad \text{N/mm}^2;$$

E — modulus of elasticity, in N/mm^2, = 2.06×10^5 for steel;

$t_{pr,\,n}$ — net thickness of primary supporting member, in mm;

$$k_t = 5.35 + 4.0 \left(\frac{d}{a} \right)^2;$$

a — greater dimension of web panel of primary supporting member, in m;

d — smaller dimension of web panel of primary supporting member, in m.

For primary supporting members parallel to the direction of secondary stiffeners, the actual dimensions of the panels are to be considered.

For primary supporting members perpendicular to the direction of secondary stiffeners or for hatch covers built without secondary stiffeners, a presumed square panel of dimension d is to be taken for the determination of the stress τ_c. In such a case, the average shear stress τ between the values calculated at the ends of this panel is to be considered.

2.20.3.6 Steel pontoon covers are to be provided with tarpaulins and securing devices in accordance with the following requirements:

(1) At least two layers of tarpaulin in good condition are to be provided for each hatchway in exposed freeboard and superstructure decks.

(2) Tarpaulins are to be free from jute, and the minimum weight in unit area of the material before treatment is to be:

0.65 kg/mm^2, if the material is tarred;

0.65 kg/mm^2, if the material is chemically dressed;

0.55 kg/mm^2, if the material is dressed with black oil.

(3) Cleats are to be welded to the hatch coamings or the horizontal stiffeners, and the cleats are to be so set as to fit the taper of the wedges. The width of cleats is not to be less than 65 mm, and the cleats are to be spaced not more than 600 mm from centre to centre. The first and last cleats along each side or end are to be arranged not more than 150 mm from the hatch covers.

(4) Wedges are to be of tough wood. They are to have a taper of not more than 1 in 6 and are not to be less than 13 mm in thickness at the point.

(5) For all hatchways situated in exposed freeboard and superstructure decks, steel bars or other equivalent means are to be provided in order to efficiently secure each section of hatch covers after the tarpaulins are battened down. Hatch covers of more than 1.5 m in length are to be secured by at least two such securing appliances.

(6) For all hatchways situated in other exposed positions, ring bolts or other fittings for lashings are to be provided.

2.20.3.7 The hatch coamings of steel pontoon covers are to comply with the following requirements:

(1) Construction of exposed hatch coamings

① The thickness t of hatch coamings is not to be less than that obtained from the following formula:

$$t = 0.05L + 6.5 \quad \text{mm}$$

where: L— length of ship, in m, need not be greater than 90 m.

② Coamings of 600 mm or more in height are to be stiffened on their upper edges or at about 250 mm below the upper edge by a horizontal bulb flat or equivalent strength member. The web depth of the horizontal bulb flat is not to be less than 180 mm, and an additional support is to be afforded by fitting vertical stays or brackets from the bulb flat to the deck at intervals of not more than 3 m. The web depth of the stiffeners or brackets is to be not less than that of the horizontal bulb flat and they are to be flanged or fitted with a face plate. Where the coamings are more than 900 mm in height, the spacing of the above-mentioned stays or brackets is to be suitably reduced. Where the coamings are equal to or more than 1,200 mm in height, an additional horizontal bulb flat or equivalent strength member is to be fitted in way of half height of the coaming. Where the coamings are subject to loaded containers, the hatch coamings and their supporting members are to be strengthened correspondingly.

③ Where no face plate is fitted, the upper edges of coamings are to be stiffened by half round bars or other rolled bars to ensure the rigidity of coamings and the smoothness of their upper edges.

④ Where the deck plating does not extend inside the coamings, the coamings at the corners of hatchways are to be rounded. For openings within 0.5L amidships, the radius of the rounded corner is to comply with the requirements of 2.4.4 of this Chapter.

If the deck plating extends inside the coamings, the coamings at the corners of hatchways may be square provided that the corners of deck openings are in compliance with the requirements of 2.4.4 of this Chapter and that the longitudinal coamings at hatch corners are extended in the form of a tapered bracket.

⑤ Extension brackets or rails arranged approximately in line with the cargo hatch side coamings and intended for the stowage of steel covers are not to be welded to a deckhouse or masthouse, unless upon calculation it shows that the hatch coamings may be used as longitudinal strength members of the hull.

⑥ Where the exposed hatch coamings act as deck girders, they are also to comply with the relevant requirements of 2.8.8 of this Chapter.

(2) Where the 'tween deck hatch coamings act as deck girders, they are also to comply with the relevant requirements of 2.8.8 of this Chapter.

2.20.4 Hatch covers with portable beams

2.20.4.1 The design load of hatch covers with portable beams is to comply with the following requirements:

(1) The vertical weather design load of exposed hatch covers is to comply with Table 2.20.2.2(1) of this Section.

(2) The permissible cargo load on hatch covers is to comply with the requirements of 2.20.3.1(2) of this Section.

2.20.4.2 Hatch covers with portable beams are to be in compliance with the following requirements:

(1) Hatch covers with portable beams, where the cover is made of steel, are to meet the requirements of 2.20.3.2(1) of this Section; where the cover is made of wood, the thickness t is not to be less than that obtained from the following formula:

$$t = 40S \quad \text{mm, but in no case to be less than 60 mm}$$

where: S— spacing of portable hatch beams, in m.

Where the design load exceeds 18.4 kN/m^2, the thickness of wood covers is to be increased in direct proportion to the load.

Both ends of wood hatch covers are to be protected by encircling galvanized steel bands, about 65 mm wide and 3 mm thick, efficiently secured.

(2) Where the vertical design load is applied, the exposed hatch covers with portable beams are to comply with the following requirements:

① The section modulus W and the section moment of inertia I of the portable beams are not to be less than:

$$W = 0.782\,KSpl^2 \quad \text{cm}^3$$
$$I = 1.44\,Spl^3 \quad \text{cm}^4$$

where:

p — vertical weather design load, in kN/m^2, to be calculated according to 2.20.4.1 of this Section;

S — spacing of portable beams, in m;

l — span of portable beam, in m;

K — material factor.

② The ends of web plates are to be doubled, or inserts fitted for at least 180 mm along length of web.

③ The portable beams are to be stiffened at their upper and lower edges by continuous face plates. The width of the upper face plate is to be sufficient to provide a bearing surface of not less than 65 mm for hatch covers, and a vertical flat bar with a height of 50 mm is to be arranged on the upper face plate.

④ Carriers or sockets are to provide means for the efficient fitting and securing of portable hatch beams. The width of bearing surface is at least to be 75 mm.

⑤ The section modulus W and the section moment of inertia I of stiffeners of steel covers are not to be less than:

$$W = 0.664Kspl^2 \quad \text{cm}^3$$
$$I = 1.13spl^3 \quad \text{cm}^4$$

where:

p — vertical weather design load, in kN/m^2, to be calculated according to 2.20.4.1 of this Section;

l — span of stiffener, in m;

s — spacing of stiffeners, in m;

K — material factor.

(3) Where the uniformly distributed cargo load is applied, the hatch covers with portable beams are to comply with the following requirements:

① The section modulus W and the section moment of inertia I of portable beams are not to be less than:

$$W = 1.064KSpl^2 \quad \text{cm}^3$$
$$I = 1.8Spl^3 \quad \text{cm}^4$$

where:

p — permissible cargo load, in kN/m^2;

S — spacing of portable beams, in m;

l — span of portable beam, in m;

K — material factor.

② Portable beams are also to comply with the requirements of 2.20.4.2(2)② to ④.

③ The section modulus W and the section moment of inertia I of portable beams are not to be less than:

$$W=1.064Kspl^2 \quad \text{cm}^3$$

$$I=1.8spl^3 \quad \text{cm}^4$$

where:

p — permissible cargo load, in kN/m^2;

l — span of portable beam, in m;

s — spacing of portable beams, in m;

K — material factor.

(4) The scantling of stiffeners and girders with a variable cross-section for hatch covers with portable beams are to comply with the requirements of 2.20.3.2(3) of this Section.

2.20.4.3 The direct strength calculation of hatch covers with portable beams is to comply with the requirements of 2.20.2.4 of this Section.

2.20.4.4 The yield strength and deformation of hatch covers with portable beams is to comply with the requirements of 2.20.3.4 of this Section.

2.20.4.5 The buckling strength of hatch covers with portable beams is to comply with the requirements of 2.20.3.5 of this Section.

2.20.4.6 The closing appliances of hatch covers with portable beams are to comply with the requirements of 2.20.3.6 of this Section.

2.20.4.7 The hatch coamings of hatch covers with portable beams are to comply with the requirements of 2.20.3.7 of this Section.

2.20.5 Miscellaneous openings

2.20.5.1 Miscellaneous openings are to comply with the requirements of 1.12.7 of Chapter 1 of this PART.

2.20.5.2 Small hatchways on exposed decks are also to comply with the following requirements:

(1) The height of coamings of small hatchways is to comply with the requirements of 2.20.1.8 of this Section. The thickness of the coamings is not to be less than the minimum thickness as required in this Chapter for the deck inside the line of openings for that position, or 11 mm, whichever is the lesser;

(2) Small hatchways are to be provided with steel weathertight hatch covers and reliable securing devices. The means of securing are to be such that weathertightness can be maintained in any condition. The thickness of the hatch covers is not to be less than the minimum thickness required by this Chapter for the deck inside the line of openings for that position, or 8 mm, whichever is the lesser;

(3) Strength and securing of small hatches on the exposed fore deck are also to comply with the relevant requirements of Section 7, Chapter 1 of this PART.

Section 21 VEHICLE DECKS

2.21.1 General requirements

2.21.1.1 Where wheeled vehicles are to be stowed on the deck or used for cargo handling, the scantlings of the deck or hatch covers are to comply with the relevant requirements in this PART and in addition, are to be checked for strength in accordance with the requirements of this Section.

2.21.1.2 Where wheeled vehicles are to be stowed on the inner bottom or used for cargo handling, the strength of inner bottom plating in way may also be checked by reference to the requirements of this Section.

2.21.2 Deck plating

2.21.2.1 The thickness of deck plating is to comply with the following requirements:

(1) The thickness t of deck plating is not to be less than that obtained from the following formula:

$$t = CJ\sqrt{PK} + 1.5 \quad \text{mm}$$

where: P — load, in t, on the tyre print. Two closely spaced wheels may be regarded as a combined wheel print and the sum of loads on both tyre prints is to be taken;

K — material factor;

C, J — coefficients, to be calculated as follows:

For $0.5 \leq \frac{u}{v} < 1$:

$$J = 0.73(0.85 - \frac{u}{v}) + \frac{4.58}{\frac{v}{s} + 0.62}$$

$$C = 1 - (0.099\frac{v}{s} + 0.013)(2.5 - \frac{l}{s})$$

For $1 \leq \frac{u}{v} < 2$:

$$J = 0.51(0.79 - \frac{u}{v}) + \frac{4.58}{\frac{v}{s} + 0.62}$$

$$C = 1 - (0.156\frac{v}{s} + 0.009)(2.5 - \frac{l}{s})$$

For $2 \leq \frac{u}{v} < 3$:

$$J = 0.4(0.66 - \frac{u}{v}) + \frac{4.30}{\frac{v}{s} + 0.57}$$

$$C = 1 - (0.196\frac{v}{s} + 0.013)(2.5 - \frac{l}{s})$$

where: $\frac{u}{v}$ — aspect ratio of tyre print, see Figure 2.21.2.1(1). For 2 tyre prints on one plate panel, see Figure 2.21.2.1(2), $u' = 2u$; where $\frac{u'}{v} \geq 3$, calculating by $u_1 = v_1 = \sqrt{u'v}$;

l — span of frames, in m;

s — spacing of frames, in m;

when $l/s > 2.5$, to be taken as 2.5.

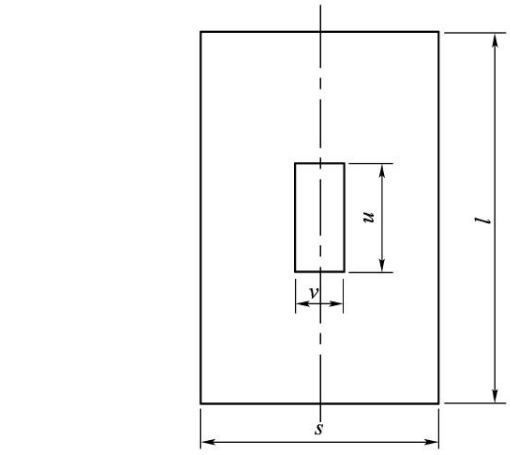

Figure 2.21.2.1(1)

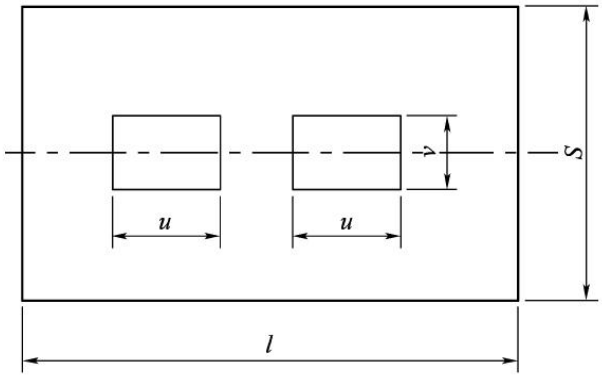

Figure 2.21.2.1(2)

(2) Where forklift trucks are to be used for cargo handling on decks and no data for tyre print and deadweight, etc., are available, the thickness of deck plating may be obtained in accordance with the following formula:

$$\frac{s}{t} \leq \frac{111}{P+1} + 27$$

where: t — thickness of deck plating, in mm;

s — spacing of deck longitudinals or beams, in mm;

P — cargo weight lifted by the forklift truck, in t.

(3) Where wheeled vehicles are to be stowed or used on insulated decks, attention is to be paid to the effect on the insulation coating due to deck deformation when the permissible loading of decks is determined based on the thickness of deck plating.

2.21.2.2 The section modulus of deck beams and longitudinals are to comply with the following requirements:

(1) Where forklift trucks are to be used for cargo handling on cargo deck, the section modulus W of deck beams or longitudinals is not to be less than that obtained from the following formula:

$$W = (0.375J_1Pl + 1.25J_2hsl^2)K \quad \text{cm}^3$$

where: P — total weight of forklift truck, in t;

h — design head on the deck, in m, see 2.8.1.1 of this Chapter;

s — spacing of frames, in m;

l — span of frames, in m;

K — material factor;

J_1, J_2 — coefficients, to be taken according to Table 2.21.2.2.

Coefficients J_1 and J_2 **Table 2.21.2.2**

J	0.1	0.2	0.3	0.4	0.5 and over
J_1	15.4	14.6	13.35	11.8	10.1
J_2	1.89	1.85	1.73	1.55	1.30

Note: J = wheel spacing/span of frame, where wheel spacing is to be taken as the spacing between the two outermost wheels on the same axle.

(2) Where decks are permanently intended for the carriage of vehicles, the section modulus W of deck beams or longitudinals is not to be less than that obtained from the following formula:

$$W = (0.536J_1Pl + 1.25J_2shl^2)K \quad \text{cm}^3$$

where: P — load on one axle, in t, i.e. total weight of the vehicle divided by the number of axles. Where the distribution of weight is not uniform, P is to be taken as the maximum axle load;

h — design head on deck, in m, in accordance with 2.8.1.1 of this Chapter, but h need not be more than 2.5 m;

s — spacing of frames, in m;

l — span of frames, in m;

K — material factor;

J_1, J_2 — coefficients, to be taken according to Table 2.21.2.2.

(3) In addition to the above-mentioned requirements, the strength of deck beams or lonitudinals is to be checked according to the following requirements: the allowable bending stress is not to exceed $104/K$, in N/mm² if it is assumed that both ends of beams or longitudinals are fixed rigidly and that the beam is only subjected to the concentrated load of wheels.

2.21.2.3 The section modulus of deck transverses or girders is to comply with the following requirements:

(1) Where the deck transverses or girders are subject to uniformly distributed loading, the section modulus W is not to be less than that obtained from the following formula:

$$W = 4.75bhl^2K \quad \text{cm}^3$$

where: b — spacing of transverses or girders, in m;

l — span of transverse or girder, in m;

h — design head on deck, in m, in accordance with 2.8.1.1 of this Chapter;

K — material factor.

(2) Where the deck girders or transverses are subject to concentrated loads, with or without the addition of uniformly distributed load, the section modulus is to be determined by calculations. During the calculation, 100% end fixity is to be assumed, and the permissible bending stress is to be taken as $118/K$, in N/mm².

2.21.3 Hatch covers

2.21.3.1 Where wheeled vehicles are to be stowed or used for cargo handling on hatch covers, the thickness of hatch cover plating is to comply with the provisions in 2.21.2.1 of this Section.

2.21.3.2 Where wheeled vehicles are to be stowed or used for cargo handling on hatch covers, the section modulus W of hatch cover stiffeners is not to be less than that obtained from the following formula:

$$W = (J_3Pl + 1.67J_4shl^2)K \quad \text{cm}^3$$

where: P — load on one axle, in t, see 2.21.2.2 of this Section;

h — design head on the hatch cover, in m; $h = 0.14\,p$, where p is the vertical weather design load on the hatch cover given in 2.20.2.2(1) of this Chapter;

s — spacing of stiffeners, in m;

l — span of stiffener, in m;

K — material factor;

J_3, J_4 — coefficients, to be taken according to Table 2.21.3.2.

Coefficients J_3 and J_4 **Table 2.21.3.2**

J	0.1	0.2	0.3	0.4	0.5	0.6	0.7	0.8	0.9
J_3	11.96	10.69	9.58	8.46	7.46	6.51	5.55	4.23	2.38
J_4	2.32	1.89	1.55	1.28	1.07	0.91	0.73	0.36	0.11

Note: J = wheel spacing/span of stiffeners, where wheel spacing is to be taken as the spacing between the two outermost wheels on the same axle.

Section 22 STRENGTHENED FOR HEAVY CARGOES

2.22.1 General requirements

2.22.1.1 Ships complying with the requirements of this Section will be assigned the class notation: Strengthened for Heavy Cargoes.

2.22.1.2 Ships of loading rate γ not greater than 0.833m^3/t (see 1.1.2.15 of Chapter 1) are to comply with the requirements of this Section, except when loaded by steel coils on a wooden support.

2.22.1.3 Special considerations are to be given to the strengthening requirements where the inner bottom plating of the cargo hold is loaded by bulky cargo or bearing concentrated load.

2.22.2 Requirements for hull structures

2.22.2.1 The strength deck and bottom in way of cargo holds are to be framed longitudinally, and the ship is to be provided with a double bottom within the region of cargo spaces.

2.22.3 Strengthening of bottom framing

2.22.3.1 The plate floors are generally to be spaced not more than 2.5 m apart, and the thickness of the floors is not to be less than that required in 2.6.11.2 of this Chapter.

2.22.3.2 The bottom girders are generally to be spaced not more than 3.6 m apart, and the thickness of side girders is not to be less than that required in 2.6.10.2 of this Chapter.

2.22.3.3 The thickness of watertight or oiltight floors is to comply with the requirements of 2.6.11.2 of this Chapter.

2.22.3.4 The thickness t of inner bottom plating is not to be less than that obtained from the following formulae:

$$t = (0.04L + 5s + 1.1)\sqrt{K} + 5 \qquad \text{mm}$$

$$t = 4.65s\sqrt{\frac{HK}{\gamma}} \qquad \text{mm}$$

where: L — length of ship, in m, L need not be taken greater than 400 m;

s — spacing of inner bottom longitudinals, in m;

γ — stowage rate, in m³/t, but not to be greater than 0.833;

H — vertical distance, in m, measured from the inner bottom plating to deck at side amidships;

K — material factor.

2.22.3.5 The section modulus W of inner bottom longitudinals is not to be less than 85% of that of bottom longitudinals as required in 2.6.12.2 of this Chapter, nor to be less than that obtained from the following formula:

$$W = \frac{8.5}{\gamma} Hsl^2 K \quad \text{cm}^3$$

where: γ, H and s — same as defined in 2.22.3.4 of this Section;

l — span of inner bottom longitudinal, in m;

K— material factor.

2.22.3.6 Where vertical stays are fitted in way of the mid-span of inner bottom longitudinals and the inner bottom longitudinals are subject to uniformly distributed loading, the scantlings of bottom longitudinals and stays may be determined by direct calculations.

2.22.3.7 The construction of the duct keel is to comply with the requirements of 2.6.3 of this Chapter. But the section modulus W of the inner bottom stiffening members is not to be less than the values derived from 2.22.3.5 of this Section, and in this case s is the spacing of the stiffening members, in m, and l is the span of stiffening members, in m.

Section 23 STRENGTHENING FOR GRABS

2.23.1 General requirements

2.23.1.1 This Section applies to ships intended to carry dry cargo in bulk, and include such types as bulk carriers, ore carriers and combination carriers.

2.23.2 Class notation

2.23.2.1 The class notation Grab*(X) is assigned to ships with holds designed for loading/unloading by grabs having a maximum specific weight up to X tons, in compliance with the requirements of this Section.

2.23.3 Structural strengthening

2.23.3.1 The thickness t_{GR}, in mm, of the inner bottom plating is not to be less than that obtained from the following formula:

$$t_{GR} = 0.28(M_{GR} + 50)\sqrt{sK} + 5.0 \quad \text{mm}$$

where: M_{GR} — mass of unladen grab, in tons;
s — spacing, in m, of ordinary stiffeners, measured at mid-span;
K — material factor.

2.23.3.2 The thickness t_{GR}, in mm, of hopper tank sloping plate, transverse lower stool, transverse bulkhead plating and inner hull up to a height of 1.5 m above the lowest point of the inner bottom, excluding bilge wells, is to be not less than the value obtained from the following formula:

$$t_{GR} = 0.28(M_{GR} + 42)\sqrt{sK} + 3.5 \quad \text{mm}$$

where: M_{GR} — mass of unladen grab, in tons;
s — spacing, in m, of ordinary stiffeners, measured at mid-span;
K — material factor.

Section 24 ANALYSIS OF TEMPERATURE FIELD AND THERMAL STRESS OF CARGO TANK STRUCTURE

2.24.1 General requirements

2.24.1.1 This Section applies to ships carrying liquefied gases in bulk, ships carrying dangerous liquid chemicals having a temperature higher than 80℃ at atmospheric pressure in bulk, oil tankers and asphalt carriers, and contains specific requirements for cargo tank thermal stress calculation as required in Chapter 10, PART EIGHT of the Rules, Chapter A4 of CCS Rules for Construction and Equipment of Ships Carrying Dangerous Liquid Chemicals in Bulk, Chapter A4, PART TWO of CCS Rules for Construction and Equipment of Ships Carrying Liquefied Gases in Bulk, and other relevant rules of CCS.

2.24.1.2 Unless approved by CCS, the following two loading modes are not to be used:

(1) cargoes of different temperatures and natures are carried simultaneously in adjacent tanks or in the cargo tank area;

(2) liquid cargo and ballast water of high (low) temperature are carried simultaneously in cargo tanks and adjacent ballast tanks.

2.24.1.3 In this Section, the thermal stress calculation for cargo tanks include two steps which are to be performed in sequence. At step 1, the distribution of temperature field of cargo tanks and associated structures is to be obtained through heat transferring analysis with the given temperatures of hot/cold sources of liquid cargo and the given ambient temperatures. Step 2 is to use the distribution of temperature field so obtained as input condition for thermal analysis, so as to obtain the thermal-expansion-induced thermal stress of any structure in the temperature field due to temperature difference.

2.24.1.4 The heat transferring calculation in this Section is based on an assumed steady state heat transferring in three-dimensional space, no change of material parameters and boundary

conditions is made in conjunction with any temperature change in the analysis of linear heat transferring, and only the effects of transferring through structures and insulation are considered.

2.24.1.5 The thermal calculation in this Section is based on the assumption of a "sequentially coupled heat-structure (sequentially coupled problem)", i.e., the effects of changes in the temperature field on the machinery field are considered without taking account of the effects of the latter on the former. Moreover, the high temperature creeping effects of structures are not considered.

2.24.1.6 In calculation, it is assumed that heat is transferred between hull structural members by conduction, and that heat exchange between air and hull structural members exposed to it is natural convection only.

2.24.1.7 In heat transferring calculation and thermal stress analysis, recognized finite element thermal analysis programs and finite element structural analysis programs are to be used.

2.24.1.8 Where methods or assumptions other than those specified in the Rules are to be used in calculation, they are to be approved by CCS.

2.24.2 Plans and documents

2.24.2.1 In addition to calculations as generally required by relevant CCS documents for direct finite element structural calculation, the following heat transferring calculation and thermal stress analysis documents together with associated drawings and documents are to be submitted:

(1) Arrangement of insulation layers and details of their connection;

(2) Thermal parameters of insulation layers (coefficient of thermal conductivity, etc.);

(3) Heat balance calculation and analysis report, including the following:

a. maximum design temperature of liquid cargo to be carried (the temperature indicated in class notation);

b. design target values of external surface temperature of steel plating of inner side, inner bottom and deck, if any;

c. lowest/highest ambient temperature (atmosphere and seawater) for intended operating route;

d. distribution of temperature field under consideration.

(4) Thermal stress calculation report: thermal stress calculation based on the distribution of temperature field as obtained according to (3) and performed according to this Section, including check of resultant stresses for combinations of thermal stress with corresponding sea conditions and loading conditions.

2.24.3 Model for analysis

2.24.3.1 Scope of model: For integral tanks, it is to be in accordance with the requirements of Appendix 1, Chapter 5 of this PART. If necessary (temperature gradient is large), modeling of the fore end area of the foremost cargo tank and that of the aft end area of the aftermost cargo tank are to be considered. For independent tanks, at least the entire tank structure is to be taken. For the effects of temperature on the supporting structure of cargo tanks and on the hull, see the relevant requirements of Appendix 1, PART TWO of CCS Rules for Construction and Equipment of Ships Carrying Liquefied Gases in Bulk. For heat transferring analysis, the model is to cover all contributing heat insulation materials and structures, except that stainless liner may be neglected; for thermal stress analysis, the model is merely a structural one.

2.24.3.2 Structural elements: The principled requirements for modeling in respect to types of elements and meshing, etc., are as given in Appendix 1, Chapter 5 of this PART.

2.24.3.3 Insulation elements: For rock wool thermal insulation, the elements are generally of solid-element type, thickness is taken as that of the insulation layer (excluding stainless liner), and other principles for modeling, e.g. element type selection and meshing, are similar to those for structures. However, simplification is allowed, as appropriate, in way of complex intersection of certain structures (insulation), e.g. connection of a longitudinal or transverse corrugated bulkhead with upper stool.

2.24.3.4 Boundary conditions for heat transferring analysis:

(1) The thermal transferring analysis for the determination of steel grades required for structural materials used at low temperatures is to be in accordance with the following requirements:

a. For ships carrying dangerous chemicals in bulk, to which CCS Rules for Construction and Equipment of Ships Carrying Dangerous Liquid Chemicals in Bulk apply and for which thermal stress calculation is to be performed, the boundary conditions regarding external atmospheric temperature and seawater temperature are to be taken in accordance with Chapter A4 of CCS Rules for Construction and Equipment of Ships Carrying Dangerous Liquid Chemicals in Bulk. For ships carrying liquefied gases in bulk, to which CCS Rules for Construction and Equipment of Ships Carrying Liquefied Gases in Bulk apply and for which thermal stress calculation is to be performed, the boundary conditions regarding external atmospheric temperature and seawater temperature are to be taken in accordance with Chapter A4, PART TWO of CCS Rules for Construction and Equipment of Ships Carrying Liquefied Gases in Bulk.

b. For ships not covered by a. above, the boundary conditions regarding external atmospheric temperature and seawater temperature are as follows:
portions of hull below draught line – the defined surface temperature is the lowest temperature in water and if icing is possible for the intended operating route, this temperature is to be taken as 0°C;
portions of hull above draught line – the defined surface temperature is the possibly lowest atmospheric temperature for the intended operating route, e.g. -20°C.

(2) In respect to the determination of maximum thermal stress, the temperature load condition applied as input for the thermal analysis is to be the maximum difference between the liquid cargo temperature and the ambient temperature for the intended operating route.

(3) For the side of cargo tank insulation or bare structural shell which is in direct contact with liquid cargo, the defined surface temperature is the highest stable temperature of liquid cargo being carried.

(4) For the space within double bottom and double side skin, the ambient temperature may be directly taken a little higher than the external temperature, and the assumed convective heat transfer between air and steel plating as mentioned above (heat transferring by air is assumed to be little) is defined in respect to external surfaces of inner side shell and inner bottom (the surfaces not exposed to liquid cargo). Alternatively, this space may be taken as a three-dimensional finite element model of air elements and incorporated into the finite element heat transferring model. The heat transferring calculation is performed according to the assumption of 2.24.1.6, without taking account of the heat transferring by air. Where there are special requirements for the highest temperature criterion regarding periphery of cargo tanks, the surface temperature is to be defined as so required.

(5) The external surface temperature of the independent tank structure is to be defined according to the above requirements, as applicable.

(6) The gas temperature in cargo tanks in the half-loaded condition may be assumed as the liquid cargo temperature, and the boundary conditions for heat convection of gas are to be used to simulate the effects of gas on structure.

2.24.3.5 In thermal analysis, the structural boundary conditions for the integral tank model are to be in accordance with the requirements of Appendix 1, Chapter 5 of this PART. For independent tanks, the model structural boundary conditions are to be taken as those for the loading conditions corresponding to temperature loads. In addition, restraint of linear displacement δ_x in the direction of ship's length is to be released at a certain end (e.g. end B) of section model for the structural boundary condition of above model.

2.24.4 Thermal calculation and loading conditions

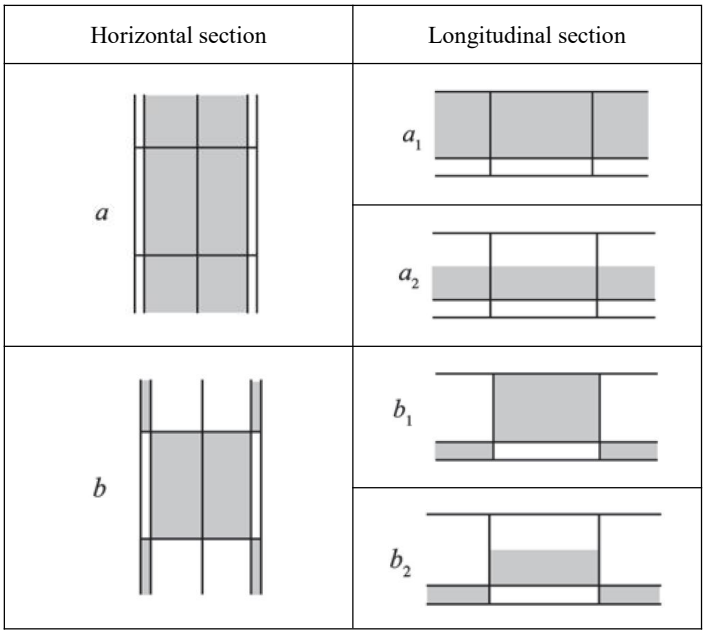
2.24.4.1 The distribution values of the three-dimensional temperature field obtained from heat transferring analysis are to be used as temperature loads in structural strength calculation. For tankers as stipulated in the Rules, where independent tanks are fitted, temperature loads in the full load condition are to be calculated; where integral tanks are fitted, the load conditions are to be as shown in Figure 2.24.4.1, and the following are to be complied with:

(a) — only sagging mode is considered;

(b), (c) — sagging and hogging modes are considered respectively.

And for (a), (b) and (c), both full and half load conditions in the above modes are to be considered. The half load condition means the loading height of liquid cargo is half the height of tank.

Where any loading condition specified in the loading manual or occurring in service is worse than the above conditions under consideration, the temperature load calculated to such loading condition is to be included. For cargo tanks of other ship types, temperature loads in relevant loading conditions are to be calculated in accordance with the requirements of the applicable rules.



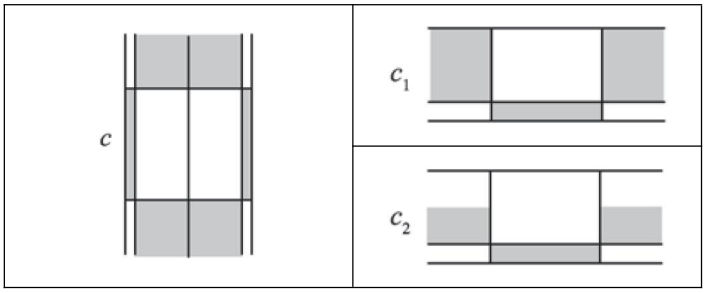


Figure 2.24.4.1

2.24.4.2 The temperature loads as calculated above are to be applied to the model of each corresponding loading condition. The calculation and application of routine loading conditions are to follow the applicable requirements in Appendix 1, Chapter 5 of this PART, Appendix 1 and Appendix 2 of PART TWO of CCS Rules for Construction and Equipment of Ships Carrying Liquefied Gases in Bulk and other relevant documents or routine practice.

2.24.4.3 Where only longitudinal tension and compression stresses less than $42/K$ N/mm^2 (K being material factor) are applied in regard to thermal stresses induced by temperature loads, the longitudinal bending moment of hull girder may not to be applied to both ends of the model under consideration, subject to agreement of CCS.

2.24.4.4 The heat conduction coefficient and linear expansion coefficient of steel as well as the convective heat exchange coefficient of air are to be provided by designer. For asphalt carriers during preliminary design, reference may be made as follows:

Heat conduction coefficient of carbon steel: 60.6 W/(m·K) – for heat transferring calculation (thermal analysis);

Linear expansion coefficient of carbon steel: 11×10^{-6}(1/K) – for heat stress calculation (structural analysis);

Convective heat exchange coefficient of air: 11.6 W/(m^2·K) – for heat transferring calculation (thermal analysis). Where the length of the finite element model is measured in mm, the value taken is to be multiplied by 10^{-6}.

The heat conduction coefficient for insulation material is to be taken according to the actual design.

2.24.5 Strength criteria

2.24.5.1 For an integral tank model, the criteria are as given in Appendix 1, Chapter 5 of this PART; for hull portion of an independent tank model, the criteria are as given in Appendix 1 and Appendix 2 of PART TWO of CCS Rules for Construction and Equipment of Ships Carrying Liquefied Gases in Bulk; for construction materials of independent tanks of petroleum asphalt carriers, the criteria are as given in Section 2 of Chapter 10, PART EIGHT of the Rules.

2.24.5.2 Where wave loads are obtained by direct calculation on the basis of dynamic loading, the permissible stress taken according to 2.24.5.1 may be multiplied by 1.1 and the minimum buckling safety factor may be multiplied by 0.9.

2.24.5.3 For a finite element model, for which the longitudinal hull girder bending moment is not taken into account, the permissible stress is to be adjusted as follows on the basis of Appendix 1, Chapter 5 of this PART, without any change to other requirements:

For all plating $[\sigma_e] = 175/K$

For longitudinal plating $[\sigma_l] = 110/K$

For longitudinal girders $[\tau] = 83/K$

For transverse members (including floors, transverse bulkheads) $[\tau] = 93/K$

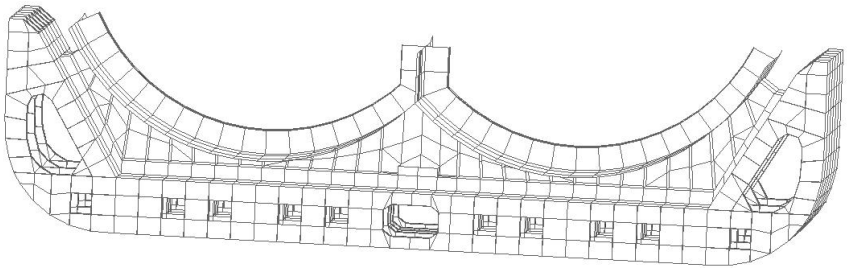
where: K — material factor.

2.24.6 Inner liner or membrane

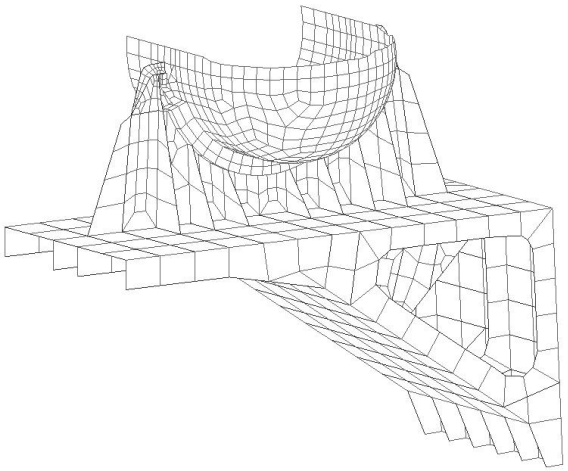
2.24.6.1 For an integral tank model, consideration is to be given to using suitable elastic joints and slightly movable riveting means to eliminate or reduce its inner stressing and deformation due to temperature-induced expansion or contraction of the inner liner or membrane, ensuring that the thermal stress of the inner liner or membrane will not exceed the permissible value and that the deformation will not cause any damage to the function of insulation layers.

2.24.7 Analysis of temperature field for supporting structures of independent tank

2.24.7.1 The finite element model for analysis of temperature field includes supporting structure and its connected hull structure as well as indpendnent tank structure.



(1) Finite element model for analysis of temperature filed of supporting strucutre of independent tank



(2) Finite element model for analysis of temperature field of supporting structure of deck tank

Figure 2.24.7.1 Finite Element Model of Supporting Strucutre of Independent Tank

2.24.7.2 The types of elements and meshing for structural finite element model are to meet the relevant requirements of Section 5, Chapter 1 of this PART of the Rules.

2.24.7.3 Geometry element, generally hexahegdron element is to be used for laminiated wood structure.

2.24.7.4 The longitudinal range of model is to include spacing of each web frame before or after supporting structure, the transverse range is to be taken as the width of ship (for deck tank, to be taken as the overall width of supporting structure), the vertical range is to be taken as the distance from the bottom of ship to the top of supporting structure (for deck tank, to be taken as the distance from deck structure to the top of supporting structure).

2.24.7.5 Boundary conditions for heat transferring analysis of hull structure connected with supporing structure are to be in accordance with the 2.24.3.4 of this Section, those for independent tank connected with supporting structure are to be taken as the temperature of liquid cargo, and those for supporting structure exposed in air are to be taken as the conditions for convective heat transfer, see Figure 2.24.7.5.

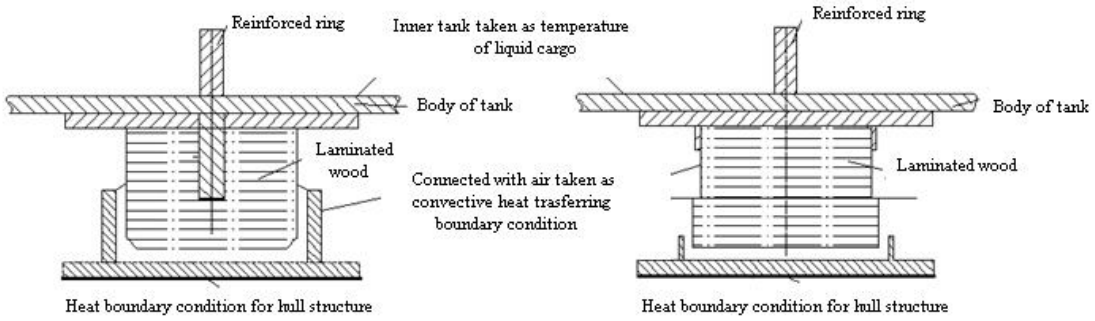


Figure 2.24.7.5 Diagram of Boundary Conditions for Analysis of Temperature Field of Supporting Structures

2.24.7.6 For material properties and air convection coefficient of model, see the relevant requirements of 2.24.4.4 of this Section.

2.24.7.7 The analysis of temperature field is to at least include the ambient temperature conditions specified in Chapter 4, PART THREE of CCS Rules for Construction and Equipment of Ships Carrying Liquefied Gases in Bulk.

Section 25 STRUCTURAL STRENGTHENING LOADED BY STEEL COILS ON A WOODEN SUPPORT

2.25.1 General requirements

2.25.1.1 The thickness of inner bottom plating, bilge hopper sloping plate and inner hull plating up to a height not less than the one corresponding to the top of upper tier in touch with hopper or inner hull plating as well as section modulus and shear area of stiffeners for ships intended to carry steel coils are to comply with the requirements of this Section.

2.25.1.2 The provision is determined based on the assumption of Figure 2.25.1.2 as the standard means of securing steel coils on the dunnage.

2.25.1.3 All steel coils are presumed to be of the same characters.

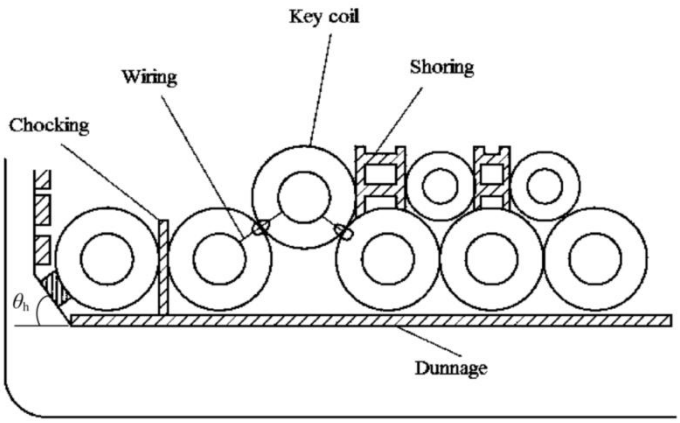

Figure 2.25.1.2 Inner Bottom Loaded by Steel Coils

2.25.2 Accelerations

2.25.2.1 In order to calculate the accelerations, the following coordinates are to be used for the transverse and vertical positions of calculated point:

$$y_{G-SC} = \begin{cases} B_h/4 & \text{for port} \\ -B_h/4 & \text{for starboard} \end{cases}$$

$$z_{G-SC} = h_{DB} + \left\{1 + (n_1 - 1)\frac{\sqrt{3}}{2}\right\}\frac{d_{SC}}{2}$$

where: B_h — breadth in m, at the mid of the hold, of the cargo hold at the level of connection of bilge hopper plate with side shell or inner hull;

d_{sc} — diameter of steel coils, in m;

h_{DB} — depth of double bottom, in m.

Vertical acceleration a_v, in m/s^2, are to be calculated by the formulae defined in 1.5.2 of Section 5, Chapter 1 of this PART and tangential acceleration a_R due to roll, in m/s^2, is to be calculated by the following formula:

$$a_R = \varphi_m \left(\frac{2\pi}{T_R}\right)^2 \sqrt{y_{G-SC}{}^2 + R^2}$$

where: φ_m, maximum angle of roll, T_R, roll period — see the formulae defined in 1.5.2 of Section 5, Chapter 1 of this PART**;**

$$R = z_{G-SC} - \min\left(\frac{D}{4} + \frac{d}{2}, \frac{D}{2}\right)$$

where: d — draught, in m.

2.25.3 Inner bottom plating

2.25.3.1 The thickness of plating of longitudinally framed inner bottom is not to be less than the value obtained, in mm, from the following formula:

$$t = K_1\sqrt{\frac{(g + 0.5a_v)F_{SC}}{\lambda_p R_{eH}}} + t_c \quad \text{mm}$$

where: K_1— coefficient taken equal to:

$$K_1 = \sqrt{\frac{1.7slK_2 - 0.73s^2K_2^2 - \left(l - l'\right)^2}{2l'\left(2s + 2lK_2\right)}}$$

t_c — corrosion addition, in mm, generally taken 2.5 mm, to be taken 5 mm where the cargo holds are designed for loading/unloading by grabs;

a_v — vertical acceleration, in m/s^2, calculated according to the formula defined in 1.5.2, Section 5, Chapter 1 of this PART;

g — acceleration due to gravity, g = 9.81 m/s^2;

F_{SC}— equivalent mass of steel coils, in kg, taken equal to:

$$F_{SC} = K_S \frac{W_{SC} n_1 n_2}{n_3}$$

λ_p— permissible bending stress coefficient of plating, generally taken 0.8, to be taken 0.9 as the calculated structural member is not contributing to the hull girder longitudinal strength;

l — length of long edge of elementary plate panel taken along the side length, in m;

s — length of short edge of elementary plate panel taken along the side length in way of middle of span l, in m;

K_s— coefficient, taken equal to:

K_s =1.4 when steel coils are lined up in one tier with a key coil;

K_s =1.0 in other cases;

W_{SC}— mass of one steel coil, in kg;

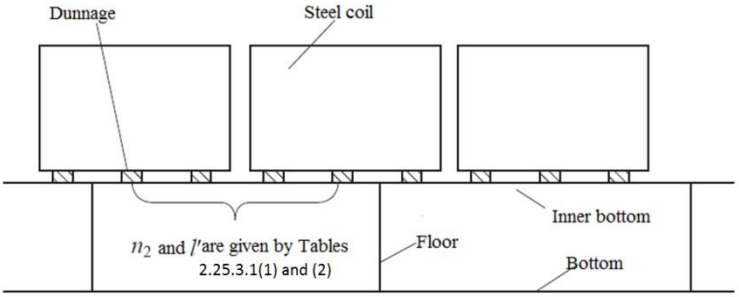
R_{eH} — minimum yield stress of material, in N/mm^2;

n_1— number of tiers of steel coils;

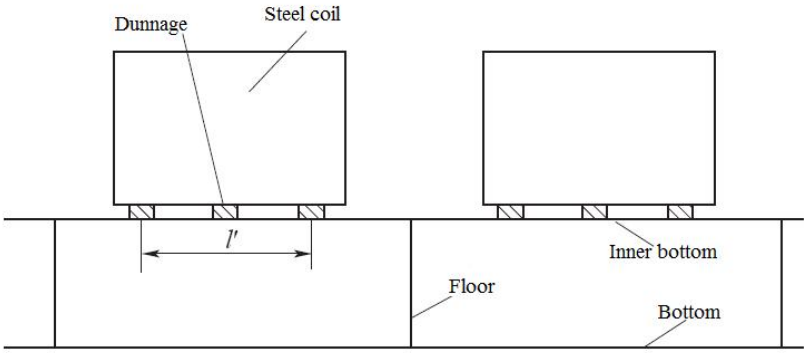
n_2— number of load points per elementary plate panel of inner bottom (see Figure 2.25.3.1). For steel coil loading related to floor plates of inner bottom (see Figure 2.25.3.1(2)), $n_2 = n_3$; for steel coil loading irrelevant to floor plates of inner bottom (see Figure 2.25.3.1(1)), n_2 is to be consistent with Table 2.25.3.1(1). For cases not included in Table 2.25.3.1(1), n_2 is to be determined in accordance with the following formula:

$$\frac{n_2 - 1}{n_3} + INT\left(\frac{n_2 - 1}{n_3}\right) \cdot 0.2 < \frac{l}{l_s} \le \frac{n_2}{n_3} + INT\left(\frac{n_2}{n_3}\right) \cdot 0.2$$

where: $INT(\ )$ is the integral function, taking the integral parts of values.



(1)



(2)

Figure 2.25.3.1 Loading Condition of Steel Coils

n_3 — number of dunnages supporting one steel coil;

l_s — length of a steel coil, in m;

K_2 — coefficient taken equal to:

$$K_2 = -\frac{s}{l} + \sqrt{\left(\frac{s}{l}\right)^2 + 1.37\left(\frac{l}{s}\right)^2\left(1-\frac{l'}{l}\right)^2 + 2.33}$$

l' — distance, in m, between outermost load points per elementary plate panel in ship's length (see Figure 2.25.3.1). For steel coil loading related to floor plates of inner bottom (see Figure 2.25.3.1(2)), l' is to be the distance between the dunnages of the external ends supporting the steel coils; for steel coil loading irrelevant to floor plates of inner bottom (see Figure 2.25.3.1(1)), l' is to be consistent with Table 2.25.3.1(2). For cases not included in Table 2.25.3.1(2), l' is to be determined in accordance with the following formula:

$$l' = \left[\frac{n_2 - 1}{n_3} + 0.2 \cdot INT\left(\frac{n_2 - 1}{n_3}\right)\right] l_s$$

where: $INT(\ )$ is the integral function, taking the integral parts of values.

2.25.4 Bilge hopper sloping plate and inner hull plate

2.25.4.1 The thickness of plating of longitudinally framed bilge hopper sloping plate and inner hull is not to be less than the value obtained, in mm, from the following formula:

$$t = K_1\sqrt{\frac{a_{hopper}F'_{SC}}{\lambda_p R_{eH}}} + t_c \quad \text{mm}$$

where: K_1— coefficient, defined in 2.25.3;

t_c ——corrosion addition, in mm, generally taken 2.5 mm, to be taken 3.5 mm for bilge hopper sloping plate and inner hull plate within 1.5 m height from the lowest point of inner bottom where the cargo holds are designed for loading/unloading by grabs;

R_{eH} — minimum yield stress of material, in N/mm^2;

a_{hopper}— factor taken equal to:

$$a_{hopper} = -a_R \sin\left(\tan^{-1}\left|\frac{y_{G-SC}}{R}\right| - \theta_h\right) + g\cos\left(\theta_h - \varphi_m\right)$$

θ_h — angle, in degree, between inner bottom plate and bilge hopper sloping plate or inner hull plate, see Figure 2.25.1.2;

φ_m — in degree, see formula specified in 1.5.2 of Section 5, Chapter 1 of this PART;

a_R— tangential acceleration defined in 2.25.2;

g — acceleration due to gravity, g = 9.81 m/s^2;

y_{G-SC}— centre of gravity in transverse direction, in m, defined in 2.25.2;

R— factor, defined in 2.25.2;

F'_{SC}—equivalent mass of steel coils, in kg, taken equal to:

$$F'_{SC} = C_k \cdot \frac{W_{SC} n_2}{n_3}$$

λ_p—permissible bending stress coefficient of plating, defined in 2.25.3;

C_k— coefficient, taken equal to:

C_k =3.2, when steel coils are lined up two or more tier, or when steel coils are lined up one tier and key coil is located second or third from bilge hopper sloping plate or inner hull plate;

C_k =2.0, in other cases.

2.25.5 Stiffeners of inner bottom

2.25.5.1 The section modulus W and the shear area A of single span stiffeners located on inner bottom plating are not to be less than the values obtained from the following formulae:

$$W = 1.1K_3\frac{\left(g + 0.5a_v\right)F_{SC}}{8\lambda_s R_{eH}} \quad \text{cm}^3$$

$$A = \frac{5\left(g + 0.5a_v\right)F_{SC}}{0.9\tau_{eH}\sin\phi} \times 10^{-3} \quad \text{cm}^2$$

where: K_3— coefficient, defined in Table 2.25.5.1, to be taken as $2l_e/3$ for $n_2 > 10$;

l_e — effective span of stiffeners, in m, see 1.2.3, Section 2, Chapter 1 of this PART;

a_v— vertical acceleration, in m/s^2, calucated according to the formula defined in 1.5.2, Section 5, Chapter 1 of this PART;

g — acceleration due to gravity, g = 9.81 m/s^2;

F_{SC}—equivalent mass of steel coils, in kg, defined in 2.25.3;

R_{eH} — minimum yield stress of material, in N/mm^2;

λ_s ——permissible bending stress coefficient of stiffeners, taken 0.9;

τ_{eH} — shear yield stress of material, in N/mm^2, taken equal to:

$$\tau_{eH} = \frac{R_{eH}}{\sqrt{3}}$$

ϕ — angle between stiffener web and shell plating, in degree, to be taken at the middle of span of stiffener.

Coefficient K_3 **Table 2.25.5.1**

n_2	1	2	3	4	6	7	8	9	10
K_3	l_e	$l_e - \frac{l'^2}{l_e}$	$l_e - \frac{2l'^2}{3l_e}$	$l_e - \frac{5l'^2}{9l_e}$	$l_e - \frac{7l'^2}{15l_e}$	$l_e - \frac{4l'^2}{9l_e}$	$l_e - \frac{3l'^2}{7l_e}$	$l_e - \frac{5l'^2}{12l_e}$	$l_e - \frac{11l'^2}{27l_e}$

2.25.6 Stiffeners located on bilge hopper sloping plate or inner hull plate

2.25.6.1 The section modulus W and the net shear area A of single span stiffeners located on bilge hopper sloping plate and inner hull plate are not to be less than the values obtained from the following formulae:

$$W = 1.1K_3 \frac{a_{hopper} F'_{SC}}{8\lambda_s R_{eH}} \quad \text{cm}^3$$

$$A = \frac{5a_{hopper} F'_{SC}}{0.9\tau_{eH} \sin\phi} \times 10^{-3} \quad \text{cm}^2$$

where: K_3— coefficient, defined in Table 2.25.5.1, to be taken as 2l/3 for n_2 > 10;

l_e — effective span of stiffeners, in m, see 1.2.3, Section 2, Chapter 1 of this PART;

R_{eH} — minimum yield stress of material, in N/mm^2;

a_{hopper} — coefficient, defined in 2.25.4.1;

τ_{eH} — shear yield stress of material, in N/mm^2, see 2.25.5.1;

λ_s ——permissible bending stress coefficient of stiffeners, see 2.25.5.1;

F'_{SC}—equivalent mass of steel coils, in kg, defined in 2.25.4;

ϕ — angle, in degree, defined in 2.25.5.

Appendix 1 LOADING INSTRUMENTS

1 General Requirements

1.1 Application

1.1.1 This Appendix applies to loading instruments consisting of the onboard computer system as required by 2.2.8 of this Chapter.

1.1.2 This Appendix applies to onboard computers which are, as required by 1.9.1.3 of Chapter 1 of this PART, capable of providing intact stability information, and to onboard computers having stability software, as stated in 1.9.1.4 of that Chapter.

1.1.3 The loading instruments covered by this Appendix are passive systems with manual data entry and active systems in the off-line operation mode only, excluding any active system with sensors reading and entering the contents of tanks, etc., and any integrated system which controls or initiates actions based on the sensor-supplied inputs.

The definitions of passive, active and integrated systems are given in paragraph 2 of Appendix 2.

1.2 Class notations

1.2.1 The class notation for a loading instrument consists of any combination of Loading Computer and the letters S, I, G and D, with each of these four letters indicating that the loading instrument is capable of calculating and checking one of the following items:

S: Hull strength in various loading conditions.

I: Intact stability.

G: Stability for the carriage of grain in bulk.

D: Damage stability.

For example, the class notation of Loading Computer S, I, D shows that the ship is provided with a loading instrument capable of calculating and checking the hull strength, intact stability and damage stability in various loading conditions.

1.3 Inspections of loading instruments

1.3.1 Inspections of loading instruments include hardware inspection, software approval, actual installation inspection and inspection after construction. Steps of implementation for inspections of loading instruments are shown in Figure 1.3.1.

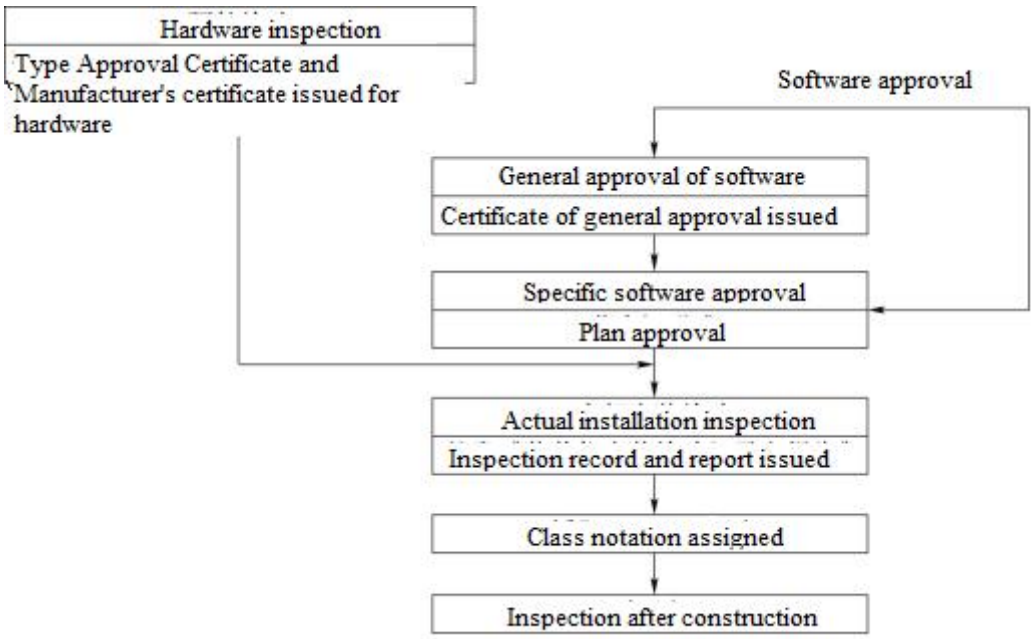

Figure 1.3.1 Steps of Implementation for Surveys of Loading Instruments

1.3.2 Software approval may be carried out by either one of the following two methods:

(1) On completion of general approval of software, software approval is carried out for a specific ship;

(2) Software approval is carried out directly to a specific ship.

1.3.3 Provision of loading instruments on board the ship may be made by either one of the following two methods:

(1) a single loading instrument to be provided on board the ship;

(2) two same loading instruments to be provided on board the ship, one for main use and the other as standby.

2 Hardware Inspections

2.1 General requirements

2.1.1 Loading instrument hardware inspections are to be carried out in accordance with the requirements for inspections of products in Chapter 3 of PART ONE of the Rules and this Section and, in general, consist of examination of plans and documents, type tests.

2.1.2 Hardware of loading instruments consists, in general, of computers and peripheral apparatus, where the printer is supplied as a separate unit from the computer, the type test of such a printer is not necessary.

2.1.3 Where two available loading instruments are installed onboard a ship, type approval certificate may be exempted, however, installation test is to be carried out.

2.2 Plans and documents

2.2.1 Where an application for hardware inspections is made, the following plans and documents should be submitted to CCS for approval:

(1) Technical specifications of hardware and peripheral apparatus;

(2) Fixing and installation of loading instruments;
(3) Type test program.

2.3 Type tests

2.3.1 Type tests are to be carried out by a verification and test organization authorized by CCS and, in general, with the presence of the CCS Surveyor.

2.3.2 Type test items

(1) Visual inspection;
(2) Performance;
(3) Electric power supply variations;
(4) Dry heat;
(5) Damp heat;
(6) Vibration;
(7) Inclination and rolling;
(8) Protection by enclosure;
(9) Low temperatures;
(10) Electromagnetic compatibility.

2.3.3 Where the loading instruments, of which hardware is installed in an air-conditioned room, are used only for the purpose of calculation, and no input of external signals or output of control signals is made, the items of type tests may be suitably reduced.

2.3.4 Where one main computer together with a standby one are provided onboard the ship, the hardware may not be subject to the type tests.

2.3.5 For the methods used in type tests, reference may be made to CCS Guidelines for Type Approval Test of Electric and Electronic Products or the relevant requirements of standards acceptable to CCS.

3 Functional Requirements for Software

3.1 General requirements

3.1.1 The functions of loading instruments are to cover at least calculating and indicating still water bending moment and shear force at the specified hull positions in any loading condition or light ship condition quickly and easily. Where applicable, the maximum permissible value of a still water torsional moment resulted from the non-uniform loading of cargoes is to be indicated.

3.1.2 Single point loading instruments (i.e. with only one check point on board the ship) are not acceptable to CCS.

3.1.3 Loading instruments are not to be substituted for the approved or confirmed final loading manual or stability information (hereinafter referred to as the final loading manual), and the results of the calculations are only applicable to the ship for which it has been approved.

3.1.4 For a specific ship, the requirements for overall strength are mandatory.Where the installed loading instruments have the function of stability calculations and are assigned an appropriate class notation, however, the stability calculation software is to be capable of calculations for all stability requirements (including intact stability, grain-carrying stability and damage stability),

either as mandatory or non-mandatory ones, applicable to the ship and is to contain relevant stability information, subject to the approval by CCS.

3.1.5 It is recommended that software be provided with an online help function, i.e. the software system may provide online help for input, output, calculation and printing.

3.1.6 The software is to be such that a common user can not alter the inputted data of the actual ship such as the geometrical characteristics, light ship weight, centre of gravity, capacity table, curve of allowable values.

3.1.7 The software is to be such that any user can not alter the inputted application programs.

3.1.8 The software is to, as far as possible, reduce significant or illogical input errors and alert the user to any input value exceeding the actual maximum capacity of a compartment or any negative value of the capacity.

3.1.9 The software is to be capable of clearly judging whether a loading condition complies with the relevant requirements, i.e. calculating for a certain loading condition. Where the calculation results exceed the permissible values, the user is to be alerted by distinct means such as prominent display, special markings or visible and audible alarms, screen display or printout.

3.1.10 The software is to be provided with passwords so that the computer will refuse to work and alert the user where any illegal password is input.

3.1.11 The software is to be at least capable of calculating the displacement and centre of gravity in any loading conditions and completing calculation and criteria of overall strength (and stability, if applicable) of the ship, displaying and printing out date and time of performing calculation and saving calculation results. All input data and calculation results displayed on the screen and printed out, including the fore and after draughts, are to be in definite and uniform measurement units and easily comparable with the approved final loading manual to avoid possible confusion and misunderstanding, with the identification marking and version number of the software being clearly indicated on each printed page.

3.1.12 The software interface is to be fully user-friendly and to alert the user to any operational error. Data loss or dead stop of the computer caused by the user's error is to be minimized.

3.2 Overall strength

3.2.1 The functional requirements for software in respect to overall strength are given in 2.2.8 of this Chapter.

3.3 Intact stability

3.3.1 The software is to use direct calculation to check intact stability and the following requirements are to be met:

(1) The software is to be capable of calculating and displaying the height of the centre of gravity and initial metacentric height of the ship and correcting free surface effects and comparing such values with the permissible values, where applicable. If any permissible value is exceeded, an alarm is to be automatically initiated.

(2) The software is to be at least capable of calculating and displaying *GZ* curves and correcting free surface effects.

(3) The software is to be capable of calculating the intact stability in any loading conditions and achieving the criteria for intact stability according to the relevant requirements. The method for achieving the criteria is to be in conformity with the final loading manual and any other method

used for this purpose is to be indicated in submissions and subject to agreement of CCS plan approval unit. The software is to be capable of automatically initiating an alarm in case of any permissible criterion being exceeded.

3.3.2 If damage stability is checked by the software according to the provisions of 3.5.2 of this Section, intact stability can be checked based on the same method.

3.4 Stability for carriage of grain in bulk

3.4.1 The software is to be in compliance with the relevant requirements in 3.3 of this Appendix.

3.4.2 The software is to be capable of inputting the permissible inclining moment curves.

3.4.3 The software is to be capable of calculating the stability for the carriage of grain in bulk and achieving the criteria for the stability according to the relevant requirements. The method for achieving the criteria is to be in conformity with the final loading manual. The software is at least to be able to calculate the inclining moment of actual shift of grain and the permissible inclining moment to which comparison is made. The software is to be capable of automatically initiating an alarm in case of any permissible value being exceeded.

3.5 Damage stability

3.5.1 If the software uses direct calculation to check damage stability, the following requirements are to be met:

(1) The software is to indicate whether the calculation is performed by means of loss of buoyancy or increase of weight, and the former is recommended.

(2) The software is to be capable of making corrections of free surface effects for *GZ* curves.

(3) The software is to be capable of allowing for corrections for liquid loss of damaged tanks.

(4) The software is to define the damaged compartment(s) and associated damage conditions in advance for selection by the crew in calculation, and be capable of calculating and displaying the *GZ* curves after damage.

(5) The software is to be capable of calculating the equilibrium position and stability in any damage condition, covering fore, after and mean draughts, trimming values, heeling angles, distance from equilibrium waterline to flooding openings, residual initial metacentric height, residual stability etc., and achieving the criteria for damage stability according to the relevant requirements. The method for achieving the criteria is to be in conformity with the final loading manual. The software is to be capable of automatically initiating an alarm in case of any permissible criterion being exceeded.

3.5.2 If damage stability is checked by the software on the basis of approved limit curves (the curve of permissible vertical position of the centre of gravity or the curve of permissible initial metacentric heights) or loading conditions, the following requirements are to be met:

(1) The software is to be capable of calculating and displaying displacement, the position of the centre of gravity, buoyancy and initial metacentric height of the ship in any loading condition and correcting free surface effects as required and comparing such values with the approved data.

(2) The software is to be capable of automatically initiating an alarm in case of any permissible criterion being exceeded (if limit curves are used) or any acceptable and safe tolerance being exceeded (compared with loading condition).

3.6 Additional requirements for bulk carriers, ore carriers and combination carriers

3.6.1 In addition to the above requirements, the loading instruments on board bulk carriers, ore carriers and combination carriers are to comply with the requirements of Section 7, Chapter 8 of this PART.

4 Software Approval

4.1 General requirements

4.1.1 Software approval consists of general approval and specific approval, covering:

(1) verification that the data used are consistent with the current condition of the ship;

(2) verification and approval of the test conditions;

(3) verification that the software is appropriate for the required type of ship and corresponding calculations.

4.2 Requirements for general approval of software

4.2.1 The general approval of software of loading instruments means approval of design and calculation programs of the software, i.e. approval of the design methods, calculation functions and principles and relevant documents for programing and usage of the said software through actual tests on representative ships selected according to the submitted scope of application.

4.2.2 The general approval of software of loading instruments may specifically include the following:

(1) Design methods, calculation functions and principles of the software are to be in conformity with the classification/statutory requirements and comply with the relevant requirements in section 3 of this Appendix.

(2) For ships of different types selected for tests, the calculation results for the typical loading conditions selected according 4.6 of this Appendix are, by comparison with those of the loading manual approved by CCS or CCS plan approval software, to comply with the accuracy requirements in 4.7 of this Appendix.

(3) User’s operation manual of loading instruments is to comply with the relevant requirements in 4.8 of this Appendix.

4.2.3 CCS will issue a Certificate of General Approval of Software of Loading Instruments to the software upon general approval by CCS.

4.2.4 The application and restrictions, e.g. applicable ship types and functional restrictions, are to be noted on the Certificate of General Approval of Software of Loading Instruments.

4.2.5 A Certificate of General Approval of Software of Loading Instruments remains valid for a period not exceeding 5 years. When the certificate expires and if the applicant confirms that no change has been made to the version of the said software, CCS will renew the Certificate of General Approval of Software of Loading Instruments. However, the plan approval unit responsible for the software approval is to carry out nonscheduled assessments of the software as necessary, e.g. in response to complaints from users.

4.2.6 Where the applicant has made any change to the software without re-approval by CCS, the Certificate of General Approval of Software of Loading Instruments issued by CCS is no longer valid.

4.2.7 Where the version of the loading instrument software, of which general approval is granted by CCS, is upgraded or changed, resubmission for approval is required. Submission of plans and documents which are the same as those for the approved version is unnecessary, but the applicant should indicate this in the application.

4.3 Steps of implementation for general approval of software

4.3.1 The general approval of software of loading instruments is to be carried out in accordance with the relevant CCS requirements for plan approval.

4.3.2 The applicant is to fill in an application for software approval of loading instruments. For the relevant contents of the application, refer to the relevant requirements of section 3 of this Appendix.

4.3.3 The test ships are to be so selected that all ship types and their functions as required in the application are covered. And the following are to be complied with:

(1) for the strength calculation software, the applicant is to select the calculation results for at least one test ship, which may be either the sample ship provided by CCS or the one determined by the applicant. Where the latter is selected, the prior agreement of the plan approval unit is necessary;

(2) for the stability calculation software, test ships are to be selected in accordance with 6.1 of Appendix 2 of this Chapter.

4.3.4 The applicant is to submit the following plans and documents to CCS plan approval unit. After examination and approval, one set of their copies is to be returned to the applicant, one set sent to the Headquarters of CCS and one set filed by the plan approval unit (where application for specific approval of the software is made for the test ship at the same time, an additional copy of the user's operation manual and that of the calculation and test report are required for CCS survey unit):

(1) Specification of the software system (for information), covering design method, calculation functions and principles, data structure as well as flowchart of the software, and explaining functional items as determined in the application and computational accuracy of the software such as methods used for numerical integration, interpolation, etc.

(2) User's operation manual of loading instruments (for information).

(3) Data of test ship(s) inputted in the software (for information), such as main dimensions, lightweight distribution and centre of gravity, Bonjean curves, hydrostatic data, tank capacity, permissible still water shear forces, permissible still water bending moments and, where applicable, correction factors of bulkhead shear forces and permissible still water torsional moments. Where the software has computation functions for intact stability, stability for the carriage of grain in bulk, damage stability, etc., corresponding data are also to be submitted for approval.

(4) Test report (for approval) of loading calculations for conditions to be selected according to the requirements in 4.6 of this Appendix with the agreement of the plan approval unit, covering the input data and all output results.

(5) General arrangement, lines, final loading manual of the test ship(s) and other additional plans or data required by CCS for information or use in check calculations.

(6) A set of installation discs, including the executing software and internal testing data.

4.3.5 On satisfactory completion of examination of the above-mentioned plans and documents, the Certificate of Software Approval of Loading Instruments may be issued.

4.4 Requirements for specific approval of software

4.4.1 The specific approval of software means, for the purpose of a specific ship, the approval of loading instrument's software installed on board, i.e. the approval of the design method, calculation functions and principles, input data, user's operation manual, full-scale test report and other documents.

4.4.2 The specific approval of software may specifically include the following:

(1) Design methods, calculation functions and principles of the software are to be in conformity with the classification requirements and comply with the relevant requirements in section 3 of this Appendix.

(2) All input data of the software are to be consistent with those of the actual ship, i.e. being taken from the finished documents approved or confirmed by CCS, and in particular the lightweight and centre of gravity are to be taken from the inclining test report. Where the software is capable of stability calculation, the input data are to comply with paragraph 6.2 of Appendix 2.

(3) The computation points along the ship's length and their number are to comply with CCS rules.

(4) The permissible still water bending moments, permissible still water shear forces, and where applicable, permissible still water torsional moments and correction factors of bulkhead shear forces at the computation points along the ship's length are to be consistent with those in the final loading manual.

(5) The calculation results for the typical loading conditions selected according to 4.6 of this Appendix are, by comparison with those of the final loading manual or CCS plan approval software, to comply with the accuracy requirements in 4.7 of this Appendix.

(6) User's operation manual of the loading instrument is to comply with the requirements in 4.8 of this Appendix.

4.4.3 For software with a Certificate of General Approval of Software of Loading Instruments and in respect to the applicable ship types and functions stated in the Certificate, where application is made for specific approval of the software, submission of design methods, calculation functions and principles of the software is unnecessary.

4.4.4 For software without a Certificate of General Approval of Software of Loading Instruments, the applicant may directly apply to CCS for specific approval of loading instrument software.

4.5 Steps of implementation for specific approval of software

4.5.1 The specific approval of software is to be carried out in accordance with the relevant CCS requirements.

4.5.2 For the relevant contents of the application, refer to the relevant requirements of section 3 of this Appendix.

4.5.3 The applicant is to submit the following plans and documents to CCS:

(1) For software without general approval by CCS, the applicable contents for the specific ship as required in (1), (2), (3), (4), (5) and (6) of 4.3.4 of this Appendix are to be submitted.

(2) For software with general approval by CCS, the applicable contents for the specific ship as required in (2), (3), (4), (5) and (6) of 4.3.4 of this Appendix and a copy of the Certificate of General Approval of Software of Loading Instruments are to be submitted.

4.6 Test conditions

4.6.1 Test conditions are to be selected from the final loading manual.

4.6.2 Test conditions are at least to contain loading conditions for the following:

(1) for minimum displacement, such as lightship condition or arrival condition with light ballast;

(2) for maximum still water bending moment, such as ballast or partially loaded conditions;

(3) for maximum displacement, such as fully loaded conditions;

(4) any condition resulting in extremely large still water shear force, such as ore loaded in alternate holds, etc.;

(5) where the software is capable of the stability calculation for carriage of grain in bulk, the test conditions are to include the one of a fully loaded hold with even filling at its ends, the one of a fully loaded hold with uneven filing at its ends and the one of a partly loaded hold;

(6) where the software is capable of both intact stability calculation and damage stability calculation, the necessary typical conditions are to comply with paragraph 6.2 of Appendix 2.

4.6.3 The test conditions are to contain the arrival and departure conditions and cover all loaded holds and all functions of the software as far as possible.

4.6.4 The approved test conditions are to be stored as input data in such a way that no user can alter them. A copy of the approved test conditions is to be available on board.

4.7 Permissible values and error control

4.7.1 All selected permissible values and the calculation points along the ship's length are to be taken from the finished documents approved by CCS.

4.7.2 The curves of still water shear forces and still water bending moments are to be consistent with the corresponding curve tendency in the final loading manual. The peak value of still water bending moment is normally to occur at the position where the still water shear force is zero.

4.7.3 The maximum values of still water shear force, still water bending moment and still water torsional moment and their calculated values at the calculation points along the ship's length are, as compared with the calculation results of the final loading manual, to have their errors controlled within the ranges given in Table 4.7.3.

Error Control **Table 4.7.3**

	Error (in comparison to approved value, %)
Still water shear force	$\leq \pm 5\%$
Still water bending moment	$\leq \pm 5\%$
Still water torsional moment	$\leq \pm 5\%$

4.7.4 The errors of the software in stability calculation are to comply with paragraph 5 of Appendix 2.

4.7.5 During examination, where the errors of the calculated values for individual calculation points of the loading instrument are significant as compared with the values of the final loading manual and no adequate evidence is available for wrong calculation of the loading instrument, check is to be made by using CCS plan approval software and the calculation results by this software are to be accepted as standard ones. Where any principled error is found in the final loading manual, the unit which has approved the manual is to be informed of this matter together with the recommendation that the existing loading manual be revised.

4.8 Operation manual

4.8.1 At least one copy of operation manual of loading instrument of the ship is to be kept on board.

4.8.2 The operation manual of loading instrument is to be written in a language used by the users on board, and the language is to be the same as that used for screen display, printout and the approved final loading manual kept on board. Where the language is not English, an English translation is to be available.

4.8.3 The operation manual is to be written in a clear and unambiguous manner. The use of flowcharts is recommended for illustrating operational processes.

4.8.4 The operation manual is to contain the following:

(1) particulars and version number of the software;

(2) a copy of the Certificate of General Approval of Software of Loading Instruments (where applicable);

(3) specification of hardware needed to run the software and guidance for software installation;

(4) software running steps shown in menus and dialogues, description of error messages and warnings likely to be encountered and unambiguous instructions for subsequent actions to be taken by the user in each case;

(5) lightweight and coordinates of centre of gravity;

(6) full deadweight description of each test condition for loading calculation;

(7) diagrams of the permissible still water shear forces and still water bending moments and where applicable, the permissible cargo torque;

(8) where applicable, shear force correction factors;

(9) operation procedure shown by calculation cases;

(10) input and output data, calculation results shown by screen display, with necessary explanatory text;

(11) explanation for function keys.

5 Actual Installation Inspections

5.1 General requirements

5.1.1 The Owner or the entrusting party is to submit application to CCS survey unit situated at the port of call of the ship.

5.1.2 The crew may master the operation and calculation of the loading instrument on board through learning or training. The installation inspection is to be carried out by the crew.

5.1.3 Actual installation inspection is to be carried out soon after the loading instrument has been installed on board the ship for verification of satisfactory operation and calculation and for check of strength and stability. Where by that time the final loading manual has not been approved, the installation inspection may be postponed until the manual is approved.

5.2 Inspections and tests

5.2.1 Where the loading instruments are provided as a main computer and a standby one on board a ship, installation inspections are to be carried out respectively and both computers are to be found satisfactory.

5.2.2 The installation inspections are to be carried out in the presence of CCS Surveyor. The

following items are to be included in the installation inspections:

(1) checking the certificate of hardware;

(2) checking that the user's operation manual and test report of loading calculation are kept on board the ship;

(3) examining the environment and position for installing the system: confirming that the position and method for installing the system are as required in the specification;

(4) system stability testing: the computer system is to be capable of working normally after a continuous running period of one hour;

(5) self-checking capability tests of hardware and peripheral apparatus: self-check tests to be carried out according to the specification for hardware and peripheral apparatus with self-check capability;

(6) transient power failure test: re-starting the system after a period of 30 s of transient power failure, and confirming that:

① it is still capable of working normally; and

② its programs and data are not lost;

(7) software security tests: where an illegal password is inputted (or in case of human maloperation), the system should refuse to work;

(8) software safety tests: a common user is not to be capable of changing the application program and the input ship's data such as geometrical characteristics, tank capacity table, curve of permissible values;

(9) system performance tests: the calculation results from the system operated by the crew of the ship based upon the loading conditions as stated in the approved test report of loading calculations are to be the same as those in the approved test report. Where the software is capable of stability calculation, tests are also to comply with paragraph 8 of Appendix 2.

5.2.3 The test report of loading calculations printed out by the loading instrument during installation inspection is to be confirmed and signed by the attending Surveyor. After satisfactory installation inspection, the sttending Surveyor will issue a report and CCS will assign an appropriate class notation to the loading instrument.

5.3 Inspections of existing loading instruments on board ships

5.3.1 For ships provided with loading instruments approved by other member Societies of IACS, the operation manual, test report of loading calculations approved and related certificates of loading instrument hardware and software issued by these Societies may be reviewed, and installation inspections are to be carried out in accordance with 5.2.2 of this Appendix.

5.3.2 For ships provided with loading instruments not complying with the relevant requirements of CCS or approved by a party which is not member of IACS, installation inspections are to be carried out once again.

5.3.3 For ships assigned with class notation "Loading Computer", the survey after construction is to be carried out in accordance with relevant requirements of 6.3.5 of Chapter 6, PART ONE of the Rules.

Appendix 2 IACS UR L5 COMPUTER SOFTWARE FOR ONBOARD STABILITY CALCULATIONS

(Rev.4, June 2020)

Application

This Unified Requirement is applicable to software which calculates the stability of actual loading conditions and which is installed on ships and on units subject to compliance with the 1966 Load Line Convention or the 1988 Protocol to the Load Line Convention, as amended, the IMO MODU Code and/or the 2008 IS Code.

The use of onboard computers for stability calculations is not a requirement of class.

Stability software installed onboard shall cover all mandatory class and statutory intact and damage stability requirements applicable to the ship. This UR, requires approval of software installed on onboard computers which is capable of performing stability calculations.

Active and passive systems are defined in paragraph 2. This UR covers passive systems and the off-line operation mode of active systems only.

The requirements in this UR apply to stability software on ships contracted for construction① on or after 1 July 2005②③④.

1 General

- The scope of a stability calculation software shall be in accordance with the stability information as approved by the Administration and shall at least include all information and perform all calculations or checks as necessary to ensure compliance with the applicable stability requirements.
- Approved stability software is not a substitute for the approved stability information, and is used as a supplement to the approved stability information to facilitate stability calculations.
- The input/output information shall be easily comparable with approved stability information so as to avoid confusion and possible misinterpretation by the operator relative to the approved stability information.
- An operation manual is to be provided for the onboard computer stability software.
- The language in which the stability information is displayed and printed out as well as the operation manual written shall be the same as used in the ship's approved stability information. The Society may require a translation into a language considered appropriate.
- The onboard computer software for stability calculations is to be ship specific and the results

---

① The "contracted for construction" date means the date on which the contract to build the vessel is signed between the prospective owner and the shipbuilder. For further details regarding the date of "contracted for construction", refer to IACS Procedural Requirement (PR) No.29.

② Changes introduced in Rev.2 of this UR are to be uniformly applied by IACS Societies on ships contracted for construction on or after 1 January 2007.

③ Changes introduced in Rev.3 of this UR are to be uniformly applied by IACS Societies on ships contracted for construction on or after 1 July 2018.

④ Changes introduced in Rev.4 of this UR are to be uniformly applied by IACS Societies on ships contracted for construction on or after 1 July 2021.

of the calculations are to be only applicable to the ship for which it has been approved.

− In case of modifications implying changes in the main data or internal arrangement of the ship, the specific approval of any original stability calculation software is no longer valid. The software is to be modified accordingly and reapproved.

2 Calculation Systems

A passive system requires manual data entry;
an active system replaces the manual entry with sensors reading and entering the contents of tanks, etc.; and
a third system, an integrated system, controls or initiates actions based on the sensor-supplied inputs and is not within the scope of this UR.

3 Types of Stability Software

Four types of calculations performed by stability software are acceptable depending upon a vessel's stability requirements:

Type 1

Software calculating intact stability only (for vessels not required to meet a damage stability criterion).

Type 2

Software calculating intact stability and checking damage stability on basis of a limit curve (e.g. for vessels applicable to SOLAS Part B-1 damage stability calculations, etc.) or checking all the stability requirements (intact and damage stability) on the basis of a limit curve.

Type 3

Software calculating intact stability and damage stability by direct application of preprogrammed damage cases based on the relevant Conventions or Codes for each loading condition (for some tankers, etc.).

Type 4

Software calculating damage stability associated with an actual loading condition and actual flooding case, using direct application of user defined damage, for the purpose of providing operational information for safe return to port (SRtP).

Damage stability of both Type 3 and Type 4 stability software shall be based on a hull form model, that is, directly calculated from a full three-dimensional geometric model.

4 Functional Requirements

4.1 General requirements for any type of stability software

4.1.1 The calculation program shall present relevant parameters of each loading condition in order to assist the Master in his judgement on whether the ship is loaded within the approval limits. The following parameters shall be presented for a given loading condition:

− deadweight data;
− lightship data;
− trim;
− draft at the draft marks and perpendiculars;
− summary of loading condition displacement, VCG, LCG and, if applicable, TCG;
− downflooding angle and corresponding downflooding opening (not applicable for Type 2

software which uses limit curve for checking all the stability requirements. However, if intact stability criteria are given in addition to the limit curve, downflooding angle and the corresponding downflooding opening shall be indicated);

− compliance with stability criteria: Listing of all calculated stability criteria, the limit values, the obtained values and the conclusions (criteria fulfilled or not fulfilled) (not applicable for Type 2 software which uses limit curve for checking all the stability requirements. However, if intact stability criteria are given in addition to the limit curve, the limit values, the obtained values and the conclusion shall be indicated).

4.1.2 A clear warning shall be given on screen and in hard copy printout if any of the loading limitations are not complied with.

Loading limitations shall include, but may not be limited to:

− Trim, draught, liquid densities, tank filling levels, initial heel;

− Use of limit KG/GM curves in conjunction with above for Type 2;

− Restrictions to the stowage height for timber where timber load lines are assigned.

4.1.3 Type 3 software is to include pre-defined relevant damage cases for both sides of the ship according to the applicable rules for automatic check of a given loading condition.

4.1.4 The date and time of a saved calculation shall be part of the screen display and hard copy printout.

4.1.5 Each hard copy printout shall contain identification of the calculation program including version number.

4.1.6 Units of measurement are to be clearly identified and used consistently within a loading calculation.

4.1.7 For Type 3 and Type 4 software, the system shall be pre-loaded with a detailed computer model of the complete hull, including appendages, all compartments, tanks and the relevant parts of the superstructure considered in the damage stability calculation, wind profile, down-flooding and up-flooding openings, cross-flooding arrangements, internal compartment connections and escape routes, as applicable and according to the type of stability software.

4.1.8 For Type 1 and Type 2 software, in case a full three dimensional model is used for stability calculations, the requirements of the computer model are to be as per paragraph 4.1.7 above to the extent as applicable and according to the type of stability software.

4.2 Further requirements for Type 4 stability software

4.2.1 The normal (Type 1, 2 and 3) and SRtP (Type 4) software need not be “totally separated”. Where the normal and SRtP software are not totally separated:

− the function of switching between normal software and Type 4 software shall be provided.

− the actual intact loading condition is to be the same for both functions (normal operation and SRtP); and

− the SRtP module needs only to be activated in case of an incident.

Approval of Type 4 (SRtP) software is for stability only.

4.2.2 In passenger ships which are subject to SRtP and have an onboard stability computer and shore-based support, such software need not be identical.

4.2.3 Each internal space shall be assigned its permeability as shown below, unless a more accurate permeability has been reflected in the approved stability information.

Space	Permeability

	Default	Full	Partially filled	Empty
Container Spaces	0.95	0.70	0.80	0.95
Dry Cargo spaces	0.95	0.70	0.80	0.95
Ro-Ro spaces	0.95	0.90	0.90	0.95
Cargo liquids	0.95	0.70	0.80	0.95
Intended for consumable liquids	0.95	0.95	0.95	0.95
Stores	0.95	0.60	(0.60)	0.95
Occupied by machinery	0.85			
Void spaces	0.95			
Occupied by accommodation	0.95			

4.2.4 The system shall be capable of accounting for applied moments such as wind, lifeboat launching, cargo shifts and passenger relocation.

4.2.5 The system shall account for the effect of wind by using the method in SOLAS regulation II-1/7-2.4.1.2 as the default, but allow for manual input of the wind speed/pressure if the on-scene pressure is significantly different (P = 120 N/m^2 equates to Beaufort 6; approximately 13.8 m/s or 27 knots).

4.2.6 The system shall be capable of assessing the impact of open main watertight doors on stability (e.g. for each damage case provided for verification, additional damage stability calculation shall be done and presented, taking into account any watertight door located within the damaged compartment(s)).

4.2.7 The system shall utilize the latest approved lightship weight and centre of gravity information.

4.2.8 The output of the software is to be such that it provides the master with sufficient clear unambiguous information to enable quick and accurate assessment of the stability of the vessel for any actual damage, the impact of flooding on the means of escape and the controls of devices necessary for managing and/or controlling the stability of the ship.

When the actual loading condition is input in the SRtP software, the following output (intact stability) shall be available:

− deadweight data;
− lightship data;
− trim;
− heel;
− draft at the draft marks and perpendiculars;
− summary of loading condition displacement, VCG, LCG and, if applicable, TCG;
− downflooding angle and corresponding downflooding opening;
− free surfaces;
− GM value;
− GZ values relevant to an adequate range of heeling (not less than 60°) available indicatively at the following intervals: 0 5 10 15 20 25 30 40 50 60 deg;
− compliance with relevant intact stability criteria (i.e. 2008 IS Code): listing of all calculated intact stability criteria, the limiting values, the obtained values and the evaluation (criteria fulfilled or not fulfilled);
− GM/KG limiting curve according to SOLAS, Ch II-1, Regulation 5-1.

When the actual loading condition is associated to the actual damage case(s) due to the casualty, the following output (damage stability) shall be available:

− trim;
− heel;
− draft at the draft marks and perpendiculars;
− progressive flooding angle and corresponding progressive flooding openings;
− GM value;
− GZ values relevant to an adequate range of heeling (not less than 60°) available indicatively at the following intervals: 0 5 10 15 20 25 30 40 50 60 deg;
− compliance with stability criteria: listing of all calculated stability criteria, the limit values, the obtained values and the conclusions (criteria fulfilled or not fulfilled);
− the survivability criteria for Type 4 software (SRtP) are left to the discretion of the Administration;
− relevant flooding points (unprotected or weathertight) with the distance from the damage waterline to each point;
− list of all flooded compartments with the permeability considered;
− amount of water in each flooded compartment;
− escape route immersion angles;
− a profile view, deck views and cross-sections of the ship indicating the flooded waterplane and the damaged compartments.

4.2.9 For ro-ro passenger ships there shall be algorithms in the software for estimating the effect of water accumulation on deck (WOD) (e.g. 1. In addition to the predefined significant wave height taken from the approved stability document, there shall be possibility for the crew to input manually the significant wave height of the ship navigation area in the system, 2. In addition to the predefined significant wave height taken from the approved stability document, calculations with two additional significant wave heights shall be submitted for checking the correctness of the algorithms in the software for estimating the effect of WOD). *

* This paragraph applies to Ro-Ro Passenger ships subject to the Stockholm Agreement (IMO Circular Letter No. 1891)

5 Acceptable Tolerances

Depending on the type and scope of programs, the acceptable tolerances are to be determined differently, according to 5.1 or 5.2. Deviation from these tolerances shall not be accepted unless the Society considers that there is a satisfactory explanation for the difference and that there will be no adverse effect on the safety of the ship.

Examples of pre-programmed input data include the following:

Hydrostatic data: Displacement, LCB, LCF, VCB, KM_t and MCT versus draught.

Stability data: KN or MS values at appropriate heel/trim angles versus displacement, stability limits.

Compartment data: Volume, LCG, VCG, TCG and FSM/Grain heeling moments vs level of the compartment's contents.

Examples of output data include the following:

Hydrostatic data: Displacement, LCB, LCF, VCB, KM_t and MCT versus draught as well as actual draughts, trim.

Stability data: FSC (free surface correction), GZ-values, KG, GM, KG/GM limits, allowable grain heeling moments, derived stability criteria, e.g. areas under the GZ curve, weather criteria.

Compartment data: Calculated Volume, LCG, VCG, TCG and FSM/Grain heeling moments vs level of the compartment's contents.

The computational accuracy of the calculation program results shall be within the acceptable tolerances, specified in 5.1 or 5.2, of the results using an independent program or the approved stability information with identical input.

5.1 Programs which use only pre-programmed data from the approved stability information as the basis for stability calculations, shall have zero tolerances for the printouts of input data.

Output data tolerances are to be close to zero, however, small differences associated with calculation rounding or abridged input data are acceptable.

Additionally differences associated with the use of hydrostatic and stability data for trims that differ from those in the approved stability information are acceptable, subject to review by the individual Society.

5.2 Programs which use hull form models as their basis for stability calculations, shall have tolerances for the printouts of basic calculated data established against either data from the approved stability information or data obtained using the approval authority's model. Acceptable tolerances shall be in accordance with Table 1.

Table 1

Hull Form Dependent	
Displacement	+/- 2%
Longitudinal center of buoyancy, from *AP*	+/- 1%/50 cm
Vertical center of bouyancy	+/- 1%/5 cm
Transverse center of bouyancy	+/- 0.5% of *B*/ 5 cm
Longitudinal center of flotation, from *AP*	+/- 1%/50 cm
Moment to trim 1 cm	+/- 2%
Transverse metacentric height	+/- 1%/5 cm
Longitudinal metacentric height	+/- 1%/50 cm
Cross curves of stability	+/- 5 cm
Compartment dependent	
Volume or deadweight	+/- 2%
Longitudinal center of gravity, from *AP*	+/- 1%/50 cm
Vertical centre of gravity	+/- 1%/5 cm
Transverse center of gravity	+/- 0.5% of *B*/5 cm
Free surface moment	+/- 2%
Shifting moment	+/- 5%
Level of contents	+/- 2%
Trim and stability	
Draughts (forward, aft, mean)	+/- 1%/5 cm
GM_t (both solid and corrected for free surfaces)	+/- 1%/5 cm
GZ values	+/- 5% /5 cm
Downflooding angle	+/- 2°
Equilibrium angles	+/- 1°
Distance from *WL* to unprotected and weathertight openings, or other relevant point, if applicable	+/- 5%/5 cm
Areas under righting arm curve	+/- 5% / 0.0012 m · rad

Notes:

1. Deviation in % = [(base value − applicant's value)/base value] × 100

where the "base value" may be from the approved stability information or the society's computer model.

2. When applying the tolerances in Table 1 having two values, the allowable tolerance is the greater of the two values.

3. Where differences in calculation methodology exist between the programs used in the comparison, this may be a basis for accepting deviations greater than that specified in Table 1 provided a software examination is carried out in sufficient detail to clearly document that such differences are technically justifiable.

4. Deviation from these tolerances shall not be accepted unless the Society considers that there is a satisfactory explanation for the difference and that it is clearly evident from the Society's stability calculations that the deviation does not impact compliance with the required stability criteria for the ship under consideration.

6 Approval Procedure

Conditions of approval of the onboard software for stability calculations

The onboard software used for stability calculations is subject to approval, which is to include:

- verification of type approval, if any;
- verification that the data used are consistent with the current condition of the ship (refer to paragraph 6.2);
- verification and approval of the test conditions;
- verification that the software is appropriate for the type of ship and stability calculations required;
- verification of functional requirements under paragraph 4.1.2.

The satisfactory operation of the software with the onboard computer(s) for stability calculations is to be verified by testing upon installation (refer to paragraph 8). A copy of the approved test conditions and the operation manual for the computer/software are to be available on board.

6.1 General Approval (optional)

Upon application to the Society for general approval of the calculation program, the Society may provide the applicant with test data consisting of two or more design data sets, each of which is to include a ship's hull form data, compartmentation data, lightship characteristics and deadweight data, in sufficient detail to accurately define the ship and its loading condition. Acceptable hull form and compartmentation data may be in the form of surface coordinates for modeling the hull form and compartment boundaries, e.g: a table of offsets, or in the form of pre-calculated tabular data, e.g: hydrostatic tables, capacity tables, etc., depending upon the form of data used by the software being submitted for approval. Alternatively, the general approval may be given based on at least two test ships agreed upon between the Society and the applicant.

In general, the software is to be tested for two types of ships for which approval is requested, with at least one design data set for each of the two types. Where approval is requested for only one type of ship, a minimum of two data sets for different hull forms of that type of ship are required to be tested. For calculation software which is based on the input of hull form data, design data sets shall be provided for three types of ships for which the software is to be approved, or a minimum of three data sets for different hull forms if approval is requested for only one type of ship. Representative ship types which require different design data sets due to their hull forms, typical arrangements, and nature of cargo include: tanker, bulk carrier, container ship, and other dry cargo and passenger ships. The test data sets shall be used by the applicant to run the calculation program for the test ships. The results obtained (together with the hydrostatic data and cross-curve data developed by the program, if appropriate) shall be submitted to the Society for the assessment of the program's computational accuracy. The Society shall perform parallel calculations using the same data sets and a comparison of these results will be made against the applicant's submitted program's results.

6.2 Specific Approval

- The Society shall verify the accuracy of the computational results and actual ship data used by the calculation program for the particular ship on which the program will be installed.
- Upon application to the Society for data verification, the Society and the applicant shall agree on a minimum of four loading conditions, taken from the ship's approved stability information, which are to be used as the test conditions. For ships carrying liquids in bulk, at least one of the conditions shall include partially filled tanks. For ships carrying grain in bulk, one of the grain loading conditions shall include a partially filled grain compartment. Within the test conditions each compartment shall be loaded at least once. The test conditions normally are to cover the range of load draughts from the deepest envisaged loaded condition to the light

ballast condition and shall include at least one departure and one arrival condition.

For Type 4 stability software for SRtP, the Society shall examine at least three damage cases, each of them associated with at least three loading conditions taken from the ship's approved stability information. Output of the software is to be compared with results of corresponding load / damage case in the approved damage stability booklet or an alternative independent software source.

- The Society is to verify that the following data, submitted by the applicant, is consistent with arrangements and most recently approved lightship characteristics of the ship according to current plans and documentation on file with the Society, subject to possible further verification on board:
  - Identification of the calculation program including version number;
  - Main dimensions, hydrostatic particulars and, if applicable, the ship profile;
  - The position of the forward and after perpendiculars, and if appropriate, the calculation method to derive the forward and after draughts at the actual position of the ship's draught marks;
  - Ship lightweight and centre of gravity derived from the most recently approved inclining experiment or light weight check;
  - Lines plan, offset tables or other suitable presentation of hull form data if necessary for the Society to model the ship;
  - Compartment definitions, including frame spacing, and centres of volume, together with capacity tables (sounding/ullage tables), free surface corrections, if appropriate;
  - Cargo and consumables distribution for each loading condition.

Verification by the Society does not absolve the applicant and shipowner of responsibility for ensuring that the information programmed into the onboard computer software is consistent with the current condition of the ship.

7 Operation Manual

A simple and straightforward operation manual is to be provided, containing descriptions and instructions, as appropriate, for at least the following:

- installation;
- function keys;
- menu displays;
- input and output data;
- required minimum hardware to operate the software;
- use of the test loading conditions;
- computer-guided dialogue steps;
- list of warnings.

8 Installation Testing

To ensure correct working of the computer after the final or updated software has been installed, it is the responsibility of the ship's Master to have test calculations carried out according to the following pattern in the presence of a Society surveyor:

From the approved test conditions at least one load case (other than light ship) shall be calculated.

Note: Actual loading condition results are not suitable for checking the correct working of the computer.

Normally, the test conditions are permanently stored in the computer.

Steps to be performed:

- Retrieve the test load case and start a calculation run; compare the stability results with those in the documentation.
- Change several items of deadweight (tank weights and the cargo weight) sufficiently to change the draught or displacement by at least 10%. The results are to be reviewed to ensure that they differ in a logical way from those of the approved test condition.
- Revise the above modified load condition to restore the initial test condition and compare the results. Confirm that the relevant input and output data of the approved test condition have been replicated.
- Alternatively, one or more test conditions shall be selected and the test calculation performed by entering all deadweight data for each selected test condition into the program as if it were a proposed loading. The results shall be verified as identical to the results in the approved copy of the test conditions.

9 Periodical Testing

It is the responsibility of the ship's Master to check the accuracy of the onboard computer for stability calculations at each Annual Survey by applying at least one approved test condition. If a Society surveyor is not present for the computer check, a copy of the test condition results obtained by the computer check is to be retained on board as documentation of satisfactory testing for the surveyor's verification.

At each Special Survey this checking for all approved test loading conditions is to be done in presence of the surveyor.

The testing procedure shall be carried out in accordance with paragraph 8.

10 Other Requirements

Protection against unintentional or unauthorised modification of programs and data shall be provided.

The program shall monitor operation and activate an alarm when the program is incorrectly or abnormally used.

The program and any data stored in the system shall be protected from corruption by loss of power.

Error messages with regard to limitations such as filling a compartment beyond capacity, or exceeding the assigned load line, etc., shall be included.

Appendix 3 Guidelines for UR S11.2.1.3 for ballast loading conditions of cargo vessels involving partially filled ballast tanks

1 General guidance note regarding the use of UR S11.2.1.3

1.1 This document is intended for guidance and interpretation of UR S11.2.1.3 “Partially filled ballast tanks in ballast loading conditions”.

1.2 Case A and B are generally applicable for ballast loading conditions for any cargo vessel which might have one Ballast Water (BW) Tank (or one pair of BW Tanks) partially filled.

1.3 Case C is showing the conditions necessary for checking longitudinal strength for a conventional ore carrier with two pairs of large wing water ballast tanks partly filled during the ballast voyage.

1.4 Where applicable, similar considerations are to be given to other cargo vessels covered by UR S11 where ballast loading conditions involving partially filled ballast tanks may cause concerns for the longitudinal strength of the vessels.

1.5 This Appendix does not apply to CSR Bulk Carriers and Oil Tankers or to container ships to which UR S11A is applicable.

1.6 In the Figures, the conditions only intended for strength verification (not operational) are marked with a star (*), full tanks are marked with “Full”, empty tanks are marked with “Empty”, and consumables are marked with “cons.” .

2 Case A and B

2.1 Case A

Fig. 1 shows Case A, with a cargo vessel where partial filling of BW Tank no. 6 (P/S) is permitted and may take place at any time during the ballast voyage. Intermediate condition(s) should be specified as shown in the Figure, however filling/partial filling of BW Tank no. 6 (P/S) may be done at any step to keep acceptable trim and propeller immersion during the ballast voyage.

To obtain full operational flexibility regarding the filling level of BW Tank no. 6 (P/S), loading conditions A2 (full at departure)* and A8 (empty at arrival)* shall be added for strength verification. Additional conditions (full and empty BW Tank no. 6 (P/S)) related to the intermediate conditions A3-A6 are not necessary as A2* and A8* will be the most critical one.

2.2 Case B

Fig. 2 shows Case B, with a cargo vessel where partial filling of BW Tank no. 6 (P/S) to a given level (f6-int%) will be done after a specified % consumables is reached, see conditions B2 and B3. Before this % consumables (shown as 50% in this Figure) is reached, BW Tank no. 6 (P/S) shall be kept empty. When reaching a given level of consumables (shown as 20% in Figure 2), BW Tank no. 6 (P/S) shall be kept full, see conditions B5 and B6. Two additional intermediate conditions (B4* and B7*) shall be added for longitudinal strength verification.

In order to categorize a vessel according to Case B, clear operational guidance for partial filling of ballast tanks, in association with the consumption level as shown in Figure 2, is to be given in the loading manual. If such operational guidance is not given, Case A is to be applied.

Case A has no limitation of consumables, whereas Case B has limitation of consumables.

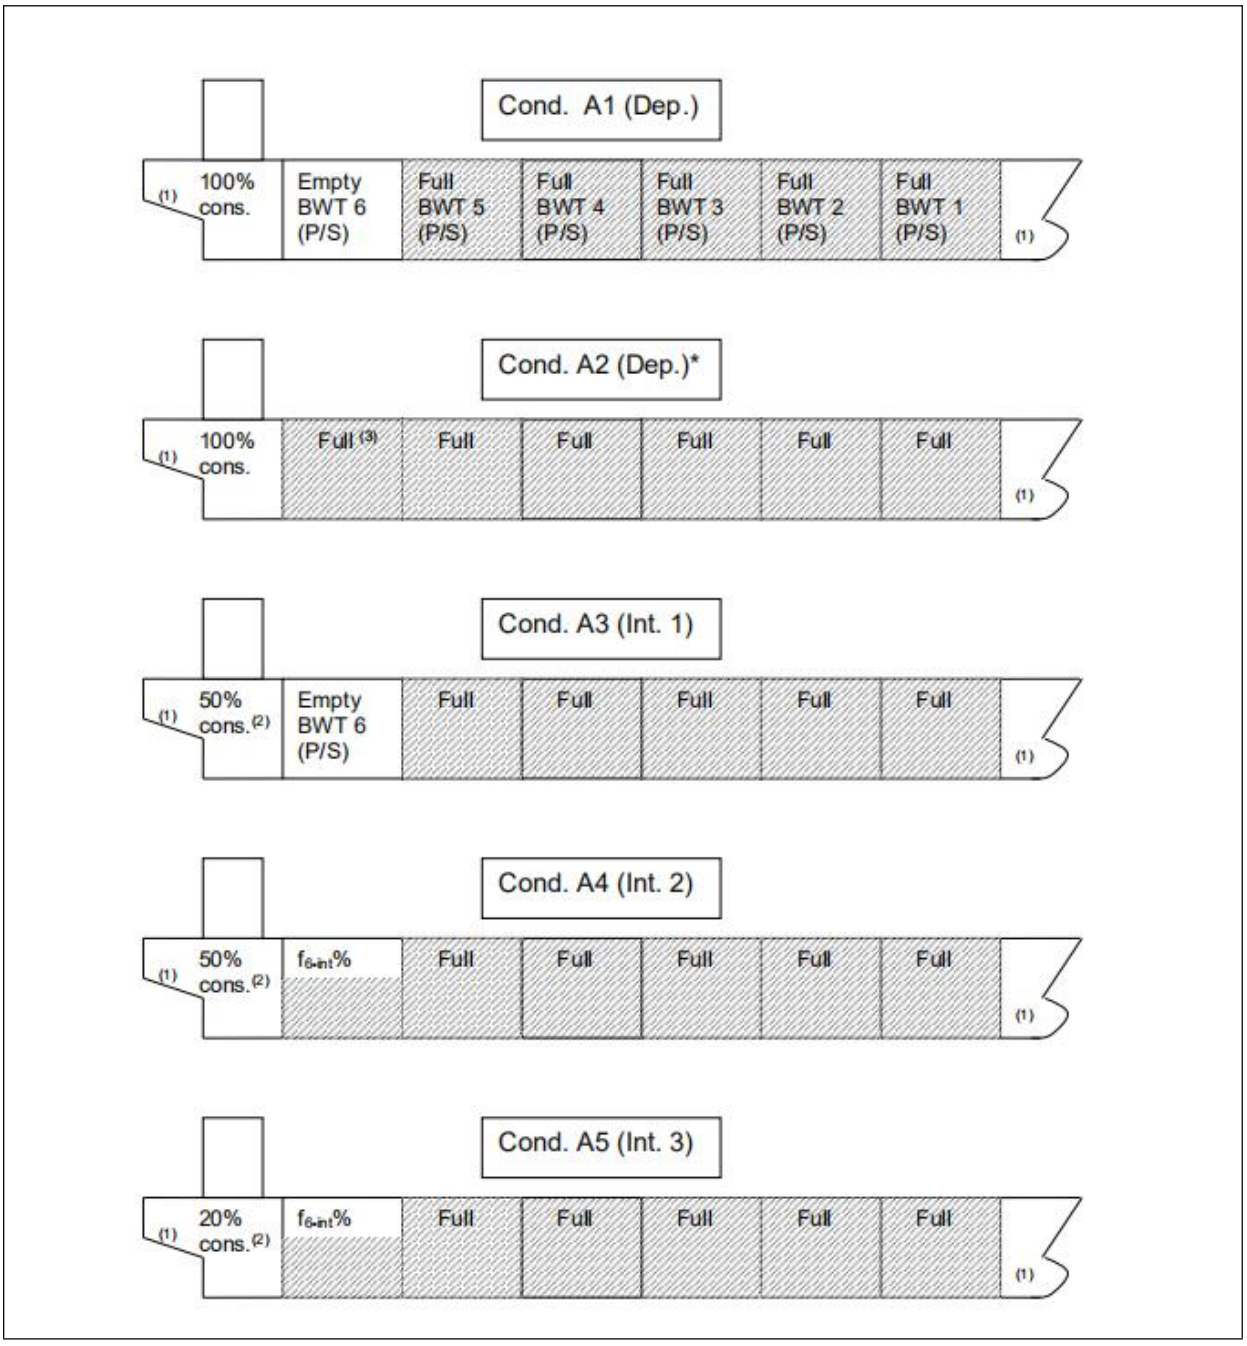

Figure 1 Case A, Partial filling of ballast tank no. 6 (P/S) is permitted at any stage during voyage. The intermediate conditions are specified, however other partial filling of BW Tank no. 6 (P/S) may be applied to keep acceptable trim and propeller immersion during the ballast voyage. Conditions only intended for strength verification (not operational) are marked: *

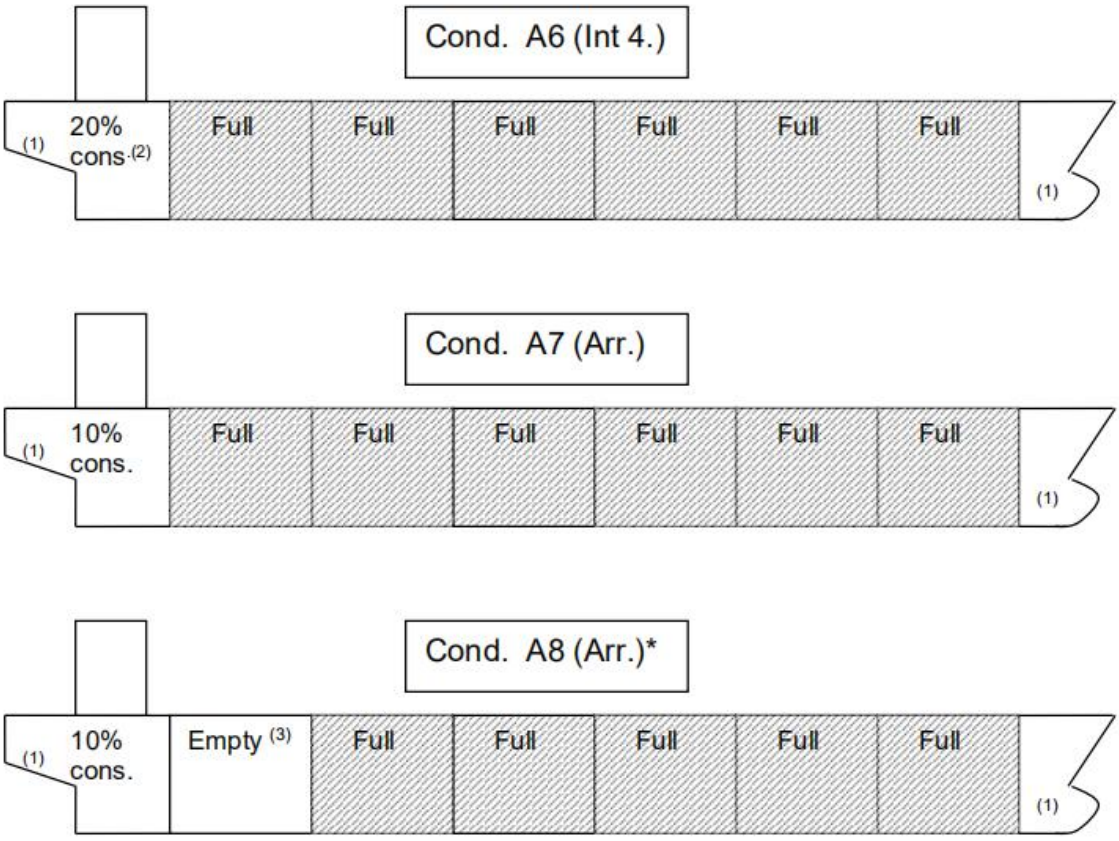

Notes

(1) For peak tanks intended to be partially filled, all combinations of full or partially filled at intended level for those tanks are to be investigated.

(2) The intermediate condition(s) to be specified incl. % consumables.

(3) For bulk carriers carrying ore and with large wing water ballast tanks full/empty may be replaced with maximum/minimum filling levels according to trim limitations given in S11.2.1.3.

Figure 1 (Continued)

Case A, Partial filling of ballast tank no. 6 (P/S) is permitted at any stage during voyage. The intermediate condition is specified, however other partial filling of BW Tank no. 6 (P/S) may be applied to keep acceptable trim and propeller immersion during the ballast voyage. Conditions only intended for strength verification (not operational) are marked: *

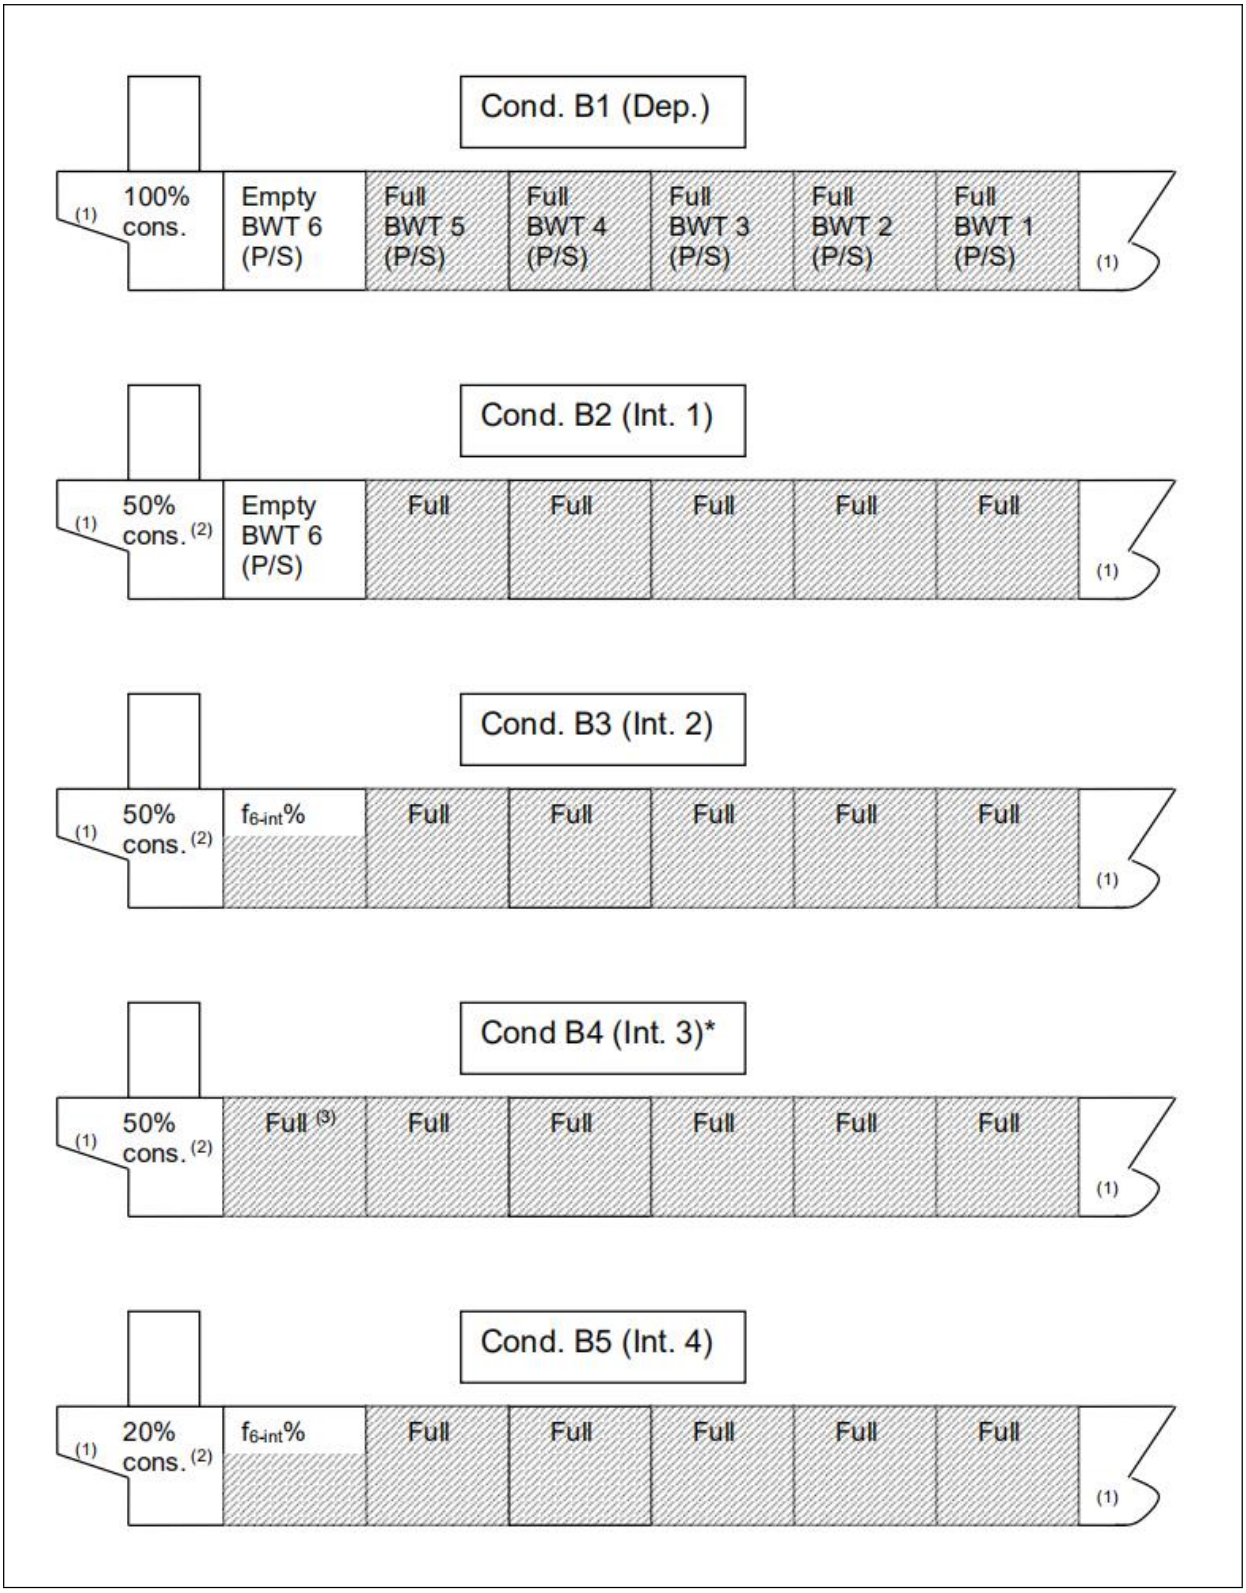

Figure 2 Case B, Partial filling of BW Tank no. 6 (P/S) only allowed during intermediate conditions, in this example between 50-20% consumables. Conditions only intended for strength verification (not operational) are marked: *

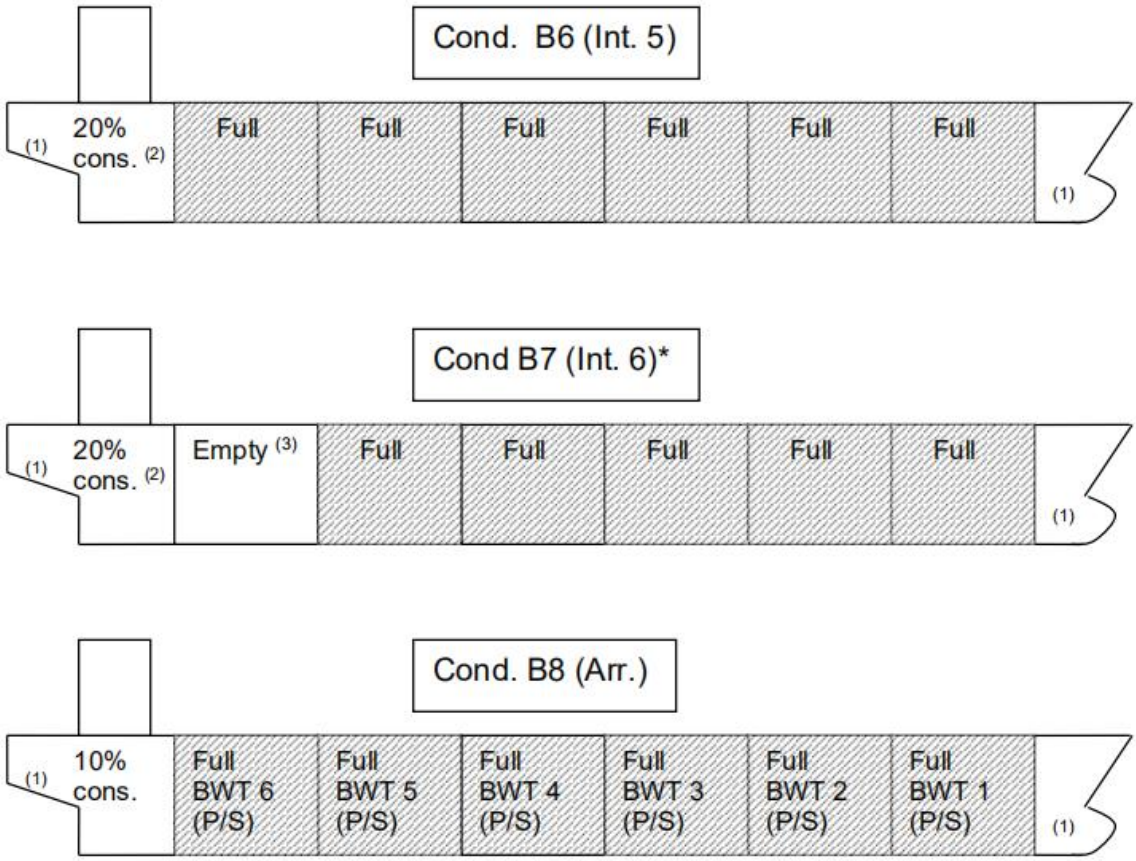


Notes

(1) For peak tanks intended to be partially filled, all combinations of full or partially filled at intended level for those tanks are to be investigated.

(2) The intermediate condition(s) to be specified incl. % consumables.

(3) For bulk carriers carrying ore and with large wing water ballast tanks full/empty may be replaced with maximum/minimum filling levels according to trim limitations given in S11.2.1.3.

Figure 2 (Continued)

Case B, Partial filling of BW Tank no. 6 (P/S) only allowed during intermediate conditions, in this example between 50-20% consumables. Conditions only intended for strength verification (not operational) are marked: *

3 Case C – Conventional (with usual arrangement of WBT) ore carrier with two pairs of partially filled ballast water tanks

Fig. 3(a) show the operational loading conditions, departure condition (C1), four intermediate conditions (C2-C5) and arrival condition (C6), for a conventional (with usual arrangement of WBT) ore carrier with partial filling of both BW tank no.1 (P/S) and 7 (P/S) during voyage.

Filling level in partially filled BW tanks nos.1 (P/S) and 7 (P/S) for the operational conditions during ballast voyage is given in Table 1.

Table 1

Loading condition	Consumables	Filling level, WBT 1(P/S)	Filling level, WBT 7(P/S)
C1–Departure	100%	f_{1dep}%	f_{7dep}%
C2–Intermediate 1	50%(1)	f_{1dep}%	f_{7dep}%
C3–Intermediate 2	50%(1)	f_{1int}%	f_{7int}%
C4–Intermediate 3	20%(1)	f_{1int}%	f_{7int}%
C5–Intermediate 4	20%(1)	f_{1arr}%	f_{7arr}%
C6–Arrival	10%	f_{1arr}%	f_{7arr}%

Note: (1) % consumables to be specified, indicated to 50% and 20 %.

Fig. 3(b) and Fig. 3(c) show the additional twelve loading conditions (C1-1 ~ C1-12) which shall be added for longitudinal strength verification of the departure condition (C1).

Fig. 3(d) and Fig. 3(i) show the additional 32 loading conditions (C2-1 ~ C2-12, C3-1 ~ C3-4, C4-1 ~ C4-12 and C5-1 ~ C5-4) which shall be added for longitudinal strength verification of the intermediate conditions (C2 ~ C5).

Fig. 3(j) and Fig. 3(k) show the additional twelve loading conditions (C6-1 ~ C6-12) which shall be added for longitudinal strength verification of the arrival condition (C6).

For the additional loading conditions, the maximum and the minimum filling level of BW tank are according to trim and propeller immersion limitations given in S11.2.1.3:

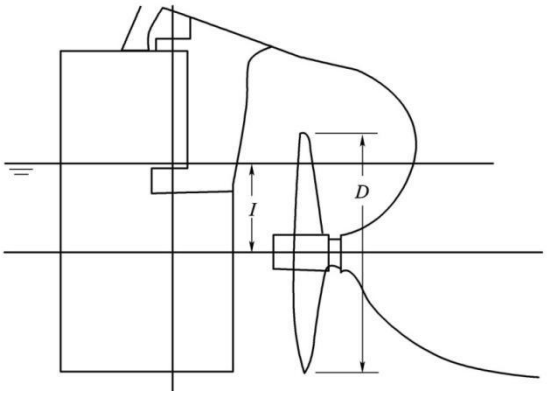
However, for conventional ore carriers with large wing water ballast tanks in cargo area, where empty or full ballast water filling levels of one or maximum two pairs of these tanks lead to the ship's trim exceeding one of the following conditions, it is sufficient to demonstrate compliance with maximum, minimum and intended partial filling levels of these one or maximum two pairs of ballast tanks such that the ship's condition does not exceed any of these trim limits. Filling levels of all other wing ballast tanks are to be considered between empty and full. The trim conditions mentioned above are:

- trim by stern of 3% of the ship's length, or
- trim by bow of 1.5% of ship's length, or
- any trim that cannot maintain propeller immersion (I/D) not less than 25%, where;

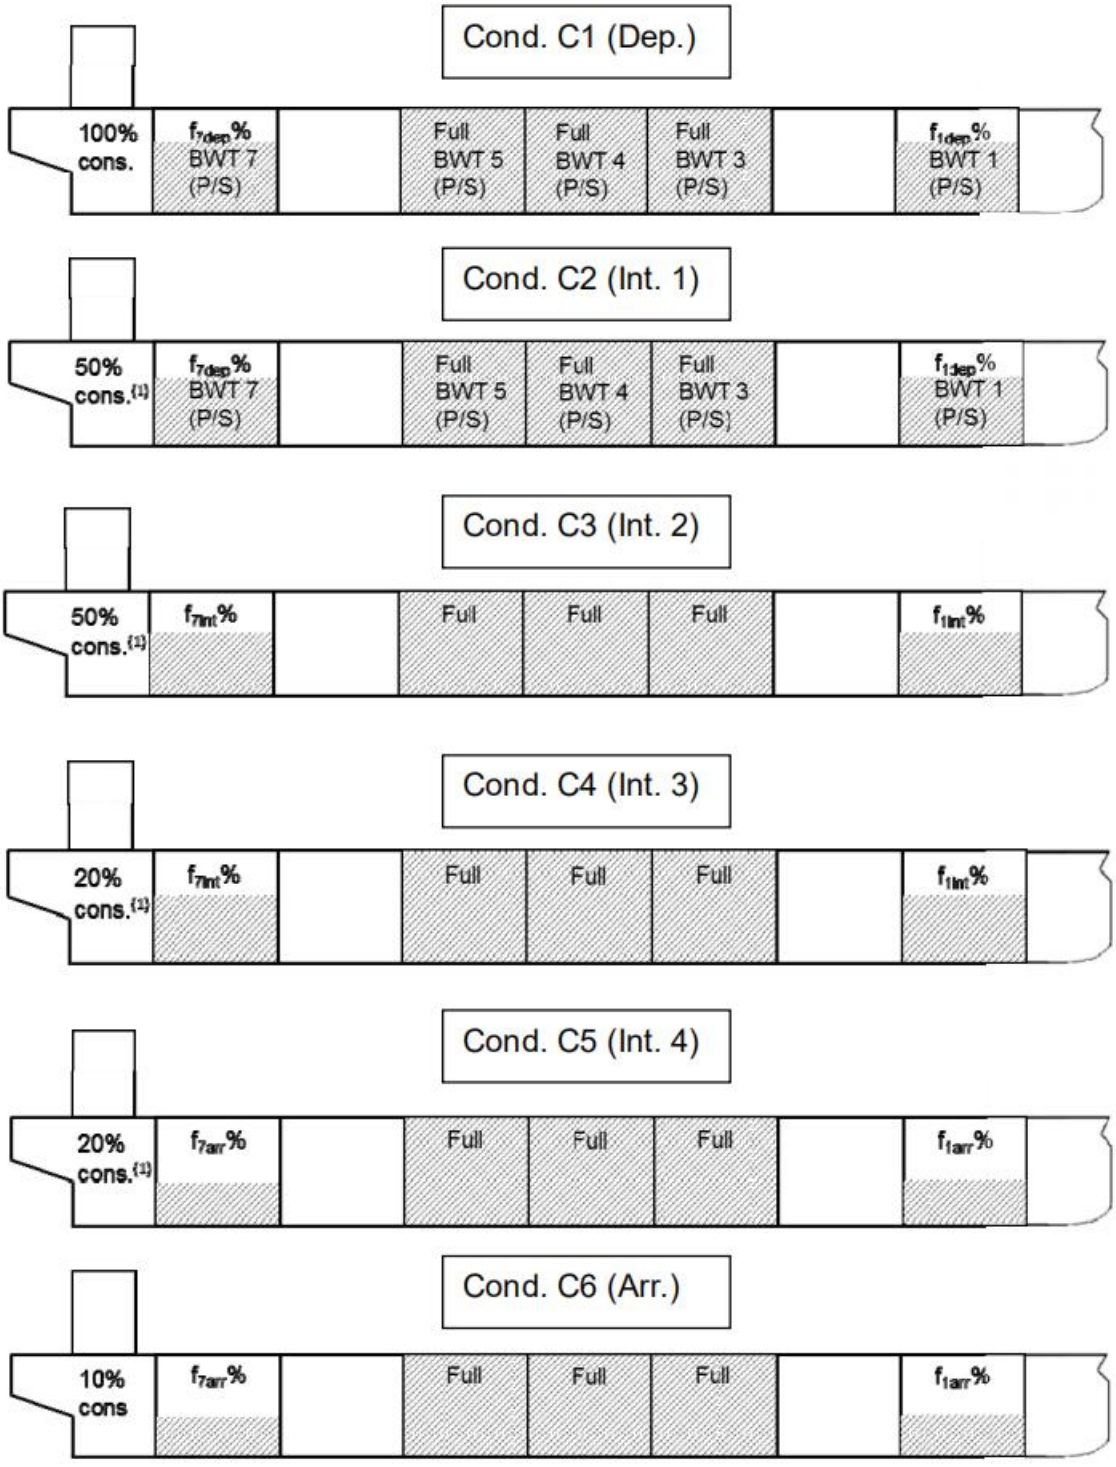
I = the distance from propeller centerline to the waterline

D = propeller diameter

(see the following figure)



I
D



Notes

(1) The intermediate condition(s) to be specified incl. % consumables.

(2) Figures 3(b)-3(k): Maximum and minimum filling level of BW tank according to trim and propeller immersion limitations given in S11.2.1.3.

Appendix 4 SLAMMING STRENGTH ASSESSMENT OF BOW BOTTOM STRUCTURES

1 General

1.1 General provisions

1.1.1 This Appendix applies to strength assessment of bow bottom structures against slamming for mono-hull ships.

1.1.2 The strength assessment against bottom slamming in this Appendix is based on Ochi-Mottor theory to predict the extreme value of slamming pressures and anti-plastic failure method to evaluate the slamming strength of shell plating, longitudinals and bottom grillage.

1.1.3 The longitudinal extent for the strength assessment of bow bottom slamming is to be consistent with that specified in 2.15.3 of Chapter 2 of this PART.

1.1.4 Where direct calculation is adopted, the relative motion results required by the procedure to calculate the slamming pressures are to be given by solving three-dimensional linear sea-keeping program.

2 Slamming Pressure

2.1 Calculation of slamming pressures

2.1.1 The slamming pressures P_B, in kPa, at each section is to be obtained from the following formula:

$$P_B = eP_S$$

where: e — correction coefficient, see 2.15.3.5 of this Chapter;

P_S — extreme value of slamming pressures, calculated in way of each transverse section when e =1 and the maximum value is taken, in kPa, to be obtained by the following formula:

$$P_S = \frac{1}{2}\rho k_1 C_{ps}\left\{V_0^2 - 2E_v \ln\left[1-(1-\alpha)^{1/n}\right]\right\}$$

where: ρ — density of seawater, in t/m^3, taken as 1.025;

k_1 — slamming coefficient, obtained according to Table 2.1.1, the intermediate value may be obtained from interpolation:

Slamming Coefficient k_1 **Table 2.1.1**

b_1 / d_1	1.0	2.0	4.0	6.0	8.0	10.0	12.0	14.0	16.0	18.0

For containerships, passenger ships and vehicle carriers	4.0	9.5	20.0	26.0	29.5	32.0	33.0	34.2	35.3	36.2
For other types of ships	4.0	9.5	20.0	26.0	28.5	29.6	30.0	29.6	28.8	28.0

d_1 — d/10, in m, where d is the draught;

b_1 — half breadth of the waterline for the transverse section concerned under draught d_1, in m;

C_{ps} — coefficient, taken as 0.44;

V_0 — critical slamming speed, in m/s, obtained from the following formulae:

$$V_0=\begin{cases}0.0925\sqrt{L}, & \text{for container ship, passenger ship and vehicle carrier}\\ 0.07\sqrt{L}, & \text{for other ship}\end{cases}$$

E_v — variance of vertical relative velocities for the hull and wave surface of transverse section concerned, determined according to 2.1.2 of this Appendix;

α — assurance rate, taken as 0.01;

n — number of impacts, replaced by the mean number of impacts N within t_n, obtained from the following formula:

$$N=3600\frac{t_n}{2\pi}\sqrt{\frac{E_v}{E_r}}\exp\left\{-\left(\frac{T_f^2}{E_r}+\frac{V_0^2}{E_v}\right)\right\}$$

where: t_n — the calculated navigation time, in h, obtained according to Table 2.2.4;

E_r — variance of vertical relative motions for the hull and wave surface of transverse section concerned, determined according to 2.1.2 of this Appendix;

T_f — draught of transverse section concerned in assessment condition, in m.

2.1.2 Variance of vertical relative motions for the hull and wave surface of transverse section concerned E_r and variance of vertical relative velocities for the hull and wave surface of transverse section concerned E_v are obtained from the following formula:

$$E_r = 0.25(C_{pc}M_r)^2 / f_r$$

$$E_v = 0.25(\omega_e C_{pc}M_r)^2 / f_v$$

where: C_{pc} — correction factor of vertical relative motion probability, taken as 1.2;

ω_e — encounter frequency, in rad/s, obtained from the following formula:

$$\omega_e = \omega(1+\frac{0.4\omega V_c}{g})$$

ω — effective wave frequency based on 80% length of the ship, in rad/s, obtained from the following formula:

$$\omega = \sqrt{\frac{2\pi g}{0.8L}}$$

V_c — considered ship speed, in m/s, obtained from the following formula:

$$V_c = 0.5144V$$

where: V — defined in 1.1.2.27 of Chapter 1;

M_r — vertical relative motions for the hull and wave surface of the considered section, in m, obtained from the following formula:

$$M_r = H_{\min}\left[1 + \frac{4.5}{(C_b + 0.2)}\left(\frac{x_a}{L} - x_m\right)^2\right]$$

$H_{\min}$ — minimum wave height for calculation, in m, obtained from the following formula:

$$H_{\min} = \frac{0.0545}{k_m} L\left(C_b + 0.2\right)^{0.3} \exp(-0.0044L)$$

x_a — longitudinal position from the considered section to the after perpendicular, in m;

x_m — coefficient, obtained from the following formula, to be taken not less than 0.2;

$$x_m = 0.45 - \frac{0.309V}{\sqrt{gL}}$$

k_m — coefficient, obtained from the following formula:

$$k_m = 1 + \frac{4.5\left(0.5 - x_m\right)^2}{(C_b + 0.2)}$$

f_r 、 f_v — coefficient along the length of ship, obtained from the following formula, the intermediate value may be obtained by linear interpolation:

$$f_r、f_v = \begin{cases} \text{obtained according to Table 2.1.2(1),} & \text{for } L \leq 200\ m \\ \text{take values for 200m and 300m and interp olation according to the length of ship ,} & \text{for } 200m < L < 300m \\ \text{obtained according to Table 2.1.2(2),} & \text{for } L \geq 300\ m \end{cases}$$

Coefficient f_r , f_v Table 2.1.2 (1)

x_a / L	0.80	0.85	0.90	0.95
f_r	7.30	5.03	3.86	3.21

f_v	4.08	3.39	3.01	2.70

Coefficient f_r , f_v Table 2.1.2 (2)

x_a / L	0.80	0.85	0.90	0.95
f_r	3.15	2.52	2.21	2.08
f_v	1.00	1.00	1.00	1.00

2.2 Relative motion direct calculation

2.2.1 In calculation of the extreme value of slamming pressures, variance of vertical relative motions for the hull and wave surface of transverse section concerned E_r and vertical relative velocities E_v may be determined by direct calculation according to the requirements of this Section, namely the zero moment of motion response given respectively by spectrum analysis. In this case, the E_r and E_v of each section concerned are given by direct calculation, the slamming pressure P_B is replaced by the actual calculated value of extreme value of slamming pressures P_S.

2.2.2 For the direct strength assessment against bow bottom slamming, the loading condition with a minimum draught forward in navigation is to be identified from the Loading Manual.

2.2.3 Two-parameter P-M spectrum is adopted to model the wave power spectrum density function, which is given by the following formula:

$$S(\omega) = \frac{124H_S^2}{T_Z^4}\omega^{-5}\exp(-\frac{496}{T_Z^4}\omega^{-4})f_0(\theta)$$

where: H_s — significant wave height, in m;

T_z — mean zero-crossing period, in s;

ω — angular frequency of wave components, in rad/s;

$f_0(\theta)$ — wave spreading function, obtained from the following formula:

$$f_0(\theta) = \begin{cases} \frac{2}{\pi}\cos^2(\theta-\theta_m), & |\theta-\theta_m| < 90 \\ 0, & \text{Other values} \end{cases}$$

where: θ — extension wave direction, in degree;

θ_m — main wave direction, in degree.

2.2.4 The extreme value of slamming pressures is to be determined by short-term prediction approach and the significant wave height *Hs* is obtained from the following formulae:

$$H_S = \begin{cases} 8-0.6\left(\frac{300-L}{100}\right)^{1.5} & \text{m}, L < 300\text{m} \\ 8+0.6\left(\frac{L-300}{100}\right)^{1.5} & \text{m}, L \geq 300\text{m} \end{cases}$$

The average zero up-crossing wave period T_z and calculated navigation time t_n are to be selected in accordance with Table 2.2.4 and the intermediate values are to be obtained by interpolation.

Selection of sea wave conditions **Table 2.2.4**

Significant wave height H_S (m)	6.0	7.0	8.0	9.0
Average zero up-crossing wave period T_Z (s)	8.703	9.400	9.990	10.503
Calculated navigation time t_n (h)	41	35	35	35

2.2.5 The speed is to be taken as 0.75V.

2.2.6 The head sea and head oblique sea are to be considered, and interval between wave heading angles is not to be greater than 30 degrees.

2.2.7 The range of wave frequencies is to include 0.2 rad/s to 1.8 rad/s in increments taken as 0.05 rad/s.

2.2.8 Linear rolling damping may be determined by test or empirical formula, if not applicable, 5% of the critical rolling damping value may be taken.

2.2.9 Where direct calculation is adopted for relative motion, the slamming coefficient k_1 in 2.1.1 of this Appendix is obtained from the following formula:

$$k_1 = \exp(1.377 + 2.419a_1 - 0.873a_3 + 9.624a_5)$$

where: a_1, a_2, a_3 —the coefficient of three-parameter conformal mapping for the transverse section under draught d_1 to unit circle as follows:

$$Z_0 = U(\zeta + a_1\zeta^{-1} + a_3\zeta^{-3} + a_5\zeta^{-5})$$

Z_0 — section coordinate;

ζ — circle coordinate;

U — scale ratio, $U = \dfrac{d_1}{1 - a_1 + a_3 - a_5}$.

3 Strength Assessment

3.1 Slamming strength of shell plating

3.1.1 The pressure P_{cp} related to the ultimate capacity of shell plating is to be obtained from the following formula:

$$P_{cp} = \frac{12R_{eH}t_1^2}{a^2\left[3 - \dfrac{2}{\beta^2}\left(\sqrt{1+3\beta^2} - 1\right)\right]} \quad \text{MPa}$$

where: R_{eH} — yield stress of material, in N/mm^2;

t_1 — net thickness of plate panel, in mm;

a — length of the shorter side of the plate panel, in mm;

b — length of the longer side of the plate panel, in mm;

β — ratio between the sides, $\beta = b/a$.

3.1.2 When the relationship of the ultimate capacity P_{cp} and the extreme value of slamming pressures P_B is satisfied as below, the shell plating is considered to be with sufficient capacity against slamming:

$$1000\frac{P_{cp}}{P_B} \geqslant 0.75$$

where: P_B —slamming pressures, in kPa, see 2.1 of this Appendix.

3.2 Slamming strength of shell longitudinals

3.2.1 The pressure P_{cl} related to the ultimate capacity of shell longitudinals is to be obtained from the following formula:

$$P_{cl} = \frac{16R_{eH}W_T}{al^2} \quad \text{MPa}$$

where: R_{eH} — yield stress of material, in N/mm^2;

a — spacing of longitudinals, in mm;

l — span of longitudinals, in mm;

W_T — section modulus of longitudinals, including plate flange, in mm^3.

3.2.2 When the relationship of the ultimate capacity pressure P_{cl} and the extreme value of slamming pressures P_B is satisfied as below, the shell longitudinals are considered to be with sufficient capacity against slamming:

$$1000\frac{P_{cl}}{P_B} \geqslant 0.75$$

where: P_B —slamming pressures, in kPa, see 2.1 of this Appendix.

3.3 Slamming strength of bottom grillage

3.3.1 Structural FE model

(1) The longitudinal extent of the model is to include the calculation range as specified in 1.3 of this Appendix and at least extend to one web frame distance forward and aft. The transverse extent is to be selected as possible as to reduce the effect of boundary constraints on the response of bottom grillage. For example, the scope between the knuckle to the mid-line of the inner bottom may be selected for oil tankers and similar selection is applicable for other ships.

(2) Selection and meshing of elements are to comply with the requirements of Section 5, Chapter 1 of this PART.

(3) Strength evaluation is to be carried out for all primary members within the extent of strengthening of bottom forward.

(4) When the stress distribution or stiffness of members is affected by the openings on primary members, the methods may be adopted in accordance with the requirements of Section 5, Chapter 1 of this PART.

3.3.2 Boundary constraints

Floors and girders at the boundary of model are to be rigidly fixed.

3.3.3 Loads

According to the principle of slamming, the slamming pressure acts on the floor at the centre girder, the affected area is a square. The length of a side of this square S_1 is obtained from the following formula:

$$S_1 = \sqrt{1.1C_bLB \times 10^{-3}} \quad \text{m}$$

The extreme value of slamming pressure at each station of bow bottom will not occur at the same time, therefore the extreme value acting at each station is to be calculated respectively and the

maximum pressure of the bottom grillage is obtained. The distribution of slamming pressures on the floor is to be determined according to the following three situations:

(1) $S_1<S$:

The slamming pressure only acts on one floor, see Figure 3.3.3(1), the force Q acting on the floor in per unit length is to be calculated by the following formula:

$$Q = C_D P_B S_1 \quad \text{kN/m}$$

where: S — spacing of floors, in m;

P_B —slamming pressures, in kPa, see 2.1 of this Appendix;

C_D —dynamic slamming coefficient, to be taken as 0.8.

(2) $S<S_1<2S$:

The slamming pressure acts on two floors, see Figure 3.3.3(2), the force Q acting on the floor in per unit length is to be calculated by the following formula:

$$Q = 0.5 C_D P_B S_1 \quad \text{kN/m}$$

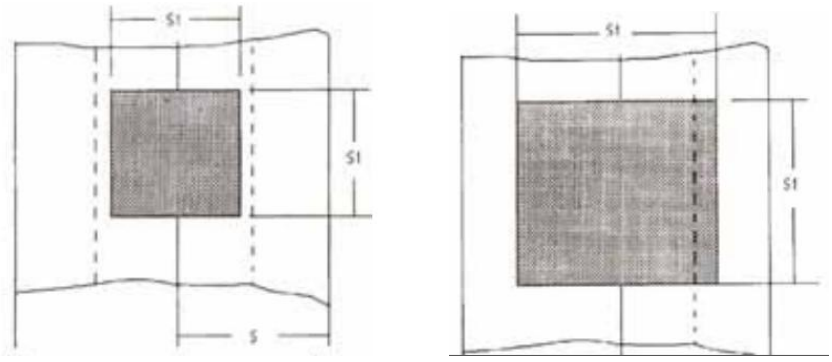
(3) $S_1>2S$:

The slamming pressure acts on three floors, the force Q_c acting on the intermediate floor in per unit length is to be calculated by the following formula:

$$Q_C = C_D P_B S \quad \text{kN/m}$$

The force Q_s acting on the side floor in per unit length is to be calculated by the following formula:

$$Q_S = 0.5 C_D P_B (S_1 - S) \quad \text{kN/m}$$



(1) (2)

Figure 3.3.3

3.3.4 Acceptance criteria

Permissible stress of direct calculation of slamming strength for bow bottom grillage is to be determined in accordance with Table 3.3.4.

Permissible Stress **Table 3.3.4**

Member	Positive stress of inner bottom plating σ (N/mm^2)	Positive stress of outer bottom plating σ (N/mm^2)	Shear stress τ (N/mm^2)	Equivalent stress σ_e (N/mm^2)
Girder	122/K	112/K	108/K	180/K
Floor	132/K	132/K	98/K	196/K

Note: K— material factor.

Appendix 5 BUCKLING STRENGTH ASSESSMENT OF SHIP STRUCTURAL ELEMENTS

SECTION 1 APPLICATION AND DEFINITIONS

Abbreviation

EPP —— Elementary plate panel, as defined in [1.2.3.1];

PSM —— Primary supporting member;

SP —— Stiffened panel, as defined in [1.2.3.3];

UP —— Unstiffened panel, as defined in[1.2.3.3].

1.1 Application

1.1.1 General Requirements

1.1.1.1 Relevant unified requirements concerning strength of ships

This Appendix establishes a general buckling assessment procedure as illustrated in Figure 1.1.1.1, and is to be applied in conjunction with Section 20 of Chapter 2 for hatch cover structures. The Section 20 of Chapter 2 is referred to as Relevant UR-S hereafter in this Appendix.

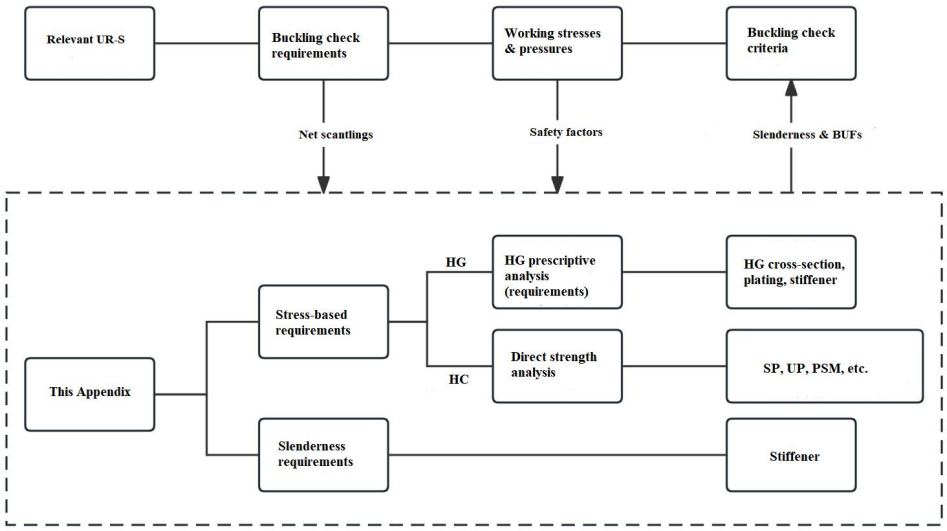


Figure 1.1.1.1 Overview of applying this UR in conjunction with Relevant UR-S

1.1.2 Application of this Appendix

1.1.2.1 Sections of this Appendix and application description

The buckling checks are to be performed according to:

(1) Section 1 for general definitions regarding buckling capacity, allowable buckling utilisation factors and buckling check criteria.

(2) Section 2 for the slenderness requirements of longitudinal and transverse stiffeners①.

(3) Section 3 for the prescriptive buckling requirements of plates, longitudinal and transverse stiffeners, primary supporting members and other structures subject to hull girder stresses②.

---

① The requirements in Section 2 of this Appendix are only applicable to stiffeners in the hatch cover structure.

② The requirements in Section 3 of this Appendix are not mandatory.

(4) Section 4 for direct strength analysis (usually by finite element method) buckling requirements of hatch cover structural members including plates, stiffeners and primary supporting members.
(5) Section 5 for the determination of buckling capacities of plate panels, stiffeners, primary supporting members and column structures.

1.1.2.2 Buckling assessment with this Appendix

For the buckling assessment of a ship hull girder, a hatch cover or other structural components, the slenderness requirements as defined in Section 2 and the buckling requirements as defined in Section 3 or Section 4 are to be checked as per the requirements of the applicable Relevant UR-S.

1.1.2.3 Alternative methods

This Appendix contains the general methods for the determination of buckling capacities of plate panels, stiffeners, primary supporting members, and columns. For special cases not covered in this Appendix, such as a whole plate structure with stiffeners in two directions (i.e., a stiffened panel with both primary and secondary stiffeners), other more advanced methods, such as finite element analysis methods, can be used with the consent of CCS.

1.2 Terminology and Assumptions

1.2.1 Buckling

1.2.1.1 Buckling strength

Buckling strength or capacity refers to the strength of a structure under in-plane compressions and/or shear and lateral load. Buckling strength with consideration of the buckling behaviour in [1.2.1.2] gives a lower bound estimate of ultimate capacity, or the maximum load a structural member can carry without suffering major permanent set.

For each structural member, its buckling strength is to be taken as corresponding to the most unfavourable or critical buckling mode.

1.2.1.2 Buckling behaviour

Buckling strength assessment takes into account both elastic buckling and post-buckling behaviours. Post-buckling can consider the internal redistribution of loads depending on the load situation, slenderness and type of structure. Such as for the buckling assessment of plates, generally its positive elastic post-buckling effect can be utilized.

As such, for slender structures, the calculated buckling strength is typically higher than the ideal elastic buckling stress (minimum eigenvalue). Accepting elastic buckling of slender plate panels implies that large elastic deflections and reduced in-plane stiffness may occur at higher buckling utilisation levels.

1.2.2 Net Scantling Approach

1.2.2.1 General requirements

Unless otherwise specified, all the scantling requirements, including slenderness requirements, in this Appendix are based on net scantlings obtained by removing full corrosion addition t_c from the gross offered thicknesses.

1.2.2.2 Corrosion addition

Corrosion addition t_c referred to in this Appendix is defined in the Relevant UR-S.

1.2.2.3 Stress calculation models

The structural models used for the calculation of stresses to be applied for buckling assessment, which are usually based on net scantlings, are defined in the Relevant UR-S.

1.2.3 Structural Idealisation

1.2.3.1 Elementary plate panel (EPP)

An elementary plate panel (EPP) is the unstiffened part of the plating between stiffeners and/or primary supporting members. The plate panel length, *a*, and breadth, *b*, of the EPP are defined respectively as the longest and shortest plate edges, as shown in Figure 1.2.3.1.

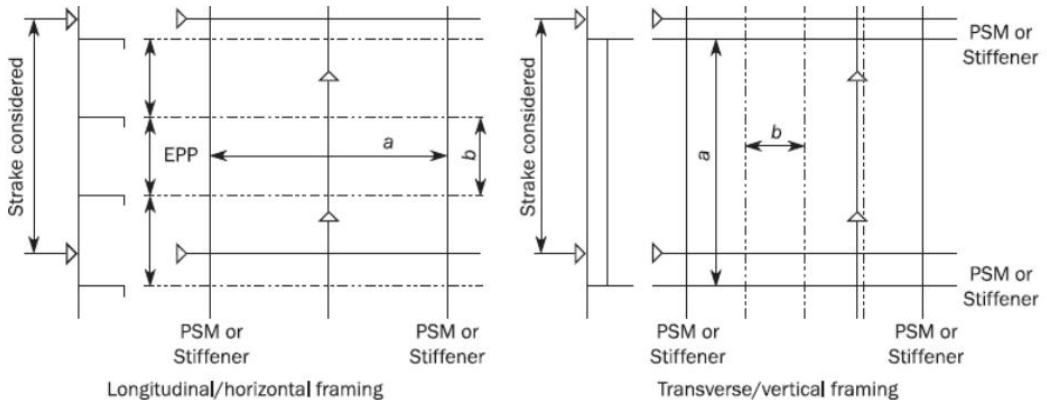

Figure 1.2.3.1 Elementary plate panel (EPP) definition

1.2.3.2 Standard types of stiffeners

Definitions of the cross-sectional dimensions of typical stiffener types are shown in Figure 1.2.3.2(1), which are flat bars, bulb flats, angles, L2 and T bars. If applicable, other types of stiffeners can be idealized to one of the typical types in Figure 1.2.3.2(1) for buckling check. For the U-type stiffener which is usually fitted in some hatch covers, the definition of its cross-sectional dimensions is shown in Figure 1.2.3.2(2).

Unless otherwise specified, the full span or full length *l*, in mm, of a stiffener is to be used for buckling check, which equals to the spacing between primary supporting members.

Symbolic dimensions of the cross-sections are as below:

b_1 —— Width of the attached plate enclosed by the U-type stiffener, in mm, as shown in Figure 1.2.3.2(2);

b_2 —— Width of the attached plate between adjacent U-type stiffeners, in mm, as shown in Figure 1.2.3.2(2);

b_f —— Width of the flange or face plate of the stiffener, in mm, as shown in Figure 1.2.3.2(1) and Figure 1.2.3.2(2);

$b_{f\text{-}out}$ —— Maximum distance, in mm, from mid thickness of the web to the flange edge, in mm, as shown in Figure 1.2.3.2(1);

d_f —— Breadth of the extended part of the flange for L2profiles, in mm, as shown in Figure 1.2.3.2(1);

e_f —— Distance from attached plating to centre of flange, in mm, as shown in Figure 1.2.3.2(1). For its detailed definition, refer to Section 5, Symbols;

h_w —— Depth of stiffener web, in mm, as shown in Figure 1.2.3.2(1) and Figure 1.2.3.2(2);

t_f —— Net flange thickness, in mm;

t_p —— Net thickness of plate, in mm;

t_w —— Net web thickness, in mm.

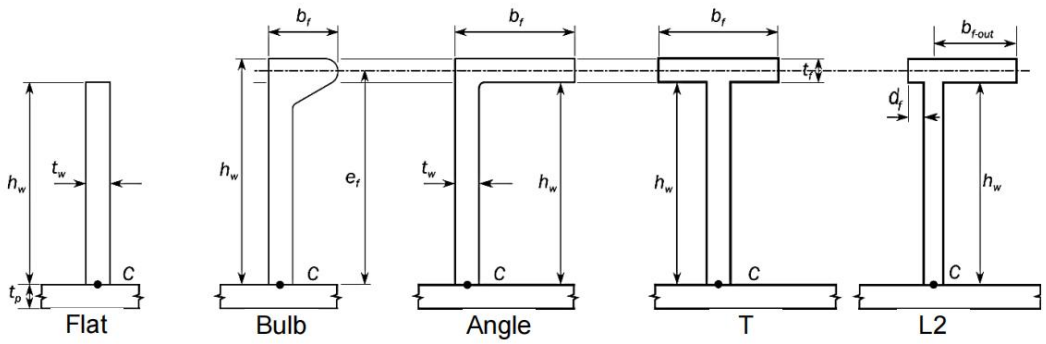

Figure 1.2.3.2(1) Dimensions of typical stiffener cross sections

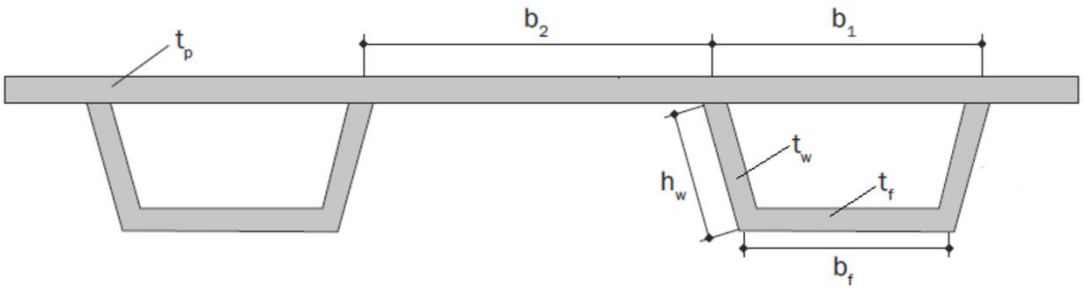

Figure 1.2.3.2(2) Dimensions of a U-type stiffener cross section

1.2.3.3 Stiffened panel (SP) and unstiffened panel (UP)

For a panel with relatively strong interactive effect between the stiffener and its attached plate, each stiffener with its attached plate as a whole is to be modelled as a stiffened panel (SP), so as to be able to consider both of its local and global buckling modes.

However, for an EPP, if its buckling strength can be checked without considering its interactive effect with stiffeners fitted along its edges, it is to be modelled as an unstiffened panel (UP).

1.2.4 Sign Convention

1.2.4.1 Stresses

In this Appendix, compressive and shear stresses are to be taken as positive, tension stresses are to be taken as negative.

1.3 Assessment Methods and Acceptance Criteria

1.3.1 Assessment Methods

1.3.1.1 Method A and Method B

The buckling assessment is to be carried out according to one of the following two methods taking into account different boundary condition types:

(1) Method A: All the edges of the EPP are forced to remain straight (but free to move in the in-plane directions) due to the surrounding structure/neighbouring plates.

(2) Method B: The edges of the EPP are not forced to remain straight due to low in-plane stiffness at the edges and/or no surrounding structure/neighbouring plates.

1.3.1.2 SP-A、SP-B、UP-A and UP-B models

For the buckling assessment of the stiffened panel (SP) and unstiffened panel (UP) structural models defined in [1.2.3.3], with application of either Method A or Method B for the plate buckling assessment, the following four buckling assessment models are established:

(1) SP-A: a stiffened panel with application of Method A.

(2) SP-B: a stiffened panel with application of Method B.

(3) UP-A: an unstiffened panel with application of Method A.

(4) UP-B: an unstiffened panel with application of Method B.

1.3.2 Buckling Utilisation Factor

1.3.2.1 The utilisation factor, η, is defined as the ratio between the applied loads and the corresponding buckling capacity.

1.3.2.2 For combined loads, the utilisation factor, η_{act}, is to be defined as the ratio of the applied equivalent stress and the corresponding buckling capacity, as shown in Figure 1.3.2.2, and is to be taken as:

$$\eta_{act} = \frac{W_{act}}{W_U} = \frac{1}{\gamma_c}$$

where:

W_{act} —— Equivalent applied stress. The actual applied stresses are given in Section 3 and Section 4 respectively for buckling assessment by prescriptive and direct strength analysis;

W_U —— Equivalent buckling capacity. For plates and stiffeners, their respective buckling or ultimate capacities are given in Section 5;

γ_c —— Stress multiplier factor at failure.

For each typical failure mode, the corresponding buckling capacity of the panel is calculated by applying the actual stress combination and then increasing or decreasing the stresses proportionally until collapse occurs, i.e., when the increased or decreased stresses are on a buckling strength interaction curve or surface.

Figure 1.3.2.2 illustrates the buckling capacity and the buckling utilisation factor of a structural member subject to σ_x and σ_y stresses.

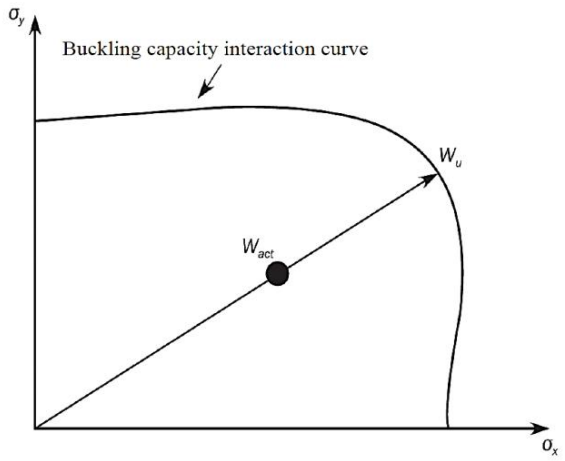

Figure 1.3.2.2 Illustration of buckling capacity and buckling utilisation factor

1.3.3 Allowable Buckling Utilisation Factor

1.3.3.1 The allowable buckling utilisation factor η_{all} is to be taken according to the Relevant UR-S.

1.3.4 Buckling Acceptance Criteria

1.3.4.1 A structural member is considered to have an acceptable buckling strength if it satisfies the following criterion:

$$\eta_{act} \leq \eta_{all}$$

where:

η_{act} —— Buckling utilisation factor based on the applied stress, defined in [1.3.2.2];

η_{all} —— Allowable buckling utilisation factor, as defined in [1.3.3.1].

SECTION 2 SLENDERNESS REQUIREMENTS

Symbols

For symbols not defined in this section, refer to Section 1, [1.2.3.2].

R_{eH} —— Specified minimum yield stress of the structural member being considered, in N/mm^2.

2.1 General Requirements

2.1.1 Introduction

2.1.1.1 The stiffener elements except for U-type stiffeners are to comply with the applicable slenderness and proportion requirements given in this Section.

2.2 Stiffeners

2.2.1 Proportions of Stiffeners

2.2.1.1 Net thickness of all stiffener types

The net thickness of stiffeners is to satisfy the following criteria:

(1) Stiffener web plate:

$$t_w \geq \frac{h_w}{C_w}\sqrt{\frac{R_{eH}}{235}}$$

(2) Flange:

$$t_f \geq \frac{b_{f-out}}{C_f}\sqrt{\frac{R_{eH}}{235}}$$

where:

C_w, C_f —— Slenderness coefficients given in Table 2.2.1.1.

Slenderness Coefficient **Table 2.2.1.1**

Type of Stiffener	C_w	C_f
Angle and L2 bars	75	12
T-bars	75	12
Bulb flats	45	-
Flat bars	22	-

If requirement (2) is not fulfilled, the effective free flange outstand, in mm, used in strength assessment including the calculation of actual net section modulus, is to be taken as:

$$b_{f-out-max} = C_f t_f \sqrt{\frac{235}{R_{eH}}}$$

For built-up profile where the relevant yielding strength for the web of built-up profile without the edge stiffener is acceptable, as an alternative the web can be assessed according to the web requirements of Angle and L2 bars in Table 2.2.1.1, and the edge stiffener can be assessed as a flat bar stiffener according to [2.2.1.1]. The requirement to flange in [2.2.1.2] shall still apply.

2.2.1.2 Net dimensions of angle and T-bars

The total flange breadth, b_f, in mm, for angle and T-bars is to satisfy the following criterion:

$$b_f \geq 0.2h_w$$

2.3 Primary Supporting Members

2.3.1 Proportions and Stiffness

2.3.1.1 Proportions of web plate and flange

The scantlings of webs and flanges of primary supporting members are to comply with the relevant requirements of [4.1], Section 2, Chapter 8, PART NINE of the Rules.

SECTION 3 BUCKLING REQUIREMENTS FOR HULL GIRDER PRESCRIPTIVE ANALYSIS

Symbols

η_{all} : Allowable buckling utilisation factor, as defined in Section 1, [1.3.3.1].

LCP：Load calculation point, as defined in [3.1.2.1].

3.1 General Requirements

3.1.1 Introduction

3.1.1.1 This Section applies to plate panels including plane and curved plate panels, stiffeners and corrugation of longitudinal corrugated bulkheads subject to hull girder compression and shear stresses.

3.1.1.2 The ship longitudinal extent where the buckling check is performed for structural elements subject to hull girder stresses is to be in accordance with the Relevant UR-S.

3.1.1.3 Design load sets: The buckling check is to be performed for all design load sets corresponding to the design loading conditions defined in the Relevant UR-S with the most unfavourable pressure combinations.

For each design load set, for all static and dynamic load cases, the lateral pressure is to be determined at the load calculation point defined in [3.1.2.1], and is to be applied together with the hull girder stress combinations defined in the Relevant UR-S.

3.1.2 Definitions

3.1.2.1 Load calculation point

The load calculation points (LCP) for both elementary plate panels (EPP) and stiffeners are defined as follows:

(1) LCP for hull girder stresses of EPP

The hull girder stresses for EPP are to be calculated at the load calculation points defined in Table 3.1.2.1.

Load calculation points (LCP) coordinates for plate buckling assessment

Table 3.1.2.1

LCP coordinates	Hull girder bending stress		Hull girder shear stress
	Non horizontal plating	Horizontal plating	
x coordinate	Mid-length of the EPP		
y coordinate	Both upper and lower ends of the EPP (points A1 and A2 in Figure 3.1.2.1(1))	Outboard and inboard ends of the EPP (points A1 and A2 in Figure 3.1.2.1(1))	Mid-point of EPP (point B in Figure 3.1.2.1(1))
z coordinate	Corresponding to *x* and *y* values		

(2) LCP for hull girder stresses of longitudinal stiffeners

The hull girder stresses for longitudinal stiffeners are to be calculated at the following load calculation point:

① at the mid length of the considered stiffener;

② at the intersection point between the stiffener and its attached plate.

(3) LCP for pressure of horizontal stiffeners

The load calculation point for the pressure is located at:

① middle of the full length, *l*, of the considered stiffener;

② the intersection point between the stiffener and its attached plate.

(4) LCP for pressure of non-horizontal stiffeners

The lateral pressure, *P* is to be calculated as the maximum between the value obtained at middle of the full length, *l*, and the value obtained from the following formulae:

$P = \frac{p_U + p_L}{2}$, when the upper end of the vertical stiffener is below the lowest zero pressure level;

$P = \frac{l_1}{l}\frac{p_L}{2}$, when the upper end of the vertical stiffener is at or above the lowest zero pressure level.

where: l_1 —— Distance, in m, between the lower end of vertical stiffener and the lowest zero pressure level;

p_U, p_L ——Lateral pressure at the upper and lower end of the vertical stiffener span, *l*, respectively.

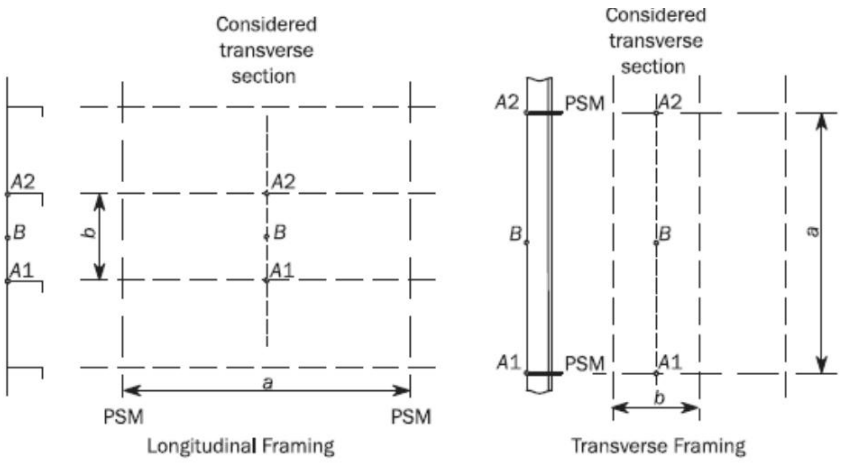

Figure 3.1.2.1(1) LCP for plate buckling assessment (PSM means the primary supporting members)

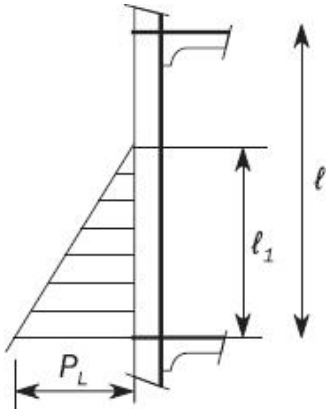

Figure 3.1.2.1(2) Definition of pressure for vertical stiffeners

3.1.3 Equivalent plate panels

3.1.3.1 Longitudinal stiffening with varying plate thickness

In longitudinal stiffening arrangement, when the plate thickness varies over the width b, of a plate panel (EPP), the buckling check is to be performed for an equivalent plate panel width,combined with the smaller plate thickness, t_1. The width of this equivalent plate panel, b_{eq}, in mm, is defined by the following formula:

$$b_{eq} = l_1 + l_2(\frac{t_1}{t_2})^{1.5}$$

where: l_1——Width of the part of the plate panel with the smaller plate thickness, t_1, in mm, as defined in Figure 3.1.3.1;

l_2—— Width of the part of the plate panel with the greater plate thickness, t_2, in mm, as defined in Figure 3.1.3.1.

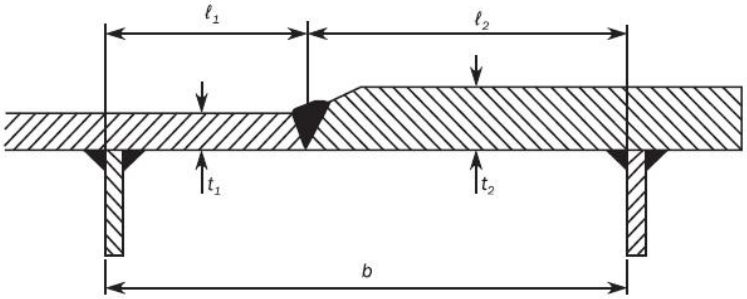

Figure 3.1.3.1 Plate thickness change over the width

3.1.3.2 Transverse stiffening with varying plate thickness

In transverse stiffening arrangement, when an EPP is made with different thicknesses, the buckling check of the plate and stiffeners is to be made for each thickness considered constant on the EPP, the stresses and pressures being estimated for the EPP at the LCP.

3.1.3.3 Plate panel with different materials

When the plate panel is made of different materials, the minimum yield strength is to be used for the buckling assessment.

3.2 Buckling Criteria

3.2.1 Overall Stiffened Panel

3.2.1.1 The buckling strength of overall stiffened panels is to satisfy the following criterion:

$$\eta_{overall} \leq \eta_{all}$$

where: $\eta_{overall}$ ——Maximum overall buckling utilisation factor as defined in Section 5, [5.2.1].

3.2.2 Plates

3.2.2.1 The buckling strength of elementary plate panels is to satisfy the following criterion:

$$\eta_{plate} \leq \eta_{all}$$

where: η_{plate} ——Maximum plate buckling utilisation factor as defined in Section 5, [5.2.2] where SP-A model is to be used.

For the determination of η_{plate} of the vertically stiffened side shell plating of single side skin bulk carrier between hopper and topside tanks, the cases 12 and 16 of Section 5, Table 3 corresponding to the shorter edge of the plate panel clamped are to be considered together with a mean σ_y stress and $\varphi_y = 1$.

3.2.3 Stiffeners

3.2.3.1 The buckling strength of stiffeners or of side frames of single side skin bulk carriers is to satisfy the following criterion:

$$\eta_{stiffener} \leq \eta_{all}$$

where：$\eta_{stiffener}$ ——Maximum stiffener buckling utilisation factor as defined in Section 5, [5.2.3].

Note 1: This buckling check can only be fulfilled when the overall stiffened panel buckling check, as defined in [3.2.1], is satisfied.

Note 2: The buckling check of the stiffeners is only applicable to the stiffeners fitted along the long edge of the buckling panel.

3.2.4 Vertically Corrugated Longitudinal Bulkheads

3.2.4.1 The shear buckling strength of vertically corrugated longitudinal bulkheads is to satisfy the following criterion:

$$\eta_{shear} \leq \eta_{all}$$

where: η_{shear} —— Maximum shear buckling utilisation factor, defined as

$$\eta_{shear} = \frac{\tau_{bhd}}{\tau_c} \ ;$$

τ_{bhd} ——Shear stress, in N/mm^2, in the bulkhead taken as the hull girder shear stress defined in the Relevant UR-S;

τ_c —— Shear critical stress, in N/mm^2, as defined in Section 5, [2.2.3].

3.2.5 Horizontally Corrugated Longitudinal Bulkheads

3.2.5.1 Each corrugation unit within the extension of half flange, web and half flange (i.e. single corrugation as shown in grey in Figure 3.2.5.1) is to satisfy the following criterion:

$$\eta_{column} \leq \eta_{all}$$

where: η_{column}—— Overall column buckling utilisation factor, as defined in Section 5, [5.3.1].

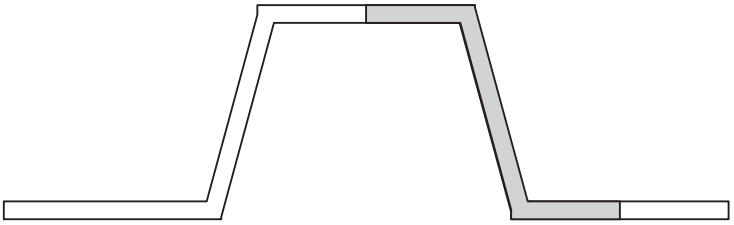

Figure 3.2.5.1 Single corrugation

SECTION 4 BUCKLING REQUIREMENTS FOR DIRECT STRENGTH ANALYSIS OF HATCH COVERS

Symbols

R_{eH_P}——Yield stress of the plate panel, as defined in [4.2.1.3];

R_{eH_S}——Yield stress of the stiffener, as defined in [4.2.1.3];

α—— Aspect ratio of the plate panel as defined in the Symbol list of Section 5;

η_{all} ——Allowable buckling utilisation factor, as defined in Section 1, [1.3.3.1].

4.1 General Requirements

4.1.1 Introduction

4.1.1.1 The requirements of this Section apply to the buckling assessment of hatch cover structural members based on direct strength analysis (usually by finite element method) and subjected to normal stress, shear stress and lateral pressure.

4.1.1.2 All structural elements in the direct strength analysis carried out according to the Relevant UR-S are to be assessed individually. The buckling checks are to be performed for the following structural elements:

- Stiffened and unstiffened panels.
- Web plate in way of openings.

4.2 Stiffened and Unstiffened Panels

4.2.1 General Requirements

4.2.1.1 The plate panel of a hatch cover structure is to be modelled as stiffened panel or unstiffened panel, with either Method A or Method B as defined in Section 1, [1.3.1.1] to be used for the calculation of the plate buckling capacity, which in combination is also equivalent to use the buckling assessment models defined in Section 1, [1.3.1.2].

4.2.1.2 Average thickness of plate panel

For FE analysis, where the plate thickness along a plate panel is not constant, the panel used for the buckling assessment is to be modelled with a weighted average thickness taken as:

$$t_{avr} = \frac{\sum_1^n A_i t_i}{\sum_1^n A_i}$$

where: A_i——Area of the *i*-th plate element;

t_i ——Net thickness of the *i*-th plate element;

n ——Number of finite elements defining the buckling plate panel.

4.2.1.3 Yield stress of the plate panel and stiffener

The panel yield stress R_{eH_P} is taken as the minimum value of the specified yield stresses of the elements within the plate panel.

The stiffener yield stress R_{eH_S} is taken as the minimum value of the specified yield stress of the elements within the stiffener.

4.2.2 Stiffened Panels

4.2.2.1 For a stiffened panel (SP), each stiffener with attached plate is to be idealized as a stiffened panel model of the extent defined in the Relevant UR-S.

4.2.2.2 If the stiffener properties or stiffener spacing varies within the stiffened panel, the calculations are to be performed separately for all configurations of the panels, i.e. for each stiffener and plate between the stiffeners. Plate thickness, stiffener properties and stiffener spacing at the considered location are to be assumed for the whole panel.

4.2.2.3 The buckling check of the stiffeners of stiffened panels is only applicable to the stiffeners fitted along the longer side edges of the buckling panel.

4.2.3 Unstiffened Panels

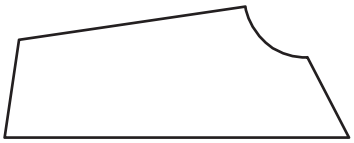
4.2.3.1 Irregular plate panel

In way of web frames, horizontal girders and brackets, the geometry of the panel (i.e. plate bounded by web stiffeners/face plate) may not have a rectangular shape. In this case, an equivalent rectangular panel is to be defined according to [4.2.3.2] for irregular geometry and [4.2.3.3] for triangular geometry and to comply with buckling assessment.

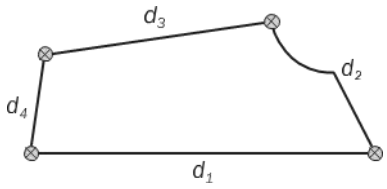
4.2.3.2 Equivalent EPP of an unstiffened panel with irregular geometry

Unstiffened panels with irregular geometry are to be idealised to equivalent panels for plate buckling assessment according to the following procedure:

(1) The four corners closest to a right angle, 90 deg, in the bounding polygon for the plate are identified.

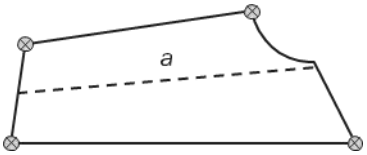


(2) The distances along the plate bounding polygon between the corners are calculated, i.e. the sum of all the straight-line segments between the end points.



(3) The pair of opposite edges with the smallest total length is identified, i.e. minimum of $d_1 + d_3$ and $d_2 + d_4$.

(4) A line joins the middle points of the chosen opposite edges (i.e. a mid-point is defined as the point at half the distance from one end). This line defines the longitudinal direction for the capacity model. The length of the line defines the length of the capacity model, a, measured from one end point.



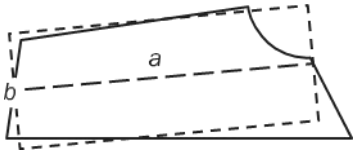
(5) The length of shorter side, *b,* in mm, is to be taken as:

$$b = \frac{A}{a}$$

where:

A —— Area of the plate in mm^2;

a —— Length defined in (4), in mm.

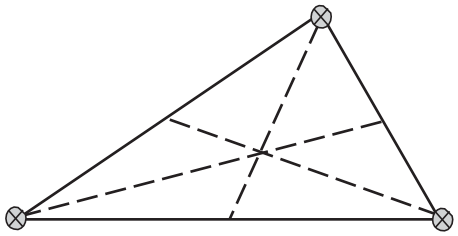


(6) The stresses from the direct strength analysis are to be transformed into the local coordinate system of the equivalent rectangular panel. These stresses are to be used for the buckling assessment.

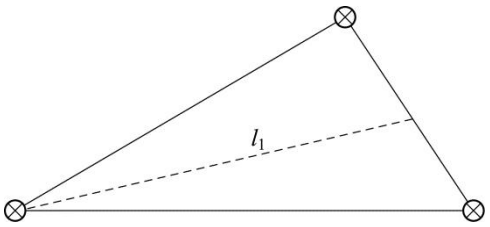
4.2.3.3 Modeling of an unstiffened plate panel with triangular geometry

Unstiffened panels with triangular geometry are to be idealised to equivalent panels for plate buckling assessment according to the following procedure:

(1) Medians are constructed as shown below:



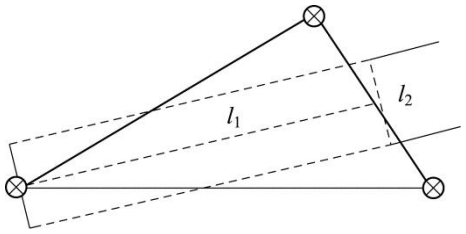
(2) The longest median is identified. This median the length of which is l_1, in mm, defines the longitudinal direction for the capacity model.



(3) The width of the model, l_2, in mm, is to be taken as:

$$l_2 = \frac{A}{l_1}$$

where: *A* —— Area of the plate, in mm^2.



(4) The lengths of shorter side, *b,* and of the longer side, *a*, in mm, of the equivalent rectangular plate panel are to be taken as:

$$b = \frac{l_2}{C_{tri}}$$

$$a = l_1 C_{tri}$$

where: $C_{tri} = 0.4\frac{l_2}{l_1} + 0.6$

(5) The stresses from the direct strength analysis are to be transformed into the local coordinate system of the equivalent rectangular panel and are to be used for the buckling assessment of the equivalent rectangular panel.

4.2.4 Reference Stress

4.2.4.1 The stress distribution is to be taken from the direct strength analysis according to the Relevant UR-S and applied to the buckling model.

4.2.4.2 For FE analysis, the reference stresses are to be calculated using the stress-based reference stresses as defined in Section 6.

4.2.5 Lateral Pressure

4.2.5.1 The lateral pressure applied to the direct strength analysis is also to be applied to the buckling assessment.

4.2.5.2 Where the lateral pressure is not constant over a buckling panel defined by a number of finite plate elements, an average lateral pressure, in N/mm^2, is calculated using the following formula:

$$P_{avr} = \frac{\sum_1^n A_i P_i}{\sum_1^n A_i}$$

where:

A_i—— Area of the *i*-th plate element, in mm^2;

P_i—— Lateral pressure of the *i*-th plate element, in N/mm^2;

n—— Number of the finite elements in the buckling panel.

4.2.6 Buckling Criteria

4.2.6.1 UP-A

The compressive buckling strength of UP-A is to satisfy the following criterion:

$$\eta_{UP-A} \leq \eta_{all}$$

where: η_{UP-A} —— Maximum buckling utilisation factor of plate, calculated according to Method A as defined in Section 5, [5.2.2].

4.2.6.2 UP-B

The compressive buckling strength of UP-B is to satisfy the following criterion:

$$\eta_{UP-B} \leq \eta_{all}$$

where: η_{UP-B} —— Maximum buckling utilisation factor of plate, calculated according to Method B as defined in Section 5, [5.2.2].

4.2.6.3 SP-A

The compressive buckling strength of SP-A is to satisfy the following criterion:

$$\eta_{SP-A} \leq \eta_{all}$$

where: $\eta_{SP\text{-}A}$—— Buckling utilisation factor of the stiffened panel, taken as the maximum of the buckling utilisation factors calculated as below:

- The overall stiffened panel buckling utilisaiton factor $\eta_{overall}$ as defined in Section 5, [5.2.1];
- The plate buckling utilisation factor η_{plate} calculated according to Method A as defined in Section 5 [5.2.2];
- The stiffener buckling utilisation factor $\eta_{stiffener}$ as defined in Section 5, [5.2.3] considering separately the properties (thickness, dimensions), the pressures defined in [4.2.5.2] and the reference stresses of each EPP at both sides of the stiffener.

Note 1: The stiffener buckling strength check can only be fulfilled when the overall stiffened panel capacity check, as defined in Section 5, [5.2.1], is satisfied.

4.2.6.4 SP-B

The compressive buckling strength of SP-B is to satisfy the following criterion:

$$\eta_{SP-B} \leq \eta_{all}$$

where: $\eta_{SP\text{-}B}$—— Buckling utilisation factor of the stiffened panel, taken as the maximum of the buckling utilisation factors calculated as below:

- The overall stiffened panel buckling utilisation factor $\eta_{overall}$ as defined in Section 5, [5.2.1];
- The plate buckling utilisation η_{plate} calculated according to Method B as defined in Section 5, [5.2.2];
- The stiffener buckling utilisation factor $\eta_{stiffener}$ as defined in Section 5, [5.2.3] considering separately the properties (thickness, dimensions), the pressures defined in [4.2.5.2] and the reference stresses of each EPP at both sides of the stiffener.

Note 1: The stiffener buckling strength check can only be fulfilled when the overall stiffened panel capacity check, as defined in Section 5, [5.2.1], is satisfied.

4.2.6.5 Web plate in way of openings

The web plate of primary supporting members with openings is to satisfy the following criterion:

$$\eta_{opening} \leq \eta_{all}$$

where: $\eta_{opening}$—— Maximum web plate utilisation factor in way of openings, calculated with the definition in Section 1, [1.3.2.2] and the stress multiplier factor at failure γ_c which can be calculated following the requirements in Section 5, [5.2.4].

SECTION 5 BUCKLING CAPACITY

Symbols

A_p —— Net sectional area of the stiffener attached plating, in mm^2, taken as:

$A_p = st_p$;

A_s —— Net sectional area of the stiffener without attached plating, in mm^2;

a —— Length of the longer side of the plate panel, in mm;

b —— Length of the shorter side of the plate panel, in mm;

b_{eff} —— Effective width of the attached plating of a stiffener, in mm, as defined in [5.2.3.5];

b_{eff1} —— Effective width of the attached plating of a stiffener, in mm, without the shear lag effective taken as:

(1) For $\sigma_x > 0$,

① For prescriptive assessment:

$$b_{eff1} = \frac{C_{x1}b_1 + C_{x2}b_2}{2}$$

② For FE analysis:

$$b_{eff1} = C_x b$$

(2) For $\sigma_x \leq 0$,

$$b_{eff1} = b;$$

b_f —— Breadth of the stiffener flange, in mm;

b_1, b_2 —— Width of plate panel on each side of the considered stiffener, in mm. For stiffened panels fitted with U-type stiffeners, b_1 and b_2 are as defined in Section 1, Figure 1.2.3.2(2);

C_{x1}, C_{x2} —— Reduction factor defined in Table 5.2.2.3 calculated for the EPP1 and EPP2 on each side of the considered stiffener according to case 1;

d —— Length of the side parallel to the cylindrical axis of the cylinder corresponding to the curved plate panel as shown in Table 5.2.2.6, in mm;

e_f —— Distance from attached plating to center of flange, in mm, as shown in Section 1, Figure 1.2.3.2(1), to be taken as:

$e_f = h_w$ for flat bar profile

$e_f = h_w - 0.5t_f$ for bulb profile

$e_f = h_w + 0.5t_f$ for angle, L2 and T profiles.

F_{long} —— Coefficient defined in [5.2.2.4];

F_{tran} —— Coefficient defined in [5.2.2.5];

h_w —— Depth of stiffener web, in mm, as shown in Section 1, Figure 1.2.3.2(1);

l —— Span, in mm, of stiffener equal to spacing between primary supporting members of span of side frame equal to the distance between the hopper tank and top wing tank in way of the side shell;

R —— Radius of curved plate panel, in mm;

R_{eH_P} —— Specified minimum yield stress of the plate, in N/mm^2;

R_{eH_S} —— Specified minimum yield stress of the stiffener, N/mm^2;

S —— Partial safety factor, unless otherwise specified in the Relevant UR-S, to be taken as 1.0;

t_p —— Net thickness of plate panel, in mm;

t_w —— Net stiffener web thickness, in mm;

t_f —— Net flange thickness, in mm;

x-axis —— Local axis of a rectangular buckling panel parallel to its long edge;

y-axis —— Local axis of a rectangular buckling panel perpendicular to its long edge;

α —— Aspect ratio of the plate panel, defined in Table 5.2.2.3, to be taken as: $\alpha = \frac{a}{b}$;

β —— Coefficient taken as: $\beta = \frac{1-\psi}{\alpha}$;

ω —— Coefficient taken as: $\omega = min\,(3, \alpha)$;

σ_x —— Normal stress applied on the edge along *x*-axis of the buckling panel, in N/mm^2;

σ_y —— Normal stress applied on the edge along *y*-axis of the buckling panel, in N/mm^2;

σ_1 —— Maximum normal stress along a panel edge, in N/mm^2;

σ_2 —— Minimum normal stress along a panel edge, in N/mm^2;

σ_E —— Elastic buckling reference stress, in N/mm^2, to be taken as:

(1) For the application of the limit state of plane plate panels according to [5.2.2.1]:

$$\sigma_E = \frac{\pi^2 E}{12(1-\nu^2)}\left(\frac{t_p}{b}\right)^2$$

(2) For the application of the limit state of curved plate panels according to [5.2.2.6]:

$$\sigma_E = \frac{\pi^2 E}{12(1-\nu^2)}\left(\frac{t_p}{d}\right)^2;$$

τ —— Applied shear stress, in N/mm^2;

τ_c —— Buckling strength in shear, in N/mm^2;

ψ —— Edge stress ratio to be taken as: $\psi = \frac{\sigma_2}{\sigma_1}$;

γ —— Stress multiplier factor acting on loads. When the factor is such that the loads reach the interaction formulae, $\gamma = \gamma_c$;

γ_c —— Stress multiplier factor at failure;

γ_{GEB} —— Stress multiplier factor of global elastic buckling capacity.

5.1 General Requirements

5.1.1 Introduction

5.1.1.1 This Section contains the methods for determination of the buckling capacities of plate panels, stiffeners, primary supporting members and columns.

5.1.1.2 For the application of this Section, the stresses σ_x, σ_y and τ applied on the structural members are defined in:

(1) Section 3 for hull girder prescriptive buckling requirements.

(2) Section 4 for direct strength analysis buckling requirements of hatch covers.

5.1.1.3 Buckling capacity

The buckling capacity is calculated by applying the actual stress combination and then increasing or decreasing the stresses proportionally until the interaction formulae defined in [5.2.1.1], [5.2.2.1] and [5.2.3.4] of this Section are equal to 1.0, respectively.

5.1.1.4 Buckling utilisation factor

The buckling utilisation factor of the structural member is equal to the highest utilisation factor obtained for the different buckling modes.

5.1.1.5 Lateral pressure

The lateral pressure is to be applied and considered as constant for the calculation of buckling capacities as defined in [5.1.1.3].

5.2 Buckling Capacity of Plate Panels

5.2.1 Overall Stiffened Panels

5.2.1.1 The elastic stiffened panel limit state is based on the following interaction formula, which sets a precondition for the buckling check of stiffeners in accordance with [5.2.3.4]:

$$\frac{\gamma_c}{\gamma_{GEB}} = 1$$

with the corresponding buckling utilisation factor defined as:

$$\eta_{overall} = \frac{1}{\gamma_c}$$

where: the stress multiplier factor of global elastic buckling capacity, γ_{GEB}, are to be calculated based on the following formulae:

$\gamma_{GEB} = \gamma_{GEB,bi+\tau}$ for $\tau \neq 0$ and ($\sigma_x > 0$ or $\sigma_y > 0$) ;

$\gamma_{GEB} = \gamma_{GEB,bi}$ for $\tau = 0$ and ($\sigma_x > 0$ or $\sigma_y > 0$) ;

$\gamma_{GEB} = \gamma_{GEB,\tau}$ for $\tau \neq 0$ and ($\sigma_x \leq 0$ or $\sigma_y \leq 0$) .

where: $\gamma_{GEB,bi+\tau}$, $\gamma_{GEB,bi}$ and $\gamma_{GEB,\tau}$ are stress multiplier factors of the global elastic buckling capacity for different load combinations as defined in [5.2.1.2], [5.2.1.3] and [5.2.1.4], respectively. For the calculation of $\gamma_{GEB,bi+\tau}$, $\gamma_{GEB,bi}$ and $\gamma_{GEB,\tau}$, neither σ_x nor σ_y are to be taken less than 0.

σ_x, σ_y —— Applied normal stress to the plate panel, in N/mm^2, to be taken as defined in [5.2.2.7];

τ —— Applied shear stress, in N/mm^2, to be taken as defined in [5.2.2.7].

5.2.1.2 The stress multiplier factor $\gamma_{GEB,bi}$ for the stiffened panel subjected to biaxial loads is taken as:

$$\gamma_{GEB,bi} = \frac{\pi^2}{L_{B1}^2 L_{B2}^2} \frac{\left[D_{11}L_{B2}^4 + 2(D_{12} + D_{33})n^2 L_{B1}^2 L_{B2}^2 + n^4 D_{22} L_{B1}^4\right]}{L_{B2}^2 N_x + n^2 L_{B1}^2 N_y}$$

where:

N_x—— Load per unit length applied on the edge along *x*-axis of the stiffened panel, in N/mm, taken as

$N_x = \sigma_{x,av}(A_p + A_s)/s$

For stiffened panels fitted with U-type stiffeners, stiffener spacing *s* is taken as:

$s = b_1 + b_2$

Where b_1 and b_2 are as defined in Figure 5.3.1.4;

N_y—— Load per unit length applied on the edge along *y*-axis of the stiffened panel, in 方 N/mm, taken as:

$N_y = c\sigma_y t_p$;

L_{B1}—— Stiffener span, in mm, distance between primary supporting members, i.e.

$L_{B1} = l$;

L_{B2}—— Width of stiffened panel between stiffened panels, in mm, taken as 6 times of the stiffer spacing, i.e. $L_{B2} = 6s$;

n—— Number of half waves along the direction perpendicular to the stiffener axis. The factor $\gamma_{GEB,bi}$ is to be taken as the smallest value larger than 0.

c—— Factor taking into account the normal stress distribution in the panel boundaries acting perpendicular to the stiffener's axis:

$c = 0.5(1 + \Psi)$ for $0 \leq \Psi \leq 1$;

$c = \frac{1}{2(1-\Psi)}$ for $\Psi < 0$;

Ψ—— Edge stress ratio for case 2 according to Table 5.3.1.3;

$\sigma_{x,av}$—— Average stress, in MPa, for both plate and stiffener after Poisson correction, taken as:

$\sigma_{x,av} = \sigma_x - \nu c\sigma_y A_s/(A_p + A_s) \geq 0$ for $\sigma_x > 0$ and $\sigma_y > 0$

$\sigma_{x,av} = \sigma_x$ for $\sigma_x \leq 0$ or $\sigma_y \leq 0$;

$D_{11}, D_{12}, D_{22}, D_{33}$ —— Bending stiffness coefficients, in N·mm, of the stiffened panel, defined in general as:

$$\left.\begin{aligned} D_{11} &= \frac{EI_{eff}10^4}{s} \\ D_{12} &= \frac{Et_p^3\nu}{12(1-\nu^2)} \\ D_{22} &= \frac{Et_p^3}{12(1-\nu^2)} \\ D_{33} &= \frac{Et_p^3}{12(1+\nu)} \end{aligned}\right\}$$

For stiffened panels fitted with U-type stiffeners, D_{12} and D_{22} are defined as:

$$D_{22} = \frac{Et_p^3}{12(1-\nu^2)}\left[1.2 + 4.8 \times Min\left(1.0,\ \frac{b_1^2}{h_w(b_1+b_2)}\right) \times Min\left(1.0, \left(\frac{t_w}{t_p}\right)^3\right)\right]$$

$$D_{12} = \nu D_{22}$$

h_w—— Breadth of U-type stiffener web as defined in Figure 5.3.1.4;

I_{eff}——Moment of inertia, in cm^4, of the stiffener including the effective width of the attached plating, same as I defined in [5.2.3.4].

5.2.1.3 The stress multiplier factor $\gamma_{GEB,\tau}$, for the stiffened panel subjected to pure shear load is taken as:

$$\gamma_{GEB,\tau} = \frac{\sqrt[4]{D_{11}^3 D_{22}}}{(L_{B1}/2)^2 N_{xy}}\left[8.125 + 5.64\sqrt{\frac{(D_{12}+D_{33})^2}{D_{11}D_{22}}} - 0.6\frac{(D_{12}+D_{33})^2}{D_{11}D_{22}}\right] \quad \text{for } D_{11}D_{22} \geq (D_{12}+D_{33})^2$$

$$\gamma_{GEB,\tau} = \frac{\sqrt{2D_{11}(D_{12}+D_{33})}}{(L_{B1}/2)^2 N_{xy}}\left[8.3 + 1.525\frac{D_{11}D_{22}}{(D_{12}+D_{33})^2} - 0.493\frac{D_{11}^2 D_{22}^2}{(D_{12}+D_{33})^4}\right] \text{ for } D_{11}D_{22} < (D_{12}+D_{33})^2$$

where: $N_{xy} = \tau t_p$

5.2.1.4 The stress multiplier factor$\gamma_{GEB,bi+\tau}$, for the stiffened panel subjected to combined loads is taken as:

$$\gamma_{GEB,bi+\tau} = \frac{1}{2}{\gamma_{GEB,\tau}}^2\left[-\frac{1}{\gamma_{GEB,bi}} + \sqrt{\frac{1}{{\gamma_{GEB,bi}}^2} + 4\frac{1}{{\gamma_{GEB,\tau}}^2}}\right]$$

where: $\gamma_{GEB,bi}$ and $\gamma_{GEB,\tau}$ are as defined in [5.2.1.2] and [5.2.1.3], respectively.

5.2.2 Plates

5.2.2.1 Plate limit state

The plate limit state is based on the following interaction formulae:

$$\left(\frac{\gamma_{c1}\sigma_x S}{\sigma_{cx}}\right)^{e_0} - B\left(\frac{\gamma_{c1}\sigma_x S}{\sigma_{cx}}\right)^{\frac{e_0}{2}}\left(\frac{\gamma_{c1}\sigma_y S}{\sigma_{cy}}\right)^{\frac{e_0}{2}} + \left(\frac{\gamma_{c1}\sigma_y S}{\sigma_{cy}}\right)^{e_0} + \left(\frac{\gamma_{c1}|\tau|S}{\tau_c}\right)^{e_0} = 1$$

$$\left(\frac{\gamma_{c2}\sigma_x S}{\sigma_{cx}}\right)^{\frac{2}{\beta_p^{0.25}}} + \left(\frac{\gamma_{c2}|\tau|S}{\tau_c}\right)^{\frac{2}{\beta_p^{0.25}}} = 1 \text{ for } \sigma_x \geq 0$$

$$\left(\frac{\gamma_{c3}\sigma_y S}{\sigma_{cy}}\right)^{\frac{2}{\beta_p^{0.25}}} + \left(\frac{\gamma_{c3}|\tau|S}{\tau_c}\right)^{\frac{2}{\beta_p^{0.25}}} = 1 \text{ for } \sigma_y \geq 0$$

$$\frac{\gamma_{c4}|\tau|S}{\tau_c} = 1$$

with:

$$\gamma_c = Min\,(\gamma_{c1}, \gamma_{c2}, \gamma_{c3}, \gamma_{c4})$$

and the corresponding buckling utilisation factor defined as:

$$\eta_{plate} = \frac{1}{\gamma_c}$$

where:

σ_x, σ_y ____ Applied normal stress to the plate panel, in N/mm^2, to be taken as defined in [5.2.2.7];

τ ____ Applied shear stress to the plate panel, in N/mm^2;

σ_{cx}____ Ultimate buckling stress, in N/mm^2, in direction parallel to the longer edge of the buckling panel as defined in [5.2.2.3];

σ_{cy}____ Ultimate buckling stress, in N/mm^2, in direction parallel to the shorter edge of the buckling panel as defined in [5.2.2.3];

τ_c____ Ultimate buckling shear stress, in N/mm^2, as defined in [5.2.2.3];

$\gamma_{c1}, \gamma_{c2}, \gamma_{c3}, \gamma_{c4}$ Stress multiplier factors at failure for each of the above different limit states. γ_{c2} and γ_{c3} are only to be considered when $\sigma_x \geq 0$ and $\sigma_y \geq 0$ respectively.

B ____ Coefficient given in Table 5.2.2.1;

e_0____ Coefficient given in Table 5.2.2.1;

β_p____ Plate slenderness parameter taken as:

$\beta_p = \frac{b}{t_p}\sqrt{\frac{R_{eH_P}}{E}}$.

Definition of coefficients of B and e_0 Table 5.2.2.1

Applied stress	$\boldsymbol{B}$	$\boldsymbol{e_0}$
$\sigma_x \geq 0$ and $\sigma_y \geq 0$	$0.7 - 0.3\,\beta_p/\alpha^2$	$2/\beta_p^{0.25}$
$\sigma_x < 0$ or $\sigma_y < 0$	1.0	2.0

5.2.2.2 Reference degree of slenderness

The reference degree of slenderness is to be taken as:

$$\lambda = \sqrt{\frac{R_{eH_P}}{K\sigma_E}}$$

where: K——Buckling factor, as defined in Table 5.2.2.3 and Table 5.2.2.6.

5.2.2.3 Ultimate buckling stresses

The ultimate buckling stresses of plate panels, in N/mm^2, are to be taken as:

$$\sigma_{cx} = C_x R_{eH_P}$$

$$\sigma_{cy} = C_y R_{eH_P}$$

The ultimate buckling stress of plate panels subject to shear, in N/mm^2, is to be taken as:

$$\tau_c = C_\tau \frac{R_{eH_P}}{\sqrt{3}}$$

where: C_x, C_y, C_τ ——Reduction factors, as defined in Table 5.2.2.3.

For the 1st Equation of [5.2.2.1], when $\sigma_x < 0$ or $\sigma_y < 0$, the reduction factors are to be taken as :

$$C_x = C_y = C_\tau = 1$$

For other cases:

(1) For SP-A and UP-A, c_1 is calculated according to Table 5.2.2.3 by using

$$c_1 = \left(1 - \frac{1}{\alpha}\right) \geq 0$$

(2) For SP-B and UP-B, c_1 is calculated according to Table 5.2.2.3 by using

$$c_1 = 1$$

(3) For vertically stiffened single side skin of bulk carrier, c_1 is calculated according to Table 5.2.2.3 by using

$$c_1 = \left(1 - \frac{1}{\alpha}\right) \geq 0$$

(4) For corrugation of corrugated bulkheads, c_1 is calculated according to Table 5.2.2.3 by using

$$c_1 = \left(1 - \frac{1}{\alpha}\right) \geq 0$$

The boundary conditions for plates are to be considered as simply supported, see cases in ①, ② and ⑮ of Table 5.2.2.3. If the boundary conditions differ significantly from simple support, a more appropriate boundary condition can be applied according to the different cases of Table 5.2.2.3 with the consent of CCS.

5.2.2.4 Correction factor F_{long}

The correction factor F_{long} depending on the edge stiffener types on the longer side of the buckling panel is defined in Table 5.2.2.4. An average value of F_{long} is to be used for plate panels having different edge stiffeners. For stiffener types other than those mentioned in Table 5.2.2.4, the value of c is to be agreed by CCS. In such a case, value of c higher than those mentioned in Table 5.2.2.4 can be used, provided it is verified by buckling strength check of panel using non-linear FE analysis and deemed appropriate by CCS.

<tr><td colspan="5">Notes:
(1) t_w is the net web thickness, in mm, without the correction defined in [5.4.3.5] of this Section.
(2) b_1, b_2 and t_w are defined in Section 1, Figure 1.2.3.2(2).</td></tr>
</table>

5.2.2.5 Correction factorF_{tran}

The correction factor F_{tran} is to be taken as:

(1) For transversely frame EPP of single side skin bulk carrier, between the hopper and top wing tank:

① $F_{tran} = 1.25$ when the two adjacent frames are supported by one tripping bracket fitted in way of the adjacent plate panels;

② $F_{tran} = 1.33$ when the two adjacent frames are supported by two tripping brackets each fitted in way of the adjacent plate panels.

③ $F_{tran} = 1.15$ elsewhere.

(2) For the attached plate of a U-type stiffener fitted on a hatch cover:

$$F_{tran} = \text{Max}\left(3 - 0.08(F_{tran0} - 6)^2, 1.0\right) \le 2.25$$

where:

$$F_{tran0} = \text{Min}\left(\frac{b_2}{b_1} + \frac{6b_2^2}{\pi^2 h_w (b_1 + b_2)}\left(\frac{t_w}{t_p}\right)^3, 6\right) \text{ for EPP } b_2;$$

$$F_{tran0} = \text{Min}\left(\frac{b_1}{b_2} + \frac{6b_1^2}{\pi^2 h_w (b_2 + b_1)}\left(\frac{t_w}{t_p}\right)^3, 6\right) \text{ for EPP } b_1.$$

with b_1, b_2 and h_w as defined in Figure 1.2.3.2(2) of this Section.

Coefficient F defined in Case 2 of Table 5.2.2.3 is to be replaced by the following formula:

$$F = \left[1 - \left(\frac{K_y}{0.91F_{tran}} - 1\right)/\lambda_p^2\right]c_1 \geq 0$$

(3) For other cases, the correction factor F_{tran} is to be taken as 1.0.

5.2.2.6 Curved plate panels

This requirement for curved plate limit state is applicable when $R/t_p \leq 2500$. Otherwise, the requirement for plate limit state given in [5.2.2.1] of this Section is applicable.

The curved plate limit state is based on the following interaction formula:

$$\left(\frac{\gamma_c \sigma_{ax} S}{C_{ax} R_{eH_P}}\right)^{1.25} - 0.5 \cdot \left(\frac{\gamma_c \sigma_{ax} S}{C_{ax} R_{eH_P}}\right)\left(\frac{\gamma_c \sigma_{tg} S}{C_{tg} R_{eH_P}}\right) + \left(\frac{\gamma_c \sigma_{tg} S}{C_{tg} R_{eH_P}}\right)^{1.25} + \left(\frac{\gamma_c \tau \sqrt{3} S}{C_\tau R_{eH_P}}\right)^2 = 1.0$$

With the corresponding buckling utilisation factor defined as:

$$\eta_{curved_plate} = \frac{1}{\gamma_c}$$

where:

σ_{ax}—— Applied axial stress to the cylinder corresponding to the curved plate panel, in N/mm^2. In case of tensile axial stresses, $\sigma_{ax} = 0$;

σ_{tg}—— Applied tangential stress to the cylinder corresponding to the curved plate panel, in N/mm^2. In case of tensile tangential stresses, $\sigma_{tg} = 0$;

C_{ax}, C_{tg}, C_τ —— Buckling reduction factor of the curved plate panel, as defined in Table 5.2.2.6.

The stress multiplier factor, γ_c, of the curved plate panel need not be taken less than the stress multiplier factor, γ_c, for the expanded plane panel according to [5.2.2.1] of this Section.

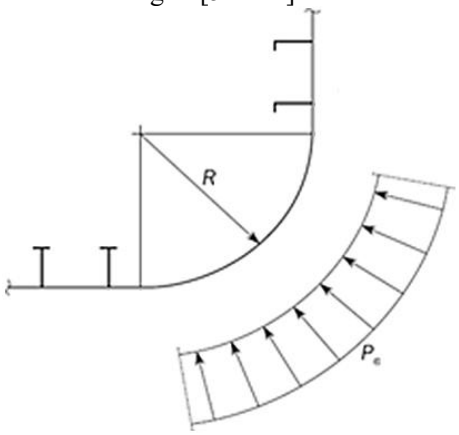

Figure 5.2.2.6 Transverse stiffened bilge plating

Buckling factor and reduction factor for curved plate panel with $R/t_p \leq 2500$ Table 5.2.2.6

Case	Aspect ratio	Buckling factor *K*	Reduction factor *C*
1	$\frac{d}{R} \leq 0.5\sqrt{\frac{R}{t_p}}$	$K = 1 + \frac{2}{3}\frac{d^2}{Rt_p}$	For general application $C_{ax} = 1$ for $\lambda \leq 0.25$

Case	Aspect ratio	Buckling factor K	Reduction factor C
	$\frac{d}{R} > 0.5\sqrt{\frac{R}{t_p}}$	$K = 0.267\frac{d^2}{Rt_p}\left[3 - \frac{d}{R}\sqrt{\frac{t_p}{R}}\right]$ $\geq 0.4\frac{d^2}{Rt_p}$	$C_{ax} = 1.233 - 0.933\lambda$ for $0.25 < \lambda \leq 1$ $C_{ax} = 0.3/\lambda^2$ for $1 < \lambda \leq 1.5$ $C_{ax} = 0.2/\lambda^2$ for $\lambda > 1.5$ For curved single fields, e.g. bilge strake, which are bounded by plane panels as shown in Figure 5.2.2.6: $C_{ax} = \frac{0.65}{\lambda^2} \leq 1.0$
2 	$\frac{d}{R} > 1.63\sqrt{\frac{R}{t_p}}$	$K = \frac{d}{\sqrt{Rt_p}} + 3\frac{(Rt_p)^{0.175}}{d^{0.35}}$	For general application: $C_{tg} = 1$ for $\lambda \leq 0.4$ $C_{tg} = 1.274 - 0.686\lambda$ for $0.4 < \lambda \leq 1.2$ $C_{tg} = \frac{0.65}{\lambda^2}$ for $\lambda > 1.2$ For curved single fields, e.g. bilge strake, which are bounded by plane panels as shown in Figure 5.2.2.6: $C_{tg} = \frac{0.8}{\lambda^2} \leq 1.0$
	$\frac{d}{R} > 1.63\sqrt{\frac{R}{t_p}}$	$K = 0.3\frac{d^2}{R^2} + 2.25\left(\frac{R^2}{dt_p}\right)^2$	
3 	$\frac{d}{R} \leq \sqrt{\frac{R}{t_p}}$	$K = \frac{0.6d}{\sqrt{Rt_p}} + \frac{\sqrt{Rt_p}}{d} - 0.3\frac{Rt_p}{d^2}$	As in load case 2
	$\frac{d}{R} \leq \sqrt{\frac{R}{t_p}}$	$K = 0.3\frac{d^2}{R^2} + 0.291\left(\frac{R^2}{dt_p}\right)^2$	
4 	$\frac{d}{R} \leq 8.7\sqrt{\frac{R}{t_p}}$	$K = \sqrt{3}\sqrt{28.3 + \frac{0.67d^3}{R^{1.5}t_p^{1.5}}}$	$C_\tau = 1$ for $\lambda \leq 0.4$; $C_\tau = 1.274 - 0.686\lambda$, for $0.4 < \lambda \leq 1.2$; $C_\tau = \frac{0.65}{\lambda^2}$ for $\lambda > 1.2$
	$\frac{d}{R} \leq 8.7\sqrt{\frac{R}{t_p}}$	$K = \sqrt{3}\frac{0.28d^2}{R\sqrt{Rt_p}}$	
Explanations for boundary conditions - - - - - - - - - - - - Plate edge free; ———— Plate edge simply supported; ▬▬▬ Plate edge clamped.			

5.2.2.7 Applied normal and shear stresses to plate panels

The normal stress, σ_x and σ_y, in N/mm^2, to be applied for the overall stiffened panel capacity and the plate panel capacity calculations as given in [5.2.1.1] and [5.2.2.1] respectively, are to be taken as follows:

(1) For FE analysis, the reference stresses as defined in Section 4, [4.2.4];

(2) For prescriptive assessment of the overall stiffened panel capacity and the plate panel capacity, the axial or transverse compressive stresses calculated according to the Relevant UR-S, at load calculation points of the considered stiffener or the considered elementary plate panel, as defined in (1) and (2) of Section 3, [3.1.2.1] respectively. However, in case of transverse stiffening arrangement, the transverse compressive stress used for the assessment of the overall stiffened panel capacity is to be taken as the

compressive stress calculated at load calculation points of the stiffener attached plating, as defined in (1) of Section 3, [3.1.2.1].

(3) For grillage analysis where the stresses are obtained based on beam theory, the stresses taken as:

$$\sigma_x = \frac{\sigma_{xb} + \nu\sigma_{yb}}{1 - \nu^2}$$

$$\sigma_y = \frac{\sigma_{yb} + \nu\sigma_{xb}}{1 - \nu^2}$$

where:

σ_{xb}, σ_{yb} —— Stress, in N/mm^2, from grillage beam analysis respectively along x and y axis of the plate attached to the PSN web.

The shear stress, τ, in N/mm^2, to be applied for the overall stiffened panel capacity and the plate panel capacity calculations as given in [5.2.1.1] and [5.2.2.1] respectively, are to be taken as follows:

① For FE analysis, the reference shear stresses as defined in Section 4, [4.2.4];

② For prescriptive assessment of the plate panel buckling capacity, the shear stresses calculated according to the Relevant UR-S, at load calculation points of the considered elementary plate panel, as defined in (1) of Section 3, [3.1.2.1];

③ For prescriptive assessment of the overall elastic stiffened panel buckling capacity, the shear stresses calculated according to the Relevant UR-S, at the following load calculation point:

(a) At the middle of the full span, *l*, of the considered stiffener;

(b) At the intersection point between the stiffener and its attached plating.

(4) For grillage beam analysis, $\tau = 0$ in the plate attached to the PSM web.

5.2.3 Stiffeners

5.2.3.1 Buckling modes

The following buckling modes are to be checked:

(1) Stiffener induced failure (*SI*);

(2) Associated plate induced failure (*PI*).

5.2.3.2 Web thickness of flat bar

For accounting the decrease of the stiffness due to local lateral deformation, the effective web thickness of flat bat stiffener, in mm, is to be used in [5.2.1] and [5.2.3.4] for the calculation of the net sectional area, A_s, the net section modulus, Z, and the moment of inertia, I, of the stiffener and is taken as:

$$t_{w_red} = t_w \left(1 - \frac{2\pi^2}{3}\left(\frac{h_w}{s}\right)^2 \left(1 - \frac{b_{eff1}}{s}\right)\right)$$

5.2.3.3 Idealisation of bulb profile

Bulb profiles are to be considered as equivalent angle profiles. The net dimensions of the equivalent built-up section are to be obtained from the following formulae:

$$h_w = h_w^{'} - \frac{h_w^{'}}{9.2} + 2$$

$$b_f = \alpha\left(t_w^{'} + \frac{h_w^{'}}{6.7} - 2\right)$$

$$t_f = \frac{h_w^{'}}{9.2} - 2$$

$$t_w = t_w^{'}$$

where: $h_w^{'}, t_w^{'}$——Net height and thickness of a bulb section, in mm, as shown in Figure 5.2.3.3;

α ——Coefficient equal to:

$$\alpha = 1.1 + \frac{\left(120 - h_w^{'}\right)^2}{3000} \quad \text{for } h_w^{'} \le 120$$

$$\alpha = 1.0 \quad \text{for } h_w^{'} > 120.$$

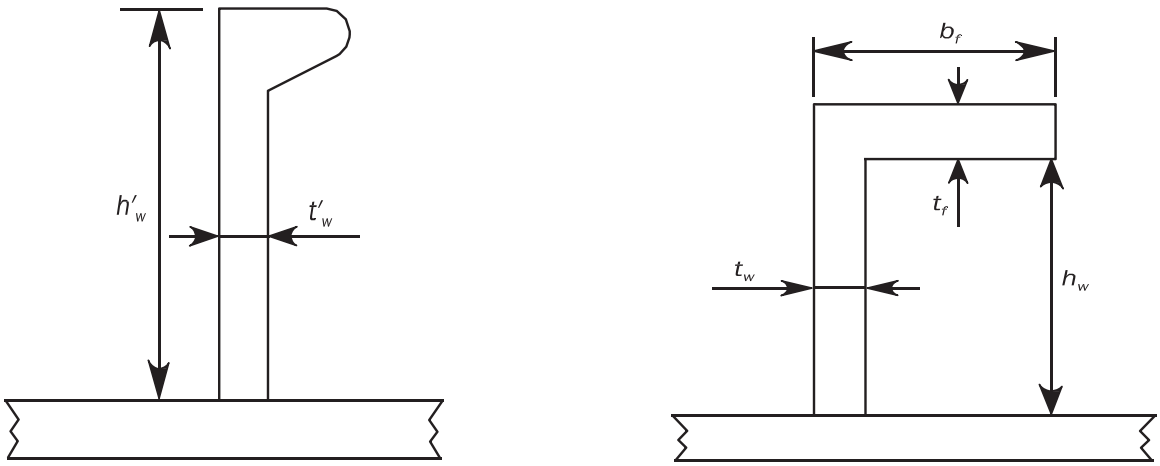

Figure 5.2.3.3 Idealisation of bulb stiffener

5.2.3.4 Ultimate buckling capacity

When $\sigma_a + \sigma_b + \sigma_w > 0$ while initially setting γ = 1, the ultimate buckling capacity for stiffeners is to be checked according to the following interaction formula:

$$\frac{\gamma_c \sigma_a + \sigma_b + \sigma_w}{R_{eH}} S = 1$$

with the corresponding buckling utilisation factor defined as:

$$\eta_{stiffener} = \frac{1}{\gamma_c}$$

where:

σ_a —— Effective axial stress, in N/mm^2, at mid span of the stiffener, acting on the stiffener with its attached plating

$$\sigma_a = \sigma_x \frac{st_p + A_s}{b_{eff1} t_p + A_s} \quad .$$

σ_x —— Nominal axial stress, in N/mm^2, acting on the stiffener with its attached plating:

(1) For FE analysis, σ_x is the FE corrected stress as defined in [5.2.3.6] in the attached plating in the direction of the stiffener axis;

(2) For prescriptive assessment, σ_x is the axial stress, in N/mm^2, calculated according to Section 3, [3.2.2.1] at load calculation point of the stiffener, as defined in Section 3, [3.1.2.1];

(3) For grillage beam analysis, σ_x is the stress acting along the *x*-axis of the attached buckling panel.

R_{eH} —— Specified minimum yield stress of the material, in N/mm^2:

(1) $R_{eH} = R_{eH_S}$ for stiffener induced failure *(SI)*;

(2) $R_{eH} = R_{eH_P}$ for plate induced failure *(PI)*.

σ_b —— Bending stress in the stiffeners, in N/mm^2:

$\sigma_b = \frac{M_0 + M_1 + M_2}{1000Z}$.

Z —— Net section modulus of stiffener, including effective width of attached plating according to [5.2.3.5], to be taken as:

(1) The section modulus calculated at the top of stiffener flange for stiffener induced failure *(SI)*;

(2) The section modulus calculated at the bottom of attached plating for plate induced failure *(PI)*.

M_2 —— Bending moment, in N·mm, due to eccentricity of sniped stiffeners, to be taken as:

(1) $M_2 = 0$ for continuous stiffeners;

(2) $M_2 = C_{snip} w_{na} \gamma \sigma_x (A_p + A_s)$ for stiffeners sniped at one or both ends.

C_{snip} —— Coefficient to account for the end effect of the stiffener sniped at one or both ends, to be taken as:

(1) $C_{snip} = -1.2$ for stiffener induced failure *(SI)*;

(2) $C_{snip} = 1.2$ for plate induced failure (*PI*).

σ_w —— Stress due to torsion, in N/mm^2, as defined in [5.4.4.4].

M_1 —— Bending moment, in N·mm, due to the lateral load, *P,* taken as follows:

(1) $M_1 = C_i \frac{|P|sl^2}{24\times10^3}$ for continuous stiffener;

(2) $M_1 = C_i \frac{|P|sl^2}{8\times10^3}$ for sniped stiffener at both ends;

(3) $M_1 = C_i \frac{|P|sl^2}{14.2\times10^3}$ for stiffener sniped at one end and continuous at the other end.

P —— Lateral load, in kN/m^2:

(1) For FE analysis， P is the average pressure as defined in Section 4, [4.2.5.2] in the attached plating;

(2) For prescriptive assessment, P is the static pressure calculated at load calculation point of the stiffener, as defined in Section 3, [3.1.2.1].

C_i —— Pressure coefficient:

(1) $C_i = C_{SI}$ for stiffener induced failure (*SI);*

(2) $C_i = C_{PI}$ for plate induced failure (*PI).*

C_{PI} —— Plate induced failure pressure coefficient:

(1) $C_{PI} = 1$ if the lateral pressure is applied on the side opposite to the stiffener;

(2) $C_{PI} = -1$ if the lateral pressure is applied on the same side as the stiffener.

C_{SI} —— Stiffener induced failure pressure coefficient:

(1) $C_{SI} = -1$ if the lateral pressure is applied on the side opposite to the stiffener;

(2) $C_{SI} = 1$ if the lateral pressure is applied on the same side as the stiffener.

M_0 —— Bending moment, in Nmm, due to the lateral deformation *w* of stiffener:

$$M_0 = F_E C_{sl} \frac{\gamma}{\gamma_{GEB}-\gamma} w_0 \text{ with precondition } \gamma_{GEB} - \gamma > 0.$$

γ_{GEB} —— Stress multiplier factor of global elastic buckling capacity as defined in [5.2.1].

F_E —— Ideal elastic buckling force of the stiffener, in N:

$$F_E = \left(\frac{\pi}{l}\right)^2 EI \times 10^4.$$

I —— Moment of inertia, in cm^4, of the stiffener including effective width of attached plating. *I* is to comply with the following requirement:

$$I \geq \frac{st_p^3}{12\times10^4}.$$

t_p (1) —— Net thickness of plate, in mm, to be taken as:

(2) For prescriptive requirements: the mean thickness of the two attached plating panels;

(3) For FE analysis, the thickness of the considered EPP on one side of the stiffener.

C_{sl} —— Deformation reduction factor to account for global slenderness, to be taken as:

(1) $C_{sl} = 1 - \frac{1}{12}\lambda_G^4$ for $\lambda_G \leq 1.56$;

(2) $C_{sl} = 3/\lambda_G^4$ for $\lambda_G > 1.56$.

λ_G —— The reference degree of global slenderness of the stiffened panel, to be taken as:

$$\lambda_G = \sqrt{\frac{\gamma_{ReH}}{\gamma_{GEB}}}$$

where: $\gamma_{ReH} = \frac{\text{Min}\,(R_{eH_P},\ R_{eH_S})}{\sqrt{\sigma_{x,av}^2+\sigma_y^2-\sigma_{x,av}\sigma_y+3\tau^2}}$.

$\sigma_{x,av}$ —— Average stress for both plate and stiffener as defined in [5.2.1.2].

σ_y —— Applied transverse stress to the plate panel as defined in [5.2.1.1].

τ —— Applied shear stress to the plate panel as defined in [5.2.1.1].

w_0 —— Assumed imperfection, in mm, to be taken as:

$$w_0 = l/1000;$$

σ_w —— Stress due to torsional deformation, in N/mm^2, to be taken as:

(1) For stiffener induce failure (*SI)*

① For $\sigma_a > 0$:

$$\sigma_w = Ey_w e_f \Phi_0 \left(\frac{m_{tor}\pi}{l_{tor}}\right)^2 \left(\frac{1}{1-\frac{\gamma\sigma_a}{\sigma_{ET}}} - 1\right) \text{ with precondition } \sigma_{ET} - \gamma\sigma_a > 0$$

② For $\sigma_a \leq 0$:

$$\sigma_w = 0$$

(2) For plate induced failure (*PI)*

$$\sigma_w = 0$$

y_w —— Distance, in mm, from centroid of stiffener cross section to the free edge of stiffener flange, to be taken as:

(1) $y_w = \frac{t_w}{2}$ for flat bar;

(2) $y_w = b_f - \frac{h_w t_w^2 + t_f b_f^2}{2A_s}$ for angle and bulb profiles;

(3) $y_w = b_{f-out} + 0.5t_w - \frac{h_w t_w^2 + t_f(b_f^2 - 2b_f d_f)}{2A_s}$ for L2 profile;

(4) $y_w = \frac{b_f}{2}$ for T profile.

Φ_0 —— Coefficient taken as:

$$\Phi_0 = \frac{l_{tor}}{m_{tor} h_w} \times 10^{-4}.$$

σ_{ET} —— Reference stress for torsional buckling, in N/mm^2, to be taken as:

$$\sigma_{ET} = \frac{E}{I_p}\left[\left(\frac{m_{tor}\pi}{l_{tor}}\right)^2 I_\omega \times 10^2 + \frac{1}{2(1+\nu)} I_T + \left(\frac{l_{tor}}{m_{tor}\pi}\right)^2 \varepsilon \times 10^{-4}\right].$$

I_p —— Net polar moment of inertia of the stiffener defined in Table 5.4.4.4, in cm^4, about point *C* as shown in Section 1 Figure 1.2.3.2, as defined in Table 5.2.3.4.

I_T —— Net St. Venant's moment of inertia of the stiffener, in cm^4, as defined in Table 5.2.3.4.

I_ω —— Net sectional moment of inertia of the stiffener, in cm^6, about point *C* as shown in Section 1, Figure 1.2.3.2(1), as shown in Table 5.2.3.4.

l_{tor} —— Stiffener span, in mm, distance equal to spacing between primary supporting members, i.e. $l_{tor} = l$. When the stiffener is supported by tripping brackets, l_{tor} is to be taken as the maximum spacing between the adjacent primary supporting members and fitted tripping brackets.

m_{tor} —— Number of half waves, taken as a positive integer so as to give smallest reference stress for torsional buckling.

ε —— Degree of fixation, to be taken as:

$\varepsilon = \left(\frac{3b}{t_p^3} + \frac{2h_w}{t_w^3}\right)^{-1}$ for bulb, angle, L2 and T profiles;

$\varepsilon = \left(\frac{t_p^3}{3b}\right)$ for flat bars.

A_w —— Net web area, in mm^2;

A_f —— Net flange area, in mm^2.

Moment of inertia Table 5.2.3.4

Cross section characteristics	**Flat bars**	**Bulb, angle, L2 and T profiles**
I_p	$\frac{h_w^3 t_w}{3 \times 10^4}$	$\left(\frac{A_w(e_f - 0.5t_f)^2}{3} + A_f e_f^2\right) \times 10^{-4}$
I_T	$\frac{h_w t_w^3}{3 \times 10^4}\left(1 - 0.63\frac{t_w}{h_w}\right)$	

		$\frac{(e_f - 0.5t_f)t_w^3}{3 \times 10^4}\left(1 - 0.63\frac{t_w}{e_f - 0.5t_f}\right) + \frac{b_f t_f^3}{3 \times 10^4}\left(1 - 0.63\frac{t_f}{b_f}\right)$
I_ω	$\frac{h_w^3 t_w^3}{36 \times 10^6}$	For bulb, angle and L2 profiles: $\frac{A_f^3 + A_w^3}{36 \times 10^6} + \frac{e_f^2}{10^6}\left(\frac{A_f b_f^2 + A_w t_w^2}{3} - \frac{(A_f b_f + A_w t_w)^2}{4(A_f + A_w)}\right)$ For T profile: $\frac{b_f^3 t_f e_f^3}{12 \times 10^6}$
Notes: (1) t_w is the net web thickness, in mm. t_{w_red} as defined in [5.2.3.2] is not to be used in this Table; (2) d_f is to be taken as 0 for bulb and angle profiles.		

5.2.3.5 Effective width of attached plating

The effective width of attached plating of stiffeners, b_{eff} in mm, is to be taken as:

(1) For $\sigma_x > 0$:

① For FE analysis,

$$b_{eff} = Min\,(C_x b, \chi_s s)$$

② For prescriptive assessment,

$$b_{eff} = Min\left(\frac{C_{x1} b_1 + C_{x2} b_2}{2}, \chi_s s\right)$$

(2) For $\sigma_x \leq 0$:

$$b_{eff} = \chi_s s$$

where: χ_s —— Effective width coefficient to be taken as:

① $\chi_s = \frac{1.12}{1 + \frac{1.75}{\left(\frac{\ell_{eff}}{s}\right)^{1.6}}} \leq 1.0$ for $\frac{\ell_{eff}}{s} \geq 1$

② $\chi_s = 0.407\frac{\ell_{eff}}{s}$ for $\frac{\ell_{eff}}{s} < 1.$

ℓ_{eff}____ Effective length of the stiffener, in mm, taken as:

(1) $\ell_{eff} = \frac{l}{\sqrt{3}}$ for stiffener fixed at both ends;

(2) $\ell_{eff} = 0.75l$ for stiffener simply supported at one end and fixed a the other.

(3) $\ell_{eff} = l$ for stiffener simply supported at both ends.

5.2.3.6 FE corrected stresses for stiffener capacity

When the reference stresses σ_x and σ_y obtained by FE analysis according to Section 4, [4.2.4] are both compressive, σ_x is to be corrected according to the following formulae:

(1) If $\sigma_x < \nu\sigma_y$

$$\sigma_{xcor} = 0$$

(2) If $\sigma_x \geq \nu\sigma_y$

$$\sigma_{xcor} = \sigma_x - \nu\sigma_y$$

5.2.4 Primary Supporting Members

5.2.4.1 Web plate in way of openings

The web plate of primary supporting members with openings is to be assessed for buckling based on the combined axial compressive and shear stresses.

The web plate adjacent to the opening on both sides is to be considered as individual unstiffened plate panels as shown in Table 5.2.4.1.

The interaction formulae of [5.2.2.1] are to be used with:

$$\sigma_x = \sigma_{av}$$

$$\sigma_y = 0$$

$$\tau = \tau_{av}$$

where: σ_{av} —— Weighted average compressive stress, in N/mm^2, in the area of web plate being considered, i.e. *P1, P2* and *P3* as shown in Table 5.2.4.1.

For the application of Table 5.2.4.1, the weighted average shear stress is to be taken as:

(1) Opening modelled in primary supporting members:

τ_{av} —— Weighted average compressive stress, in N/mm^2, in the area of web plate being considered, i.e. *P1, P2* and *P3* as shown in Table 5.2.4.1.

(2) Opening not modelled in primary supporting members:

τ_{av} —— Weighted average shear stress, in N/mm^2, given in Table 5.2.4.1.

Buckling reduction factors of web plate in way of openings Table 5.2.4.1

Configuration (1)		C_x, C_y	C_τ	
			Opening modelled in PSM	**Opening not modelled in PSM**
(a) Without edge reinforcements (2)		Separate reduction factors are to be applied to areas *P1* and *P2* using case ③ or case ⑥ in Table 5.2.2.3, with edge stress ratio: ψ＝1.0	Separate reduction factors are to be applied to areas *P1* and *P2* using case ⑱ or case ⑲ in Table 5.2.2.3.	When case ⑰ of Table 5.2.2.3 is applicable: A common reduction factor is to be applied to areas *P1* and *P2* using case ⑰ with: $\tau_{av} = \tau_{av}(web)$; When case ⑰ of Table 5.2.2.3 is not applicable: Separate reduction factors are to be applied to areas *P1* and *P2* using case ⑱ or case ⑲ with: $\tau_{av} = \tau_{av}(web)h/(h - h_0)$
(b) With edge reinforcement		Separate reduction factors are to be applied for areas *P1* and *P2* using C_x for case ① or C_y for case ② in Table 5.2.2.3 with stress ratio: ψ＝1.0.	Separate reduction factors are to be applied for areas *P1* and *P2* using case ⑮ in Table 5.2.2.3.	Separate reduction factors are to be applied to areas *P1* and *P2* using case ⑮ in Table 5.2.2.3 with: $\tau_{av} = \tau_{av}(web)h/(h - h_0)$
(c) Example of hole in web			Panels *P1* and *P2* are to be evaluated in accordance with (a). Panel *P3* is to be evaluated in accordance with (b).	

where:

h —— Height, in m, of the web of the primary supporting member in way of the opening;

h_0 —— Height, in m, of the opening measured in the depth of the web;

$\tau_{av}(web)$ —— Weighted average shear stress, in N/mm^2, over the web height of the primary supporting

Configuration (1)	C_x, C_y	C_τ	
		Opening modelled in PSM	Opening not modelled in PSM
member. Note (1) Web panels to be considered for buckling in way of openings are shown shaded and numbered *P1*, *P2*, etc. Note (2) For a PSM web panel with opening and without edge reinforcements as shown in configuration (a), the applicable buckling assessment method depends on its specific boundary conditions. If one of the long edges along the face plate or along the attached plating is not subject to "inline support", i.e. the edge is free to pull in, Method B should be applied. In other cases, typically such as when the short plate edge is attached to the plate flanges, Method A is applicable.			

5.2.4.2 Reduction factors of web plate in way of openings

The reduction factors, C_x or C_y in combnaiton with C_τ of the plate panel(s) of the web adjacent to the opening is to be taken as shown in Table 5.2.4.1.

5.2.4.3 The equivalent plate panel of web plate of primary supporting members crossed by perpendicular stiffeners is to be idealised as shown in Figure 5.2.4.3.

The correction of panel breadth is applicable also for other slot configurations provided that the web or collar plate is attached to at least one side of the passing stiffener.

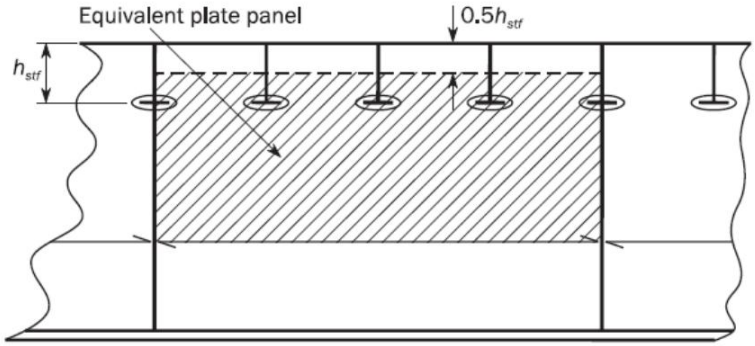

Figure 5.2.4.3 PMS web plate idealisation

5.2.5 Stiffened Panels with U-type Stiffeners

5.2.5.1 Local plate buckling

For stiffened panels with U-type stiffeners, local plate buckling is to be checked for each of the plate panels EPP b_1, b_2, b_f and h_w (see Section 1, Figure 1.2.3.2(2)) separately as follows:

(1) The attached plate panels EPP b_1, b_2 are to be assessed using SP-A model, where in the calculation of buckling factors K_x as defined in Case ① of Table 5.2.2.3, the correction factor F_{long} for U-type stiffeners as defined in Table 5.2.2.4 is to be used; and in the calculation of K_y as defined in Case ② of Table, the F_{tran} for U-type stiffeners as defined in [5.2.2.5] is to be used.

(2) The face plate and web plate panels EPP b_f and h_w are to be assessed using UP-B model with $F_{long} = 1$ and $F_{tran} = 1$.

5.2.5.2 Overall stiffened panel buckling and stiffener buckling

For a stiffened panel with U-type stiffeners, the overall buckling capacity and ultimate capacity of the stiffeners are to be checked with warping stress σ_w = 0, and with bending moment of inertia including effective width of attached plating being calculated based on the following assumptions:

(1) The two web panels of a U-type stiffener are to be taken as perpendicular to the attached plate with thickness equal to t_w and height equal to the distance between the attached plate and the face plate of the stiffener.

(2) Effective width of the attached plating b_{eff}, taken as the sum of the b_{eff} calculated for EPP, b_1 and b_2 respectively according to SP-A model.

(3) Effective width of the attached plating of a stiffener without shear lag effect, b_{eff1}, taken as the sum of the b_{eff1} calculated for the EPP, b_1 and b_2 respectively.

5.3 Buckling capacity of column structures

5.3.1 Column Buckling of Corrugations

5.3.1.1 Buckling utilisation factor

The column buckling utilisation factor, η, for axially compressed corrugations is to be taken as:

$$\eta_{column} = \frac{\sigma_{av}}{\sigma_{cr}}$$

where: σ_{av} —— Average axial compressive stress in the member, in N/mm^2;

σ_{cr} —— Minimum critical buckling stress, in N/mm^2, taken as:

① $\sigma_{cr} = \sigma_E$ for $\sigma_E \leq 0.5R_{eH_S}$

② $\sigma_{cr} = \left(1 - \frac{R_{eH_S}}{4\sigma_E}\right) R_{eH_S}$ for $\sigma_E > 0.5R_{eH_S}$;

σ_E —— Elastic column compressive buckling stress, in N/mm^2, according to [5.3.1.2];

R_{eH_S} —— Specified minimum yield stress of the considered member, in N/mm^2. For built-up members, the lowest specified minimum yield stress is to be used.

5.3.1.2 Elastic column buckling stress

The elastic compressive column buckling stress, σ_E, in N/mm^2 of members subject to axial compression is to be taken as:

$$\sigma_E = \pi^2 E f_{end} \frac{I}{A l_{pill}^2} \times 10^{-4}$$

where: I —— Net moment of inertia about the weakest axis of the cross section, in cm^4;

A —— Net cross-sectional area of the member, in cm^2;

l_{pill} —— Unsupported length of the member, in m;

f_{end} —— End constraint factor, corresponding to simply supported ends is to be applied except for fixed end support to be used in way of stool with width exceeding 2 times the depth of the corrugation, taken as:

- $f_{end} = 1.0$ where both ends are simply supported;
- $f_{end} = 2.0$ where one end is simply supported and the other end is fixed;
- $f_{end} = 4.0$ where both ends are fixed.

SECTION 6 STRESS BASED REFERENCE STRESSES

Symbols

a —— Length, in mm, of the longer side of the plate panel as defined in Section 5;

b —— Length, in mm, of the shorter side of the plate panel as defined in Section 5;

A_i —— Area, in mm^2, of the i-th plate element of the buckling panel;

n —— Number of plate elements in the buckling panel;

σ_{xi} —— Actual stress, in N/mm^2, at the centroid of the *i*-th plate element in *x* direction, applied along the shorter edge of the buckling panel;

σ_{yi} —— Actual stress, in N/mm^2, at the centroid of the *i*-th plate element in *y* direction, applied along the longer edge of the buckling panel;

ψ —— Edge stress ratio as defined in Section 5;

τ_i —— Actual membrane shear stress, in N/mm^2, at the centroid of the *i*-th plate element of the buckling panel.

6.1 Stress Based Method

6.1.1 Introduction

6.1.1.1 This Section provides a method to determine stress distribution along edges of the considered buckling panel by second-order polynomial curve, by linear distribution using least square method and by weighted average approach. The reference stress is the stress components at centre of plate element transferred into the local system of the considered buckling panel.

6.1.1.2 Definition

A regular panel is a plate panel of rectangular shape. An irregular panel is plate panel which is not regular, as detailed in Section 4, [4.2.3.1].

6.1.2 Stress Application

6.1.2.1 Regular panel

The reference stresses are to be taken as defined in [6.2.1] for a regular panel when the following conditions are satisfied:

- At least, one plate element centre is located in each third part of the long edge *a* of a regular panel; and
- This element center is located at a distance in the panel local *x* direction not less than *a*/4 to at least one of the element centers in the adjacent third part of the panel.

Otherwise, the reference stresses are to be taken as defined in [6.2.2] for an irregular panel.

6.1.2.2 Irregular panel and curved panel

The reference stresses of an irregular panel or of a curved panel are to be taken as defined in [6.2.2].

6.2 Reference Stresses

6.2.1 Regular Panel

6.2.1.1 Longitudinal stress

The longitudinal stress σ_x applied on the shorter edge of the buckling panel is to be calculated as follows:

For plate buckling assessment, the distribution of $\sigma_x(x)$ is assumed as second order polynomial curve as:

$$\sigma_x = Cx^2 + Dx + E$$

The best fitting curve $\sigma_x(x)$ is to be obtained by minimising the square error Π considering the area of each element as a weighting factor:

$$\Pi = \sum_{i=1}^{n} A_i\left[\sigma_{xi} - (Cx_i^2 + Dx_i + E)\right]^2$$

The unknown coefficients *C*, *D* and *E* is yield zero first derivatives, $\partial\Pi$ with respect to *C, D* and *E,* respectively.

$$\begin{cases} \dfrac{\partial\Pi}{\partial C} = 2\displaystyle\sum_{i=1}^{n} A_i x_i^2\left[\sigma_{xi} - \left(Cx_i^2 + Dx_i + E\right)\right] = 0 \\ \dfrac{\partial\Pi}{\partial D} = 2\displaystyle\sum_{i=1}^{n} A_i x_i\left[\sigma_{xi} - \left(Cx_i^2 + Dx_i + E\right)\right] = 0 \\ \dfrac{\partial\Pi}{\partial E} = 2\displaystyle\sum_{i=1}^{n} A_i\left[\sigma_{xi} - \left(Cx_i^2 + Dx_i + E\right)\right] = 0 \end{cases}$$

The unknown coefficients *C, D* and *E* can be obtained by solving the 3 above equations.

$$\sigma_{x1} = \frac{1}{b}\int_0^b \sigma_x(x)dx = \frac{b^2}{3}C + \frac{b}{2}D + E$$

$$\sigma_{x2} = \frac{1}{b}\int_{a-b}^{a} \sigma_x(x)dx = \left(a^2 - ab + \frac{b^2}{3}\right)C + \left(a - \frac{b}{2}\right)D + E$$

If $-\frac{D}{2C} < \frac{b}{2}$ or $-\frac{D}{2C} > a - \frac{b}{2}$, , σ_{x3} is to be ignored. Otherwise, σ_{x3} is taken as:

$$\sigma_{x3} = \frac{1}{b}\int_{x_{min}}^{x_{max}} \sigma_x(x)dx = \frac{b^2}{12}C - \frac{D^2}{4C} + E$$

where: $x_{min} = -\frac{b}{2} - \frac{D}{2C}$

$$x_{max} = \frac{b}{2} - \frac{D}{2C}$$

The longitudinal stress is to be taken as:

$$\sigma_x = Max\left(\sigma_{x1}, \sigma_{x2}, \sigma_{x3}\right) \ ;$$

The edge stress ratio is to be taken as:

$$\psi_x = 1$$

For overall stiffened panel buckling and stiffener buckling assessments, the longitudinal stress σ_x applied on the shorter edge of the attached plate is to be taken as:

$$\sigma_x = \frac{\sum_{i=1}^{n} A_i\sigma_{xi}}{\sum_{i=1}^{n} A_i}$$

The edge stress ratio ψ_x for the stress σ_x is equal to 1.0.

6.2.1.2 Transverse stress

The transverse stress σ_y applied along the longer edges of the buckling panel is to be calculated by extrapolation of the transverse stresses of all elements up to the shorter edges of the considered buckling panel.

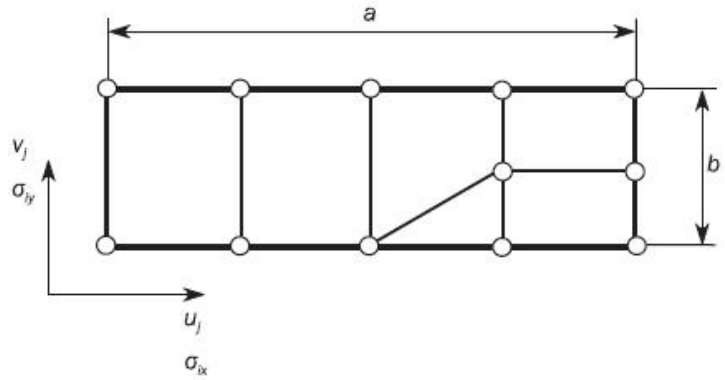

Figure 6.2.1.2 Buckling panel

The distribution of $\sigma_y(x)$ is assumed as straight line. Therefore:

$$\sigma_y(x) = A + Bx$$

The best fitting curve $\sigma_y(x)$ is to be obtained by the least square method minimising the square error Π considering area of each element as a weighting factor.

$$\Pi = \sum_{i=1}^{n} A_i\left[\sigma_{yi} - (A + Bx_i)\right]^2$$

The unknown coefficients A and B are to yield zero first partial derivatives, $\partial\Pi$ with respect to A and B, respectively.

$$\frac{\partial\Pi}{\partial A} = 2\sum_{i=1}^{n} A_i\left[\sigma_{yi} - (A + Bx_i)\right] = 0$$

$$\frac{\partial\Pi}{\partial B} = 2\sum_{i=1}^{n} A_i x_i\left[\sigma_{yi} - (A + Bx_i)\right] = 0$$

The unknown coefficients A and B are obtained by solving the 2 above equations and are given as follow:

$$A = \frac{\left(\sum_{i=1}^{n} A_i\sigma_{yi}\right)\left(\sum_{i=1}^{n} A_i x_i^2\right) - \left(\sum_{i=1}^{n} A_i x_i\right)\left(\sum_{i=1}^{n} A_i x_i\sigma_{yi}\right)}{\left(\sum_{i=1}^{n} A_i\right)\left(\sum_{i=1}^{n} A_i x_i^2\right) - \left(\sum_{i=1}^{n} A_i x_i\right)^2}$$

$$B = \frac{\left(\sum_{i=1}^{n} A_i\right)\left(\sum_{i=1}^{n} A_i x_i\sigma_{yi}\right) - \left(\sum_{i=1}^{n} A_i x_i\right)\left(\sum_{i=1}^{n} A_i\sigma_{yi}\right)}{\left(\sum_{i=1}^{n} A_i\right)\left(\sum_{i=1}^{n} A_i x_i^2\right) - \left(\sum_{i=1}^{n} A_i x_i\right)^2}$$

The transverse stress is to be taken as:

$$\sigma_y = max\,(A, A + Ba)$$

The edge stress ratio is to be taken as:

$$\psi_y = \frac{min\,(A, A + Ba)}{max\,(A, A + Ba)} \text{ for } \sigma_y > 0$$

$$\psi_y = 1 \text{ for } \sigma_y \leq 0.$$

6.2.1.3 Shear stress

The shear stress τ is to be calculated using a weighted average approach, and is to be taken as:

$$\tau = \frac{\sum_{i=1}^{n} A_i\tau_i}{\sum_{i=1}^{n} A_i}$$

6.2.2 Irregular Panel and Curved Panel

6.2.2.1 Reference stresses

The longitudinal, transverse and shear stresses are to be calculated using a weighted average approach. They are to be taken as:

$$\sigma_x = \frac{\sum_{i=1}^{n} A_i \sigma_{xi}}{\sum_{i=1}^{n} A_i}$$

$$\sigma_y = \frac{\sum_{i=1}^{n} A_i \sigma_{yi}}{\sum_{i=1}^{n} A_i}$$

$$\tau = \frac{\sum_{i=1}^{n} A_i \tau_i}{\sum_{i=1}^{n} A_i}$$

The edge stress ratios are to be taken as:

$$\psi_x = 1;$$

$$\psi_y = 1.$$

CHAPTER 3 EQUIPMENT AND OUTFITS

Section 1 RUDDERS

3.1.1 General requirements

3.1.1.1 Basic assumptions

(1) This Section applies to ordinary profile rudders, and to some enhanced profile rudders with special arrangements for increasing the rudder force. Rudders not conforming to the profile types included in this Section will be subject to special consideration.

(2) This section applies to rudders made of steel. Rudders made of material different from steel will be subject to special consideration.

3.1.1.2 Design considerations

(1) Effective means are to be provided for supporting the weight of the rudder without excessive bearing pressure, e.g. by a rudder carrier attached to the upper part of the rudder stock. The hull structure in way of the rudder carrier is to be suitably strengthened.

(2) Suitable arrangements are to be provided to prevent the rudder from lifting.

(3) In rudder trunks which are open to the sea, a seal or stuffing box is to be fitted above the deepest load waterline, to prevent water from entering the steering gear compartment and the lubricant from being washed away from the rudder carrier. If the top of the rudder trunk is below the waterline at scantling draught (without trim), two separate watertight seals/stuffing boxes are to be provided.

3.1.1.3 Materials

(1) Welded parts of rudders are to be made of materials complying with relevant requirements for hull structural steel in CCS Rules for Materials and Welding.

(2) Material factor k for normal and high tensile steel plating may be taken into account when specified in each individual rule requirement. The material factor k is to be taken as defined in Section 3, Chapter 1 of this PART, unless otherwise specified.

(3) Steel grade of plating materials for rudders and rudder horns are to be in accordance with Section 3, Chapter 1 of this PART.

(4) Rudder stocks, pintles, coupling bolts, keys and cast parts of rudders are to be made of rolled, forged or cast carbon manganese steel in accordance with CCS Rules for Materials and Welding.

(5) For rudder stocks, pintles, keys and bolts the minimum yield stress is not to be less than 200 N/mm^2. The requirements of this Section are based on a material's yield stress of 235 N/mm^2. If material is used having a yield stress differing from 235 N/mm^2 the material factor K is to be determined as follows:

$$K=\left(\frac{235}{R_{eH}}\right)^{e}$$

where: e = 0.75 for $R_{eH} > 235$ N/mm^2;

e = 1.00 for $R_{eH} \leq 235$ N/mm^2;

R_{eH} —specified minimum yield stress (N/mm^2) of material used, and is not to be taken greater than $0.7R_m$ or 450 N/mm^2, whichever is the smaller value;

R_m — tensile strength (N/mm^2) of material used.

3.1.1.4 Welding and design details

(1) Slot-welding is to be limited as far as possible. Slot welding is not to be used in areas with large in-plane stresses transversely to the slots or in way of cut-out areas of semi-spade rudders.

When slot welding is applied, the length of slots is to be minimum 75 mm with breadth of 2t, where t is the rudder plate thickness, in mm. The distance between ends of slots is not to be more than 125 mm. The fillet leg length is to comply with calculation requirements in 1.4.4, Chapter 1 of this PART, and welding is to be based on a weld factor of 0.44. The slots are to be fillet welded around the edges and filled with a suitable compound, e.g. epoxy putty. Slots are not to be filled with weld.

Continuous slot welds are to be used in lieu of slot welds. When continuous slot welding is applied, the root gap is to be between 6-10 mm. The bevel angle is to be at least 15°.

(2) In way of the rudder horn recess of semi-spade rudders, the radii in the rudder plating except in way of solid part in cast steel are not to be less than 5 times the plate thickness, but in no case less than 100 mm. Welding in side plate is to be avoided in or at the end of the radii. Edges of side plate and weld adjacent to radii are to be ground smooth.

(3) Welds in the rudder side plating subjected to significant stresses from rudder bending and welds between plates and heavy pieces (solid parts in forged or cast steel or very thick plating) are to be made as

full penetration welds. In way of highly stressed areas e.g. cut-out of semi-spade rudder and upper part of spade rudder, cast or welding on ribs is to be arranged. Two sided full penetration welding is normally to be arranged. Where back welding is impossible welding is to be performed against ceramic backing bars or equivalent. Steel backing bars may be used and are to be continuously welded on one side to the bevelled edge, see Figure 3.1.1.4(3). The bevel angle is to be at least 15° for one sided welding.

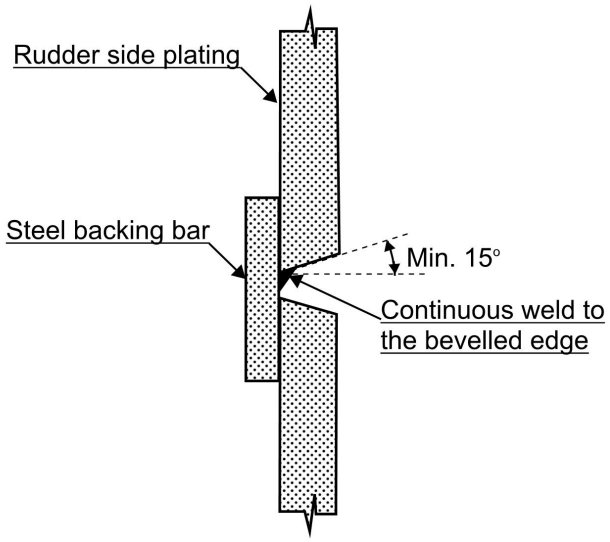

Figure 3.1.1.4(3) Use of steel backing bar in way of full penetration welding of rudder side plating

(4) Requirements for welding and design details of rudder trunks are described in 3.1.9.2 of this Section.
(5) Requirements for welding and design details when the rudder stock is connected to the rudder by horizontal flange coupling are described in 3.1.6.1(4) of this Section.
(6) Requirements for welding and design details of rudder horns are described in 3.1.9.1(3).

3.1.1.5 Equivalence

(1) CCS may accept alternatives to requirements given in this Section, provided they are deemed to be equivalent.
(2) Direct analyses adopted to justify an alternative design are to take into consideration all relevant modes of failure, on a case by case basis. These failure modes may include, amongst others: yielding, fatigue, buckling and fracture. Possible damages caused by cavitation are also to be considered.
(3) Where deemed necessary by CCS, lab tests, or full scale tests may be requested to validate the alternative design approach.

3.1.2 Rudder force and rudder torque

3.1.2.1 Rudder blades without cut-outs

(1) The rudder force C_R upon which the rudder scantlings are to be based is to be determined from the following formula:

$$C_R = 132 K_1 K_2 K_3 A V^2 \quad \text{N}$$

where: C_R — rudder force, in N;
A — area of rudder blade, in m^2;
V — maximum service speed (knots). When the speed is less than 10 knots, V is to be replaced by the following:
$V_{min} = (V + 20) / 3$
For the astern condition the maximum astern speed V_{astern} (the greatest speed which the ship is designed to maintain in service at sea at the deepest sea-going draught) is to be used, however, in no case less than:
$V_{astern} = 0.5\ V$;
K_1 — factor depending on the aspect ratio λ of the rudder area;
$K_1 = (\lambda + 2)/3$, with λ not to be taken greater than 2;
$\lambda = b^2/A_t$;
b — mean height of the rudder area, in m. Mean breadth and mean height of rudder are calculated according to the coordinate system in Figure 3.1.2.1;
A_t — sum of rudder blade area A and area of rudder post or rudder horn, if any, within the height b, in m^2;

K_2 — coefficient depending on the type of the rudder and the rudder profile according to Table 3.1.2.1; data may be provided by tests with approval of CCS;

K_3 = 0.8 for rudders outside the propeller jet;
= 1.15 for rudders behind a fixed propeller nozzle;
= 1.0 otherwise.

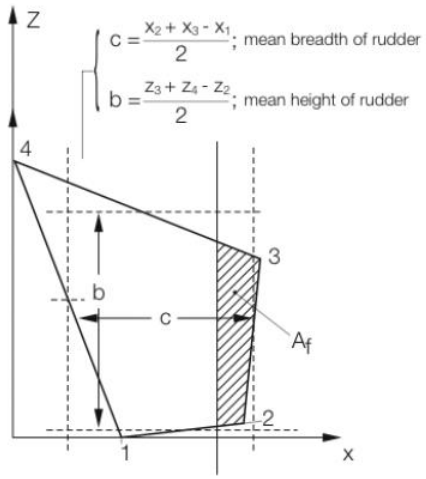

Figure 3.1.2.1

Factor K_2 **Table 3.1.2.1**

Profile Type		K_2	
		Ahead condition	Astern condition
NACA-00 series Göttingen		1.1	0.80
Flat side		1.1	0.90
Hollow		1.35	0.90
High lift rudders		1.7	1.30
Fish tail		1.4	0.8
Single plate		1.0	1.0
Mixed profiles （e.g. HSVA）		1.21	0.9

(2) The rudder torque is to be calculated for both the ahead and astern condition as follows:

$$Q_R = C_R r \quad \text{Nm}$$

where: $r = c\,(\alpha\text{-}k)$, in m;

c — mean breadth of rudder area, in m, see Figure 3.1.2.1;

α — coefficient, taken as 0.33 for ahead condition and 0.66 for astern condition; special consideration may be given for high lift rudders, and taken as 0.40 for ahead condition and 0.66 for astern condition if no test data may be provided;

$k = \frac{A_f}{A}$;

A_f — portion of the rudder blade area situated ahead of the centre line of the rudder stock, in m^2;

$r_{min} = 0.1c$, in m, for ahead condition.

3.1.2.2 Rudder blades with cut-outs (semi-spade rudders)

The total rudder force C_R is to be calculated according to 3.1.2.1(1) of this Section. The pressure distribution over the rudder area, upon which the determination of rudder torque and rudder blade strength is to be based, is to be derived as follows:

The rudder area may be divided into two rectangular or trapezoidal parts with areas A_1 and A_2, so that $A = A_1 + A_2$ (see Figure 3.1.2.2).

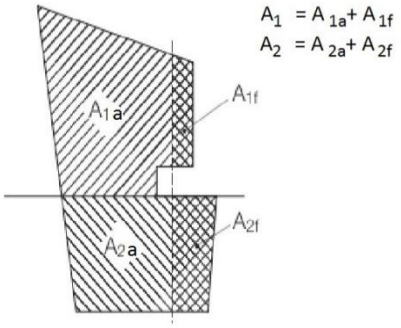

Figure 3.1.2.2 Areas A_1 and A_2

The levers r_1 and r_2 are to be determined as follows:

$$r_1 = c_1 (\alpha - k_1), \text{ m};$$

$$r_2 = c_2 (\alpha - k_2), \text{ m};$$

where: c_1, c_2 — mean breadth of partial areas A_1, A_2 determined, where applicable, in accordance with Figure 3.1.2.1;

$$k_1 = \frac{A_{1f}}{A_1};$$

$$k_2 = \frac{A_{2f}}{A_2};$$

A_{1a} —portion of A_1 situated aft of the centre line of the rudder stock, in m^2;

A_{1f} — portion of A_1 situated ahead of the centre line of the rudder stock, in m^2;

A_{2a} —portion of A_2 situated aft of the centre line of the rudder stock, in m^2;

A_{2f} — portion of A_2 situated ahead of the centre line of the rudder stock, in m^2;

α = 0.33 for ahead condition;

α = 0.66 for astern condition;

For parts of a rudder behind a fixed structure such as the rudder horn:

α = 0.25 for ahead condition;

α = 0.55 for astern condition;

The resulting force of each part may be taken as:

$$C_{R1} = C_R \frac{A_1}{A} \quad \text{N}$$

$$C_{R2} = C_R \frac{A_2}{A} \quad \text{N}$$

The resulting torque of each part may be taken as:

$$Q_{R1} = C_{R1} r_1 \quad \text{N·m}$$

$$Q_{R2} = C_{R2} r_2 \quad \text{N·m}$$

The total rudder torque is to be calculated for both the ahead and astern condition as follows:

$$Q_R = Q_{R1} + Q_{R2} \quad \text{N·m}$$

For ahead condition Q_R is not to be taken less than:

$$Q_{Rmin} = 0.1\, C_R \frac{A_1 c_1 + A_2 c_2}{A} \quad \text{N·m}$$

3.1.3 Rudder strength calculation

3.1.3.1 The rudder force and resulting rudder torque as given in 3.1.2 of this Section causes bending moments and shear forces in the rudder body, bending moments and torques in the rudder stock, supporting forces in pintle bearings and rudder stock bearings and bending moments, shear forces and torques in rudder horns and heel pieces. The rudder body is to be stiffened by horizontal and vertical webs enabling it to act as a bending girder.

3.1.3.2 The bending moments, shear forces and torques as well as the reaction forces are to be determined by a direct calculation or by an approximate simplified method considered appropriate by CCS. For rudders

supported by sole pieces or rudder horns these structures are to be included in the calculation model in order to account for the elastic support of the rudder body. Guidelines for calculation of bending moment and shear force distribution are given in Appendix 1 to this Chapter.

3.1.4 Rudder stock scantlings

3.1.4.1 The rudder stock diameter required for the transmission of the rudder torque is to be dimensioned such that the torsional stress τ_t is not exceeding the following value:

$$\tau_t = 68 / K \quad \text{N/mm}^2$$

The rudder stock diameter for the transmission of the rudder torque d_t is therefore not to be less than:

$$d_t = 4.2\sqrt[3]{Q_R K} \quad \text{mm}$$

where: Q_R — total rudder torque [N·m] as calculated in 3.1.2.1(2) and 3.1.2.2 of this Section;

K — material factor for the rudder stock as given in 3.1.1.3(5) of this Section.

3.1.4.2 Rudder stock scantlings due to combined loads

If the rudder stock is subjected to combined torque and bending, the equivalent stress in the rudder stock is not to exceed $118 / K$ N/mm^2.

K — material factor for the rudder stock as given in 3.1.1.3(5).

The equivalent stress σ_c is to be determined by the formula:

$$\sigma_c = \sqrt{\sigma_b^2 + 3\tau_t^2} \quad \text{N/mm}^2$$

where: bending stress: $\sigma_b = \dfrac{10.2M}{d_c^3} \times 10^3$ N/mm^2;

torsional stress: $\tau_t = \dfrac{5.1Q_R}{d_c^3} \times 10^3$ N/mm^2.

The rudder stock diameter d_c is therefore not to be less than:

$$d_c = d_t \sqrt[6]{1 + \frac{4}{3}\left(\frac{M}{Q_R}\right)^2} \quad \text{mm} \qquad \text{mm}$$

where: M — bending moment, in N·m, at the station of the rudder stock considered.

For a spade rudder with trunk extending inside the rudder, the rudder stock scantlings are to be checked against the two cases defined in 2.2, Appendix 1 of this Chapter.

3.1.4.3 Before significant reductions in rudder stock diameter due to the application of steels with specified minimum yield stresses exceeding 235 N/mm^2 are granted, CCS may require the evaluation of the rudder stock deformations. Large deformations of the rudder stock are to be avoided in order to avoid excessive edge pressures in way of bearings.

3.1.5 Rudder blade

3.1.5.1 Permissible stresses

The section modulus and the web area of a horizontal section of the rudder blade are to be such that the following stresses will not be exceeded:

(1) In general, except in way of rudder recess sections where (2) applies

① bending stress σ_b $110/k$ N/mm^2

② shear stress τ $50/k$ N/mm^2

③ equivalent stress $\sigma_e = \sqrt{\sigma_b^2 + 3\tau^2}$ $120/k$ N/mm^2

K — material factor for the rudder plating as given in 3.1.1.3(2).

(2) In way of the recess for the rudder horn pintle on semi-spade rudders

① bending stress σ_b 75 N/mm^2

② shear stressτ 50 N/mm^2

③ equivalent stress $\sigma_e = \sqrt{\sigma_b^2 + 3\tau^2}$ 100 N/mm^2

Note: The stresses in (2) apply equally to high tensile and ordinary steels.

3.1.5.2 Rudder plating

The thickness t of the rudder side, top and bottom plating is not to be less than:

$$t = 5.5 s \beta \sqrt{K} \sqrt{d + C_R 10^{-4} / A} + 2.5 \quad \text{mm}$$

where: d — scantling draught, in m;

C_R — rudder force, in N, according to 3.1.2.1 of this Section;

A — rudder area, in m^2;

$\beta=\sqrt{1.1-0.5(\frac{s}{b})^2}$ max. 1.00 if $\frac{b}{s} \geq 2.5$;

s — smallest unsupported width of plating, in m;

b — greatest unsupported width of plating, in m;

K — material factor for the rudder plating as given in 3.1.1.3(2).

The thickness of the nose plate of rudder blades is not to be less than 1.2 times that of rudder side plating, but need not be greater than 22 mm. The thickness of web plates is not to be less than the greater of 70% of the rudder side plating thickness and 8 mm.

The rudder plating in way of the solid part is to be of increased thickness per 3.1.5.3(4).

3.1.5.3 Connections of rudder blade structure with solid parts

(1) Solid parts in forged or cast steel, which house the rudder stock or the pintle, are to be provided with protrusions.

These protrusions are not required when the web plate thickness is less than:

-10 mm for web plates welded to the solid part on which the lower pintle of a semi-spade rudder is housed and for vertical web plates welded to the solid part of the rudder stock coupling of spade rudders;

-20 mm for other web plates.

(2) The solid parts are in general to be connected to the rudder structure by means of two horizontal web plates and two vertical web plates.

(3) Minimum section modulus of the connection with the rudder stock housing.

The section modulus of the cross-section of the structure of the rudder blade W_s, in cm^3, formed by vertical web plates and rudder plating, which is connected with the solid part where the rudder stock is housed is to be not less than:

$$W_s = c_s d_c^{\,3} \left(\frac{H_E - H_x}{H_E} \right)^2 \frac{K}{K_s} 10^{-4} \text{ cm}^3$$

where: c_s — coefficient, to be taken equal to:

= 1.0 if there is no opening in the rudder plating or if such openings are closed by a full penetration welded plate;

= 1.5 if there is an opening in the considered cross-section of the rudder;

d_c — diameter of rudder stock in way of lower bearing, in mm, calculated according to 3.1.4 of this Section;

H_E — vertical distance between the lower edge of the rudder blade and the upper edge of the solid part, in m;

H_X — vertical distance between the considered cross-section and the upper edge of the solid part, in m;

K — material factor for the rudder blade plating as given in 3.1.1.3(2);

K_s — material factor for the rudder stock as given in 3.1.1.3(5).

The actual section modulus of the cross-section of the structure of the rudder blade is to be calculated with respect to the symmetrical axis of the rudder. The breadth of the rudder plating, in m, to be considered for the calculation of section modulus is to be not greater than:

$$b = s_v + 2H_X / 3 \quad \text{m}$$

where: s_v — spacing between the two vertical webs, in m (see Figure 3.1.5.3).

Where openings for access to the rudder stock nut are not closed by a full penetration welded plate, they are to be deducted.

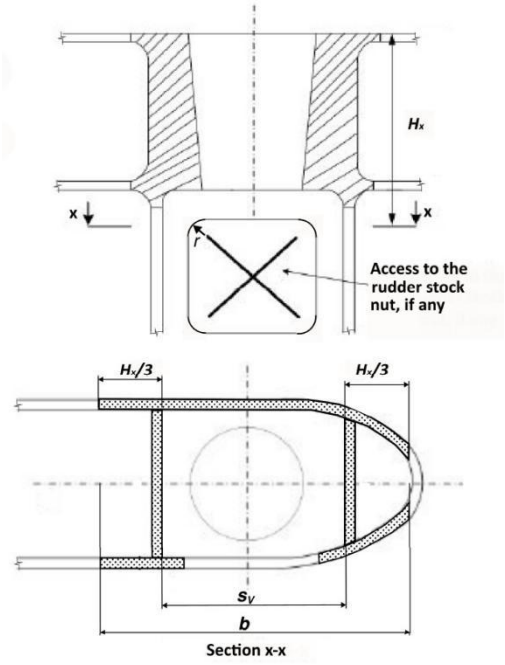

Figure 3.1.5.3 Cross-section of the connection between rudder blade structure and rudder stock housing, example with opening in only one side shown

(4) The thickness of the horizontal web plates connected to the solid parts, in mm, as well as that of the rudder blade plating between these webs, is to be not less than the greater of the following values:

$$t_H = 1.2t \quad \text{mm}$$

$$t_H = 0.045 d_s^{\,2} / S_H \quad \text{mm}$$

where: t— defined in 3.1.5.2 of this Section;

d_S — diameter, in mm, to be taken equal to:

= d_c, as per 3.1.4.2 of this Section, for the solid part housing the rudder stock;

=d_p, as per 3.1.7.1 of this Section, for the solid part housing the pintle;

S_H — spacing between the two horizontal web plates, in mm.

The increased thickness of the horizontal webs is to extend fore and aft of the solid part at least to the next vertical web.

(5) The thickness of the vertical web plates welded to the solid part where the rudder stock is housed as well as the thickness of the rudder side plating under this solid part is to be not less than the values obtained, in mm, from Table 3.1.5.3.

Thickness of side plating and vertical web plates Table 3.1.5.3

Type of rudder	Thickness of vertical web plates, in mm		Thickness of rudder plating, in mm	
	Rudder blade without opening	Rudder blade with opening	Rudder blade without opening	Area with opening
Rudder supported by sole piece	1.2 t	1.6 t	1.2 t	1.4 t
Semi-spade and spade rudders	1.4 t	2.0 t	1.3 t	1.6 t

where: t = thickness of the rudder plating, in mm, as defined in 3.1.5.2 of this Section.

The vertical web plates and rudder plating the thickness of which has been increased are to extend below the solid piece at least to the next horizontal web.

3.1.5.4 Single plate rudders

(1) Mainpiece diameter

The mainpiece diameter is calculated according to 3.1.4.1 and 3.1.4.2 of this Section respectively. For spade rudders the lower third may taper down to 0.75 times stock diameter.

(2) Blade thickness

The blade thickness t is not to be less than:

$$t_b = 1.5 s V \sqrt{K} + 2.5 \quad \text{mm}$$

where: s — spacing of stiffening arms, in m not to exceed 1 m;

V — speed in knots, see 3.1.2.1(1) of this Section;

K — material factor for the rudder plating as given in 3.1.1.3(2) of this Section.

(3) Arms

The thickness of the arms t_a is not to be less than the blade thickness:

$$t_a = t_b \quad \text{mm}$$

The section modulus W is not to be less than:

$$W = 0.5\, s\, C_1^2\, V^2\, K \quad \text{cm}^3$$

where: C_1 — horizontal distance from the aft edge of the rudder to the centreline of the rudder stock, in m;

K — material factor as given in 3.1.1.3(2) or 3.1.1.3 (5) of this Section respectively.

3.1.6 Rudder stock couplings

3.1.6.1 Horizontal flange couplings

(1) The diameter of the coupling bolts d_b is not to be less than:

$$d_b = 0.62\sqrt{d_s^3 K_b / n e_m K_s} \quad \text{mm}$$

where: d_s — stock diameter, taken equal to the greater of the diameters d_t or d_c according to 3.1.4.1 and 3.1.4.2, in mm;

n — total number of bolts, which is not to be less than 6;

e_m — mean distance, in mm, of the bolt axes from the centre of the bolt system;

K_s — material factor for the stock as given in 3.1.1.3(5) of this Section;

K_b — material factor for the bolts as given in 3.1.1.3(5) of this Section.

(2) The thickness of the coupling flanges t_f, in mm, is not to be less than the greater of the following formulae:

$$t_f = d_b\sqrt{K_f / K_b} \quad \text{mm}$$

$$t_f = 0.9 d_b \quad \text{mm}$$

where: K_f — material factor for flange as given in 3.1.1.3(5) of this Section;

K_b — material factor for the bolts as given in 3.1.1.3(5) of this Section;

d_b — bolt diameter, in mm, calculated for a number of bolts not exceeding 8.

(3) The width of material between the perimeter of the bolt holes and the perimeter of the flange is not to be less than 0.67 d_b.

(4) The welded joint between the rudder stock and the flange is to be made in accordance with Figure 3.1.6.1 or equivalent.

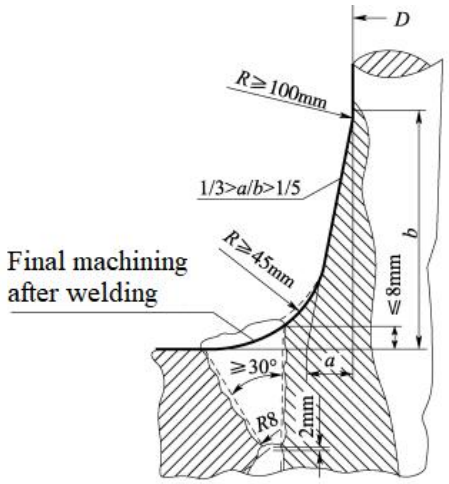

Figure 3.1.6.1 Welded joint between rudder stock and coupling flange

(5) Coupling bolts are to be fitted bolts and their nuts are to be locked effectively.

3.1.6.2 Vertical flange couplings of rudder stock and rudder blades

(1) The diameter of the coupling bolts d_b, in mm, is not to be less than:

$$d_b = 0.81 d_s / \sqrt{n} \times \sqrt{K_b / K_s} \quad \text{mm}$$

where: d_s — stock diameter [in mm] in way of coupling flange;

n — total number of bolts, which is not to be less than 8;

K_b — material factor for bolts as given in 3.1.1.3(5) of this Section;

K_s — material factor for stock as given in 3.1.1.3(5) of this Section.

(2) The first moment of area of the bolts about the centre of the coupling, m, is to be not less than:

$$m = 0.00043\ d_s^3 \qquad \text{cm}^3$$

(3) The thickness of the coupling flanges is to be not less than the bolt diameter, and the width of the flange material between the perimeter of the bolt holes and the perimeter of the flange is to be not less than 0.67 d_b.

(4) Coupling bolts are to be fitted bolts and their nuts are to be locked effectively.

3.1.6.3 Cone couplings with key

(1) Tapering and coupling length

Cone couplings without hydraulic arrangements for mounting and dismounting the coupling are to have a taper c on diameter of 1:8 − 1:12.

Where $c = (d_0 - d_u) / l_c$, see Figure 3.1.6.3(a) and Figure 3.1.6.3(c).

The diameters d_0 and d_u are shown in Figure 3.1.6.3(a) and the cone length, l_c, is defined in Figure 3.1.6.3(c).

The cone coupling is to be secured by a slugging nut. The nut is to be secured, e.g. by a securing plate as shown in Figure 3.1.6.3(a).

The cone shapes are to fit exactly. The coupling length l is to be, in general, not less than $1.5d_0$.

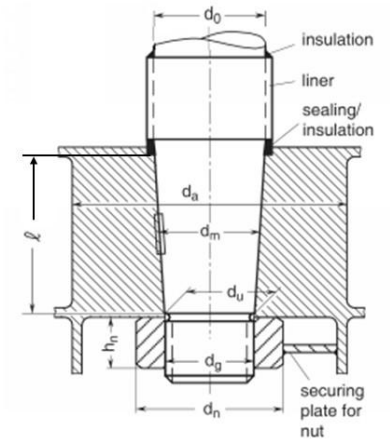

Figure 3.1.6.3(a) Cone coupling with key

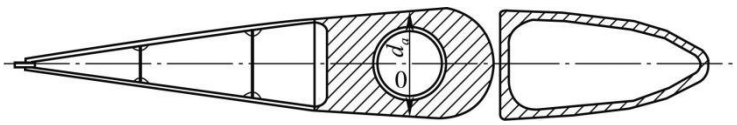

Figure 3.1.6.3(b) Gudgeon outer diameter d_a

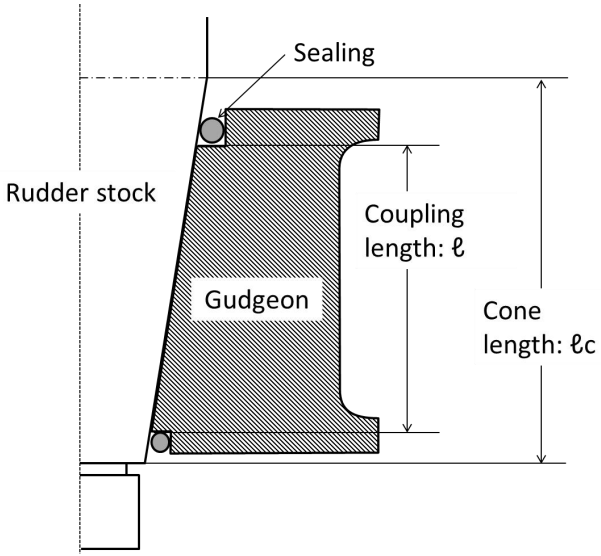

Figure 3.1.6.3(c) Cone length and coupling length

(2) Dimensions of key

For couplings between stock and rudder a key is to be provided, the shear area a_s of which, in cm^2, is not to be less than:

$$a_s = \frac{17.55 Q_F}{d_k R_{eH1}} \quad \text{cm}^2$$

where:

Q_F — design yield moment of rudder stock, in N·m;

$Q_F = 0.02664 d_t^3 / K$ N·m

Where the actual diameter d_{ta} is greater than the calculated diameter d_t, the diameter d_{ta} is to be used. However, d_{ta} applied to the above formula need not be taken greater than 1.145 d_t.

d_t — stock diameter, in mm, according to 3.1.4.1 of this Section;

K — material factor for stock as given in 3.1.1.3(5) of this Section;

d_k — mean diameter of the conical part of the rudder stock, in mm, at the key;

R_{eH1} —specified minimum yield stress of the key material, in N/mm^2.

The effective surface area a_k, in cm^2, of the key (without rounded edges) between key and rudder stock or cone coupling is not to be less than:

$$a_k = \frac{5 Q_F}{d_k R_{eH2}}$$

where: R_{eH2} —specified minimum yield stress of the key, stock or coupling material, in N/mm^2.

(3) The dimensions of the slugging nut are to be as follows (see Figure 3.1.6.3(a)):

external thread diameter: $d_g \geq 0.65\, d_o$,

height: $h_n \geq 0.6\, d_g$,

outer diameter: $d_n \geq 1.2\, d_u$ or $1.5\, d_g$, whichever is the greater.

(4) It is to be proved that 50% of the design yield moment is solely transmitted by friction in the cone couplings. This can be done by calculating the required push-up pressure and push-up length according to 3.1.6.4(2) and 3.1.6.4(3) for a torsional moment $Q'_F = 0.5 Q_F$.

(5) Notwithstanding the requirements of 3.1.6.3(2) and 3.1.6.3(4), where a key is fitted to the coupling between stock and rudder and it is considered that the entire rudder torque is transmitted by the key at the couplings, the scantlings of the key as well as the push-up force and push-up length are to be calculated according to the torque transmitted (not to be greater than the design yielding torque of the rudder stock.

3.1.6.4 Cone couplings with special arrangements for mounting and dismounting the couplings

(1) Where the stock diameter exceeds 200 mm, the press fit is recommended to be effected by a hydraulic pressure connection. In such cases the cone is to be more slender, c ≈1:12 to ≈1:20.

In case of hydraulic pressure connections the nut is to be effectively secured against the rudder stock or the pintle.

For the safe transmission of the torsional moment by the coupling between rudder stock and rudder body the push-up pressure and the push-up length are to be determined according to 3.1.6.4(2) and 3.1.6.4(3) respectively.

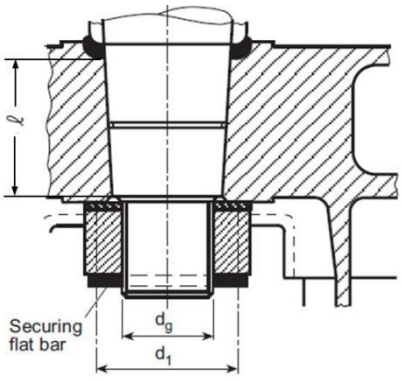

Figure 3.1.6.4 Cone couplings without key

(2) Push-up pressure

The push-up pressure is not to be less than the greater of the two following values:

$$p_{req1} = \frac{2 Q_F \times 10^3}{d_m^{\,2} l \pi \mu_0} \quad \text{N/mm}^2$$

$$p_{req2} = \frac{6M_c \times 10^3}{l^2 d_m} \quad \text{N/mm}^2$$

where: Q_F — design yield moment of rudder stock, as defined in 3.1.6.3(2) of this Section, in N·m;

d_m — mean cone diameter, in mm, see Figure 3.1.6.3(a);

l — coupling length, in mm;

μ_0 — frictional coefficient, equal to 0.15;

M_c — bending moment in rudder stock at the top of the cone coupling (e.g. in case of spade rudders), in N·m.

For spade rudder with trunk extending inside the rudder, the coupling is to be checked against the two cases defined in 2.2, Appendix 1 of this Chapter.

It has to be proved by the designer that the push-up pressure does not exceed the permissible surface pressure in the cone. The permissible surface pressure, in N/mm², is to be determined by the following formula:

$$p_{perm} = \frac{0.95R_{eH}(1-\alpha^2)}{\sqrt{3+\alpha^4}} - p_b \quad \text{N/mm}^2 \quad \text{N/mm}^2$$

where: $p_b = \dfrac{3.5M_c \times 10^3}{d_m l^2}$ N/mm²;

R_{eH} — specified minimum yield stress of the material of the gudgeon, in N/mm²;

$\alpha = \dfrac{d_m}{d_a}$;

d_m — diameter, in mm, see Figure 3.1.6.3(a);

d_a — outer diameter of the gudgeon to be not less than 1.25 d_0, in mm, see Figure 3.1.6.3 (a) and 3.1.6.3(b). (The least diameter is to be considered).

(3) Push-up length

The push-up length Δl, in mm, is to comply with the following formula:

$$\Delta l_1 \le \Delta l \le \Delta l_2$$

where: $\Delta l_1 = \dfrac{p_{req} d_m}{E\left(\dfrac{1-\alpha^2}{2}\right)c} + \dfrac{0.8R_{tm}}{c}$ mm

$$\Delta l_2 = \frac{p_{perm} d_m}{E\left(\frac{1-\alpha^2}{2}\right)c} + \frac{0.8R_{tm}}{c} \quad \text{mm}$$

R_{tm} — mean roughness, in mm, taken equal to 0.01;

c — taper on diameter according to 3.1.6.4(1) of this Section, in mm;

Note: In case of hydraulic pressure connections the required push-up force P_e, in N, for the cone may be determined by the following formula:

$$P_e = p_{req} d_m \pi l \left(\frac{c}{2} + 0.02\right)$$

The value 0.02 is a reference for the friction coefficient using oil pressure. It varies and depends on the mechanical treatment and roughness of the details to be fixed. Where due to the fitting procedure a partial push-up effect caused by the rudder weight is given, this may be taken into account when fixing the required push-up length, subject to approval by CCS.

3.1.7 Pintles

3.1.7.1 Scantlings

The pintle diameter d_p, in mm, is not to be less than:

$$d_p = 0.35\sqrt{BK_p} \quad \text{mm}$$

where: B — relevant bearing force, in N;

k_p — material factor for pintle as given in 3.1.1.3(5) of this Section.

3.1.7.2 Couplings

(1) Tapering

Pintles are to have a conical attachment to the gudgeons with a taper on diameter not greater than:
1:8 to 1:12 for keyed and other manually assembled pintles applying locking by slugging nut,
1:12 to 1:20 on diameter for pintles mounted with oil injection and hydraulic nut.
(2) Push-up pressure for pintle
The required push-up pressure for pintle in case of dry fitting, in N/mm², is to be determined by p_{req1} as given below.
The required push-up pressure for pintle in case of oil injection fitting, in N/mm², is to be determined by the maximum pressure of p_{req1} and p_{req2} as given below:

$$p_{req1} = 0.4\frac{Bd_0}{d_m^2 l} \quad \text{N/mm}^2$$

$$p_{req2} = \frac{6M_{bp}}{l^2 d_m} \times 10^3 \quad \text{N/mm}^2$$

where: B — Supporting force in the pintle, in N;
d_0 — Pintle diameter, in mm, see Figure 3.1.6.3(a);
M_{bp} ——bending moment in the pintle cone coupling to be determined by:

$$M_{bp} = Bl_a \quad \text{N·m}$$

l_a ——length between middle of pintle-bearing and top of contact surface between cone coupling and pintle, see Figure 3.1.7.2..

The push up length Δl_1 is to be calculated similarly as in 3.1.6.4(3) of this Section, using required push-up pressure and properties for the pintle.

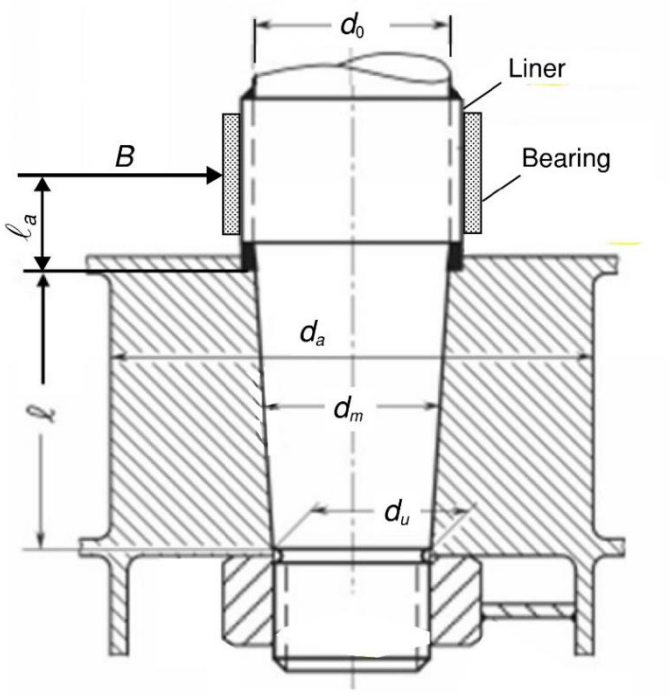

Figure 3.1.7.2 Pintle cone coupling indicating l_a

3.1.7.3 The minimum dimensions of threads and nuts are to be determined according to 3.1.6.3(3).
3.1.7.4 Pintle housing
The length of the pintle housing in the gudgeon is not to be less than the pintle diameter d_p. d_p is to be measured on the outside of shaft sleeves.
The thickness of the pintle housing is not to be less than 0.25 d_p.

3.1.8 Rudder stock bearing, rudder shaft bearing and pintle bearing

3.1.8.1 Liners and bushes

(1) Rudder stock bearing

Liners and bushes are to be fitted in way of bearings. For rudder stocks and pintles having diameter less than 200 mm, liners in way of bushes may be provided optionally. The minimum thickness of liners and bushes t_{min} is to be equal to:

- t_{min} = 8 mm for metallic materials and synthetic material;
- t_{min} = 22 mm for lignum material.

(2) Pintle bearing

The thickness of any liner or bush t, in mm, is not to be less than the minimum thickness defined in 3.1.8.1(1) and the following value:

$$t = 0.01\sqrt{B}$$

where: B— relevant bearing force, in N.

3.1.8.2 Minimum bearing surface

An adequate lubrication is to be provided.

The bearing surface A_b (defined as the projected area: length × outer diameter of liner) is not to be less than:

$$A_b = \frac{P}{q_a} \quad \text{mm}^2$$

where: P — reaction force, in N, in bearing as determined in 3.1.3.2 of this Section;

q_a — allowable surface pressure according to Table 3.1.8.2.

The allowable surface pressure q_a for the various combinations is to be taken as reported in the table below. Higher values than given in Table 3.1.8.2 may be taken in accordance with makers' specifications if they are verified by tests:

Allowable surface pressure q_a **Table 3.1.8.2**

Bush material	q_a (N/mm^2)
Lignum vitae	2.5
White metal, oil lubricated	4.5
Synthetic material with hardness greater than 60 Shore D①	5.5②
Steel③ and bronze and hot-pressed bronze-graphite materials	7.0

Notes:

① Indentation hardness test at 23℃ and with 50% moisture, are to be carried out according to a recognized standard. Synthetic bearing materials are to be of an approved type.

② Surface pressures exceeding 5.5 N/mm^2 may be accepted in accordance with bearing manufacturer's specification and tests, but in no case more than 10 N/mm^2.

③ Stainless and wear-resistant steel in an approved combination with stock liner.

3.1.8.3 Bearing dimensions

The length/diameter ratio of the bearing surface is not to be greater than 1.2.

The bearing length L_p of the pintle is to be such that $D_P \leq L_P \leq 1.2\ D_P$

where: D_p —Actual pintle diameter measured on the outside of liners, in mm.

3.1.8.4 Bearing clearances

With metal bearings, clearances should not be less than d / 1000 + 1.0 mm (where d is the outer diameter of rudder stock or pintle) on the diameter. If non-metallic bearing material is applied, the bearing clearance is to be specially determined considering the material's swelling and thermal expansion properties. This clearance is not to be taken less than 1.5 mm on bearing diameter unless a smaller clearance is supported by the manufacturer's recommendation and there is documented evidence of satisfactory service history with a reduced clearance.

3.1.9 Strength of rudder horns and rudder trunk

3.1.9.1 Rudder horns

The bending moments and shear forces are to be determined by a direct calculation or in line with the guidelines given in 2.4 and 2.5 of Appendix 1 for semi spade rudder with one elastic support and semi spade rudder with 2-conjugate elastic support respectively.

The section modulus around the horizontal x-axis W is not to be less than:

$$W = M_b K / 67 \quad \text{cm}^3$$

where: M_b — bending moment at the section considered, in N·m.

The shear stress τ is not to be larger than:

$$\tau = 48/K \quad \text{N/mm}^2$$

where: K — material factor as given in 3.1.1.3(2) or 3.1.1.3(5) of this Section.

(1) Equivalent stress

At no section within the height of the rudder horn is the equivalent stress to exceed $120/K$ N/mm^2. The equivalent stress σ_v is to be calculated by the following formula:

$$\sigma_v=\sqrt{\sigma_b^2+3\left(\tau^2+\tau_T^2\right)} \quad \text{N/mm}^2$$

where: $\sigma_b=M_b / Z_x$, in N/mm^2;

Z_x — section modulus of rudder horn at the section considered, in cm^3;

$\tau=B_1/A_h$, in N/mm^2;

B_1 — supporting force in the pintle bearing, in N;

A_h — effective shear area of rudder horn in y-direction, in mm^2;

$\tau_T=M_T 10^3/2A_T t_h$, in N/mm^2;

M_T — torsional moment, in N·m;

A_T — area in the horizontal section enclosed by the rudder horn (including the area of inner hollow area), in mm^2;

t_h — plate thickness of rudder horn, in mm;

(2) Rudder horn plating

The thickness of the rudder horn side plating t is not to be less than:

$$t=2.4\sqrt{LK} \quad \text{mm}$$

where: L — length of the ship, in m;

K — material factor, as given in 3.1.1.3(2) or 3.1.1.3(5) of this Section respectively.

(3) Welding and connection to hull structure

The rudder horn plating is to be effectively connected to the aft ship structure, e.g. by connecting the plating to side shell and transverse/ longitudinal girders, in order to achieve a proper transmission of forces, see Figure 3.1.9.1.

If the connection of rudder horn and hull structure is so designed that the rudder horn is transited to hull plating in the curved way, particular attention is to be made to the effectiveness of the bending of rudder horn and the stress of transverse webs.

Brackets or stringer are to be fitted internally in horn, in line with outside shell plate, as shown in Figure 3.1.9.1.

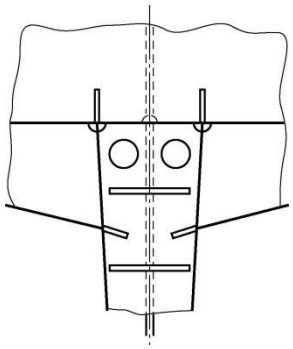

Figure 3.1.9.1 Connection of rudder horn to aft ship structure

Transverse webs of the rudder horn are to be led into the hull up to the next platform deck in a sufficient number.

Strengthened plate floors are to be fitted in line with the transverse webs in order to achieve a sufficient connection with the hull.

The centre line bulkhead (wash-bulkhead) in the after peak is to be connected to the rudder horn.

Scallops are to be avoided in way of the connection between transverse webs and shell plating.

The weld at the connection between the rudder horn plating and the side shell is to be full penetration. The welding radius is to be as large as practicable and may be obtained by grinding.

3.1.9.2 Rudder trunk

The requirements in this paragraph apply to trunk configurations which are extended below stern frame and arranged in such a way that the trunk is stressed by forces due to rudder action.

(1) Materials, welding and connection to hull

The steel used for the rudder trunk is to be of weldable quality, with a carbon content not exceeding 0.23% on ladle analysis or a carbon equivalent C_{EQ} not exceeding 0.41%.

Plating materials for rudder trunks are in general not to be of lower grades than corresponding to class II as defined in Section 3, Chapter 1 of this PART.
The weld at the connection between the rudder trunk and the shell or the bottom of the skeg is to be full penetration.
For rudder trunks extending below shell or skeg, the fillet shoulder radius r, in mm (see Figure 3.1.9.2) is to be as large as practicable and to comply with the following formulae:

$r = 0.1 d_c / K$, without being less than:

r =60 mm when $\sigma = 40/K$ N/mm^2

r = 30 mm when $\sigma < 40/K$ N/mm^2

where: d_c — rudder stock diameter axis as defined in 3.1.4.2;

σ — bending stress in the rudder trunk, in N/mm^2;

K — material factor for the rudder trunk as given in 3.1.1.3(2) or 3.1.1.3(5) of this Section.

The radius may be obtained by grinding. If disk grinding is carried out, score marks are to be avoided in the direction of the weld. The radius is to be checked with a template for accuracy. Four profiles at least are to be checked. A report is to be submitted to the Surveyor.
Rudder trunks comprising of materials other than steel are to be specially considered by CCS.

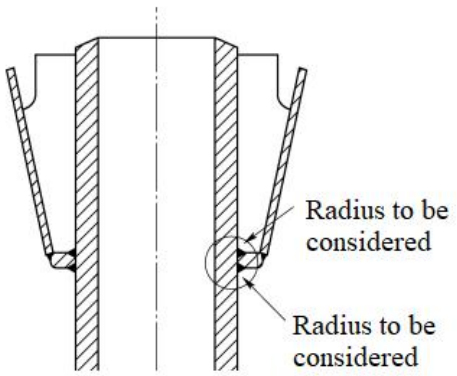

Figure 3.1.9.2

(2) Scantlings
The scantlings of the trunk are to be such that: the equivalent stress due to bending and shear does not exceed 0.35 R_{eH}.
The bending stress on welded rudder trunk σ is to be in compliance with the following formula:

$$\sigma \leqslant 80/K \quad \text{N/mm}^2$$

where: σ — bending stress in the rudder trunk, as defined in 3.1.9.2(1);

K — material factor for the rudder trunk as given in 3.1.1.3(2) or 3.1.1.3(5) of this Section, not to be taken as less than 0.7;

R_{eH} —specified minimum yield stress, in N/mm^2, of the material used.

For calculation of bending stress, the span to be considered is the distance between the mid-height of the lower rudder stock bearing and the point where the trunk is clamped into the shell or the bottom of the skeg.

3.1.10 Others

3.1.10.1 Quadrants and tillers

(1) The section modulus W of the tiller at any section from the centre of the rudder stock about the vertical axis is not to be less than that obtained from the following formula:

$$W = 0.14(1 - \frac{D_S}{R}) D_t^3 (K_t / K_s) \quad \text{mm}^3$$

where: D_s — distance from the section under consideration to the centerline of the stock on the tiller, not greater than the bore diameter of the pin, in mm, see Figure 3.1.10.1;

D_t — stock diameter, in mm, at the tiller, taken not greater than 1.145 times the value calculated according to 3.1.4.1 of this Section;

R — radius of quadrant or length of tiller, in mm;

K_t — material factor of tiller, see 3.1.1.3(5) of this Section;

K_s — material factor of stock, see 3.1.1.3(5) of this Section.

For quadrants having more than one arm, the combined section modulus of the arms is not to be less than that required in the above formula.

For tillers of rectangular section, the breadth to depth ratio is not to be more than 2.

(2) Depth of boss of the quadrant or tiller $h \geq 1.0D_t$, and its outside diameter $D_0 \geq 1.8D_t$, see Figure 3.1.10.1. Where the depth of boss of the tiller h is greater than D_t, the required outer diameter D_0 may be reduced accordingly. It is to ensure that $h \times D_0^2 \geq 3.24D_t^3$, and D_0 is not to be less than $1.6D_t$ in any case. D_t is defined in (1) above.

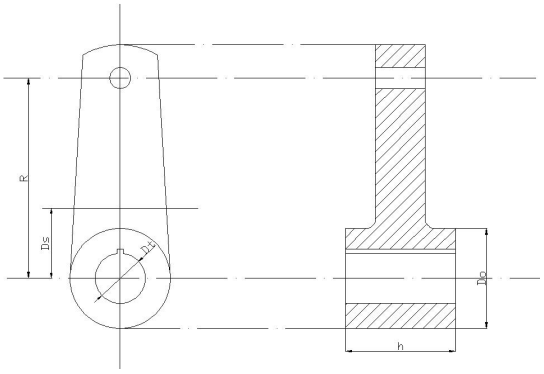

Figure 3.1.10.1

(3) Where the boss of a tiller (quadrant) is composed of two half pieces, at least one key is to be fitted and each end of the key is to be secured by at least 2 bolts. The bolts are to be pretightened and the prestressing force on each bolt is to correspond to 70% of the permissible stress of bolt material. Where double keys are used, the prestressing force may be reduced appropriately. The total cross-sectional area A_b of all bolts is not to be less that obtained from the following formula:

$$A_b = 0.2 \times \frac{D_t^3}{b}(K_b/K_s) \quad \text{mm}^2$$

where: D_t — stock diameter, in mm, at the tiller, taken not greater than 1.145 times the value calculated according to 3.1.4.1 of this Section;

b — distance between centerlines of bolt at both ends, in mm;

K_b — material factor of bolt, see 3.1.1.3(5) of this Section;

K_s — material factor of stock, see 3.1.1.3(5) of this Section.

(4) The cross-sectional area A_r and moment of inertia I_r of the rod connecting the tiller (quadrant) to the tiller are not to be less than those obtained from the following formulas:

$$A_r = 0.12 \times \frac{D_t^3}{R}(K_r / K_s) \quad \text{mm}^2$$

$$I_r = 6.6\frac{D_t^3 l^2}{R} \times 10^{-6}(K_r / K_s) \quad \text{mm}^4$$

where: D_t — diameter of the rudder stock, at the tiller of a passive rudder, taken not greater than 1.145 times the value calculated according to 3.1.4.1 of this Section;

l — length of the connecting rod, in mm;

R — length of the tiller of the passive rudder, in mm;

K_r — material factor of connecting rod, see 3.1.1.3(5) of this Section;

K_s — material factor of stock, see 3.1.1.3(5) of this Section.

(5) For a rotary vane type steering gear, the rotor and blades of the gear are to comply with the requirements of 3.1.10.1(1) and 3.1.10.1(2) for boss of the tiller and the tiller.

3.1.10.2 Connection of rudder tiller to stock

(1) The connection of the rudder tiller to stock is to be such that mechanical forces are transmitted from the steering gear to the rudder stock in any operational condition. The torque T_d transmitted by such connection is not to be less than twice the design torque of the steering gear, but need not be greater than the design yield torque Q_F of the stock calculated according to 3.1.6.3(2) of this Section. The design torque of the steering gear is corresponding to the design pressure in 13.1.6.5 of Chapter 13, PART THREE of the Rules.

(2) For torque transmission by friction, the average surface pressure p_r for the connection of tiller to stock is not to be less than that obtained from the following formula:

$$p_r \geq \frac{2T_{fr}}{\pi D_m^2 lf} \times 10^3 \quad \text{N/mm}^2$$

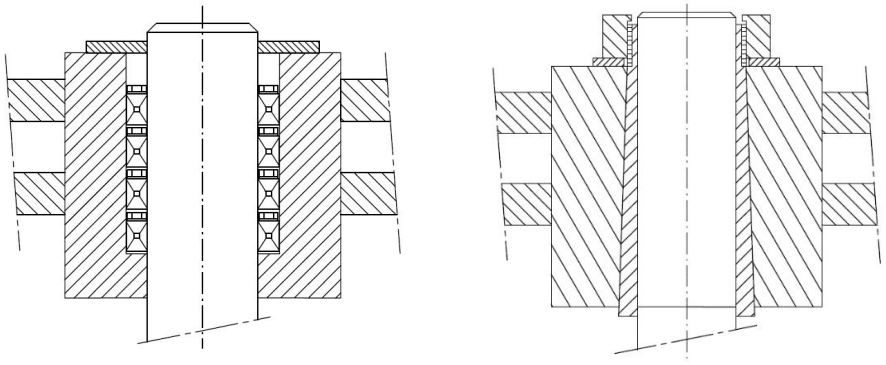
where: T_{fr} — torque transmitted by friction, in N·m;
= T_d, for keyless connection;
= $0.5T_d$, for keyed connection;
T_d — torque transmitted through connection of tiller to stock, in N·m, determined according to 3.1.10.2(1) of this Section;
D_m — diameter of the rudder stock or mean diameter of the taper, in mm;
l — length of the effectively connected portion of the tiller, in mm;
f — coefficient of friction, taken as 0.15 for hydraulic fit or 0.18 for dry fit.

(3) For conical connection, nuts are to be used for securing against axial displacement. It is to be ensured that the size of nuts is to sustain the weight of rudder and rudder stock without considering the force of friction between rudder tiller and rudder stock, and reference may be made to the requirements of 3.1.6.3(3) of this Section.

(4) Where the tiller is connected to the stock by means of several expansion sleeves or conical sleeves, as indicated in Figure 3.1.10.2, the influence of axial forces is also to be taken into account. In this case, the torque T_{d1} transmitted by the connection of tiller to stock is not to be less than that obtained from the following formula:

$$T_{d1}=\sqrt{T_d^2+(2\cdot W\cdot D_m)^2\cdot 10^{-4}} \quad \text{N·m}$$

where: T_d — torque, in N·m, determined according to 3.1.10.2(1) of this Section;
W — weight of rudder and rudder stock, in kg;
D_m — diameter of rudder stock, in mm.



(a) Expansion sleeve (b) Conical sleeve

Figure 3.1.10.2

(5) The taper of cone on diameter is to be not greater than 1:15 for keyless conical connection and not greater than 1:10 for keyed conical connection.

(6) For keyed connection, the shear area As of the key is not to be less than that obtained from the following formula:

$$A_s=\frac{70\left(T_d-k_{key}T_{fr}\right)}{D_k R_{eH}} \quad \text{cm}^2$$

where: T_d — torque transmitted through connection of tiller to stock, in N·m, calculated according to 3.1.10.2 of this Section;
k_{key} — coefficient, determined as follows:
= 0.7 where boss of tiller is composed of two half pieces and secured by bolts;
= 0.9 for hydraulic fitting of tiller to stock;
= 1.0 in other cases.
T_{fr} — torque transmitted by friction, in N·m, calculated according to the following formula:

$$T_{fr}=\frac{\pi p_r D_m^2 lf}{2}\times 10^{-3}$$

where: p_r — average surface pressure for the connection of tiller to stock, in N/mm^2, determined according to 3.1.10.2(2) of this Section. Where hydraulic fitting or shrinkage fit is adopted for the conical connection, the average push-up surface pressure is to be taken;
D_m, l, f — same as in 3.1.10.2(2) of this Section;
D_k — mean diameter, in mm, of rudder stock cone in way of the position where the key is fitted;
R_{eH} — yield stress, in N/mm^2, of key material.

(7) For keyed connections, the compressed area A_k of keys (round edge portion not included) is not to be less than that obtained from the following formula:

$$A_k = \frac{22(T_d - k_{key} T_{fr})}{D_k R_{eH}} \quad \text{cm}^2$$

where: T_d , k_{key}, T_{fr} , D_k — same as in (6) above;

R_{eH} — yield stress, in N/mm^2, of key material.

(8) Where two keys are fitted, the shear area A_s and compressed area A_k of each key may be taken as 2/3 of the value obtained for one key.

(9) The keyway is to have an adequately rounded end. The radius of curvature is usually not to be less than 5% of the thickness of the key. The compressive stress on the stock/tiller keyway is not to exceed 90% of the yield stress of the material used.

(10) Where the hydraulic fitting or shrinkage fit is adopted for the conical connection, the push-up length and the average push-up surface pressure are to be determined in accordance with the following requirements:

① The push-up length S is to meet the following:

$$S_1 \le S \le S_2$$

The minimum push-up length $S_1 = \frac{1}{k_1}[\frac{2 p_r D_m k_2^2}{E(k_2^2 - 1)} + 0.02]$ mm

The maximum push-up length $S_2 = \frac{1}{k_1}[1.6 R_{eH} D_m \frac{k_2^2}{E\sqrt{3k_2^4 + 1}} + 0.02]$ mm

where: p_r — average surface pressure for the connection of tiller to stock, in N/mm^2, determined according to 3.1.10.2(2) of this Section;

k_1 — taper of cone on diameter;

$k_2 = (D_m + 2t_a) / D_m$;

D_m — mean diameter of cone, in mm;

t_a — mean thickness of boss of tiller, in mm;

R_{eH} — yield stress of material of boss of tiller or rudder stock, whichever is less, in N/ mm^2;

E — elastic modulus, to be taken as 2.06×10^5, in N/mm^2.

② The average push-up surface pressure P is to be calculated by the following formula:

$$P = \frac{SE(k_2^2 - 1)k_1}{2D_m k_2^2} \quad \text{N/ mm}^2$$

where: k_1, k_2, D_m and E — same as in ① above;

S — the push-up length to be determined in accordance with ① above, in mm.

3.1.10.3 Strengthening for navigation in ice

(1) For ships with Ice Class notations the scantlings and arrangement of the rudder structures are to comply with the relevant requirements of Chapter 4 of this PART.

Section 2 ANCHORING AND MOORING EQUIPMENT

3.2.1 Equipment number

3.2.1.1 The anchoring equipment for sea-going ships are to be provided in accordance with Tables 3.2.1.1(1) and 3.2.1.1(2), based on the ship type and service area as well as the equipment number derived from 3.2.1.2 of this Section. Requirements of this Section for the number, length and breaking loads of towlines and mooring lines are only as guidance.

For non-self-propelled ships engaged in special work, of which an increased mass of anchors is required by the owner and anchoring operations are carried out by means of other appliances, chain cables may be provided in accordance with the rule requirements for the mass of anchors only.

The requirement for the anchoring equipment in this Section is intended for temporary mooring of a vessel within a harbour or sheltered area when the vessel is awaiting berth, tide, etc.

The equipment is therefore not designed to hold a ship off fully exposed coasts in rough weather or to stop a ship which is moving or drifting. In this condition the loads on the anchoring equipment increase to such a degree that its components may be damaged or lost owing to the high energy forces generated, particularly in large ships.

The anchoring equipment presently required in this Section is designed to hold a ship in good holding ground in conditions such as to avoid dragging of the anchor. In poor holding ground the holding power of the anchors will be significantly reduced.

The Equipment Numeral (EN) formula for anchoring equipment required in this Section is based on an assumed maximum current speed of 2.5 m/sec, maximum wind speed of 25 m/sec and a minimum scope of chain cable between 6 and 10, the scope being the ratio between length of chain paid out and water depth. For ships with an equipment length greater than 135 m, alternatively the required anchoring equipment can be considered applicable to a maximum current speed of 1.54 m/s, a maximum wind speed of 11 m/s and waves with maximum significant height of 2 m.

It is assumed that under normal circumstances a ship will use only one bow anchor and chain cable at a time.

Manufacture of anchors and anchor chain cables is to be in accordance with the relevant requirements of CCS Rules for Materials and Welding.

The bower anchor is to be connected with its chain cable, arranged onboard the ship and ready for use.

In addition to planned anchoring for normal operations, anchoring equipment is also important for ship safety in emergency situations such as loss of maneuverability, unscheduled repairs and other unexpected situations.

Equipment Required **Table 3.2.1.1(1)**

Ship type	Required equipment
Cargo ships, bulk carriers, oil tankers, trailing suction dredgers, ferries, etc.	Using *N*
Tugs	Using *N*
Offshore supply ships	Using *N*, but the chain cables are to be selected 2 grades above *N*
Manned barges	Using *N*
Unmanned barges	Using *N*, but only one bower anchor is required, and 0.5 times the length of chain cables required for *N* may be provided
Floating cranes, floating pile drivers or other similar workboats	Using *N*, but side projections of the crane, pile driver, etc., are to be considered for *N*. If the anchors used comply with the requirements of this Table, they may be used in lieu of bower anchors.

3.2.1.2 The equipment number *N* is to be obtained from the following formula:

$$N = \Delta^{\frac{2}{3}} + 2(Bh + S_{fun}) + \frac{A}{10}$$

where: Δ — moulded displacement, in t, to the summer load waterline;

B — moulded breadth, in m;

h — effective height, in m, from the summer load waterline to the top of the uppermost house, i.e.:

$$h = a + \sum h_i$$

where: a — vertical distance at hull side, in m, measured from the summer load waterline amidships to the upper deck;

h_i — height at the centreline, in m, of each tier of houses having a breadth greater than $B/4$; for the lowest tier h_1 is to be measured at centreline from the upper deck or from a notional deck line where there is local discontinuity in the upper deck, see Figure 3.2.1.1(1);

A — area, in m², in profile view of the hull, within the length of the vessel, and of superstructures and deckhouses and funnels above the summer load waterline, which are within the length of the vessel, and also having a breadth greater than $B/4$. The side projected area of the funnel is considered in A when A_{FS} is greater than zero. In this case, the side projected area of the funnel should be calculated between the upper deck, or notional deck line where there is local discontinuity in the upper deck, and the effective height h_F;

S_{fun} — effective front projected area of the funnel, in m², defined as:

$$S_{fun} = A_{FS} - S_{shield}$$

where: A_{FS}— front projected area of the funnel, in m² , calculated between the upper deck at centreline, or notional deck line where there is local discontinuity in the upper deck, and the effective height h_F. A_{FS} is taken equal to zero if the funnel breadth is less than or equal to B/4 at all elevations along the funnel height;

h_F— effective height of the funnel, in m, measured from the upper deck at centreline, or notional deck line where there is local discontinuity in the upper deck, and the top of the funnel. The top of the funnel may be taken at the level where the funnel breadth reaches B/4;

S_{shield} — the section of front projected area A_{FS}, in m², which is shielded by all deck houses having breadth greater than B/4. If there are more than one shielded section, the individual shielded sections i.e $S_{shield1}$, $S_{shield\ 2}$ etc as shown in Figure 3.2.1.2(3) to be added together. To determine S_{shield}, the deckhouse breadth is assumed B for all deck houses having breadth greater than B/4 as shown for $S_{shield1}$, $S_{shield2}$ in Figure 3.2.1.2(3). When several funnels are fitted on the ship, the above parameters are taken as follows:

h_F— effective height of the funnel, in m, measured from the upper deck, or notional deck line where there is local discontinuity in the upper deck, and the top of the highest funnel. The top of the highest funnel may be taken at the level where the sum of each funnel breadth reaches B/4;

A_{FS}— sum of the front projected area of each funnel, in m² , calculated between the upper deck, or notional deck line where there is local discontinuity in the upper deck, and the effective height h_F. A_{FS} is to be taken equal to zero if the sum of each funnel breadth is less than or equal to B/4 at all elevations along the funnels height;

A — Side projected area, in m², of the hull, superstructures, houses and funnels above the Summer Load waterline which are within the length of the ship. The total side projected area of the funnels is to be considered in the side projected area of the ship, A, when A_{FS} is greater than zero. The shielding effect of funnels in transverse direction may be considered in the total side projected area, i.e., when the side projected areas of two or more funnels fully or partially overlap, the overlapped area needs only to be counted once.

The equipment number of tugs is to be determined by the following formula:

$$N = \Delta^{\frac{2}{3}} + 2(aB + \sum b_i\ h_i) + \frac{A}{10}$$

where: a, B and h_i — same as defined above;

b_i — breadth, in m, of superstructures or of deckhouses of each tier having a breadth greater than B/4.

For tugs under 45 m in length intended for towing service only, one anchor may be used onboard provided that the second anchor and its relevant chain cable holds readily available to be installed. In case of loss of anchor, the tug is to remain in port until replace anchor equipment is installed onboard.

In the calculation of h and A, sheer and trim are to be ignored, i.e. h is the sum of freeboard amidships plus the height (at centreline) of each tier of houses having a breadth greater than B/4.

Screens and bulwarks more than 1.5 m in height are to be regarded as parts of superstructures or deckhouses.

Screens and bulwarks more than 1.5 m in height are to be regarded as parts of superstructures or deckhouses.

If a house having a breadth greater than B/4 is above a house with a breadth of B/4 or less then the wide house is to be included but the narrow house ignored.

The height of the hatch coamings and that of any deck cargo, such as containers, may be disregarded when determining h and A. With regard to determining A, when a bulwark is more than 1.5 m high, the area

shown as A_2 in Figure 3.2.1.2(2) is to be included in A. The total length of chain given in Table 3.2.1.1(2) is to be divided in approximately equal parts between the two bower anchors.
For ships of length less than 90 m, alternative methodology using direct force calculation for anchoring equipment described in appendix 3 of this Chapter may be used.

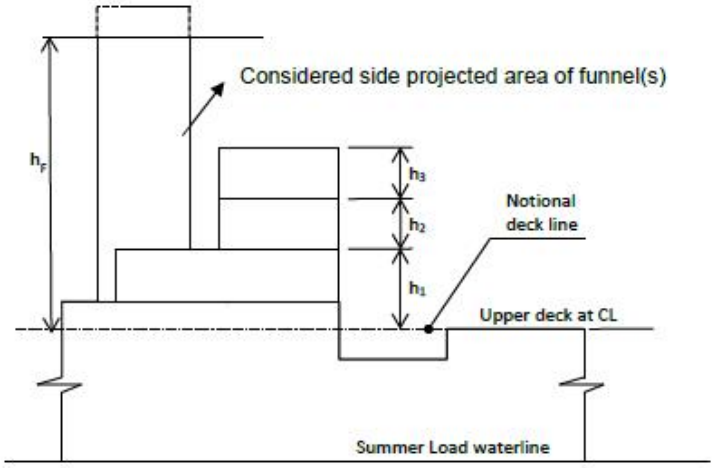


Figure 3.2.1.2(1)

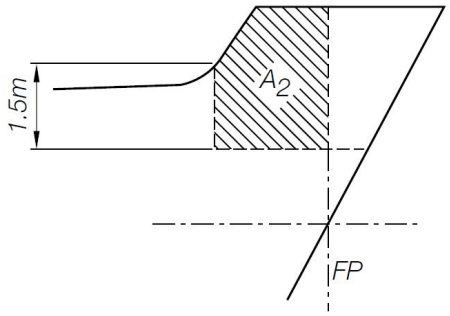

Figure 3.2.1.2(2)

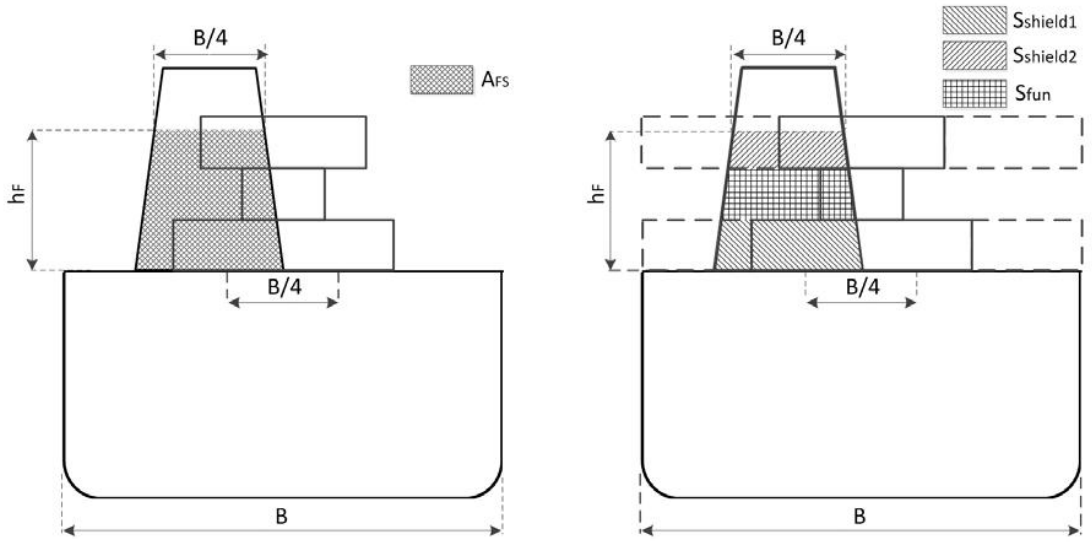

Figure 3.2.1.2(3)

3.2.2 Anchors

3.2.2.1 The mass of individual bower anchors may vary within -7% to +7% of the mass given in Table 3.2.1.1(2) of this Section, provided that the total mass of the bower anchors is not to be less than that would have been required for anchors of equal mass.

3.2.2.2 The mass of the head, including pins and swivels, of an ordinary stockless anchor is not to be less than 60% of the total mass of the anchor.

3.2.2.3 Stocked bower anchors may be used, but the mass excluding the stock is not to be less than 80% of the mass given in Table 3.2.1.1(2) of this Section for ordinary stockless bower anchors.

3.2.2.4 When high holding power anchors are used as bower anchors, the mass of each such anchor may be 75% of the mass given in Table 3.2.1.1(2) of this Section for ordinary stockless bower anchors. When super high holding power anchors of the proven holding power are used as bower anchors, the mass of each such anchor may be reduced to not less than 50% of the mass required for ordinary stockless anchors in Table 3.2.1.1(2) of this Section. See specific requirements of Section 1, Chapter 10 of PART ONE of CCS Rules for Materials and Welding. Where high holding power anchors or very high holding power anchors are used as bower anchors, leading to the reduction in the mass of anchors, the notation RWA may be assigned.

Anchoring and Towing Equipment **Table 3.2.1.1(2)**

3.2.3 Chain cables

3.2.3.1 For ships with *N* less than 90, chain cables may be substituted by studless chains of equivalent proof-load.

3.2.3.2 Wire rope may be used in place of chain cable on ships subject to the following conditions:

(1) with less than 90 m in length and which will need an anchor for emergency purposes, i.e., not intended to use their anchor in normal temporary anchoring operation, or

(2) with the anchoring equipment used for positioning with a minimum of 4 points anchoring, e.g., for cable or pipe laying.

(3) for anchors used for operation of floating cranes, floating pile drivers or other similar workboats as specified in Table 3.2.1.1(1).

3.2.3.3 Use of wire rope is subject to the following conditions:

(1) The wire ropes are to have a total length equal to 1.5 times the corresponding length of stud link chain cables required in Table 3.2.1.1(2), and a minimum breaking load equal to that given for the corresponding stud link chain cable of Grade CCS 1.

(2) The anchor weight shall be increased by 25 % compared to anchor associated with chain cable according to Table 3.2.1.1(2).

(3) A short length of chain cable is to be fitted between the wire rope and the anchor, having a length equal to 12.5 m or the distance from the anchor in the stowed position to the winch, whichever is the lesser.

(4) All surfaces being in contact with the wire need to be rounded with a radius of not less than 10 times the wire rope diameter (including stem).

(5) Steel wire shall be selected to fit for purpose based on the manufacturer recommendation and shall be provided with guidance for maintenance and inspection.

3.2.3.4 A swivel is to be provided to the chain cables at the outboard end to which the anchor is connected.

3.2.3.5 The inboard end of the chain cable is to be connected to the structure by fasteners and so arranged that they will be capable of being immediately released from a position easily accessible outside the chain locker. Fasteners and their hull support structures are to be able to withstand breaking load which is not less than 15% and not greater than 30% of the anchor chain fitted.

3.2.3.6 Grade CCS 1 material having a tensile stress of less than 400 N/mm² is not to be used in association with high holding power anchors. Grade CCS 3 material is to be used only for chains of 20.5 mm or more in diameter.

3.2.3.7 The total length of chain given in Table 3.2.1.1(2) is to be divided in approximately equal parts between the two bower anchors.

3.2.4 Towlines and mooring lines

3.2.4.1 The number, length and breaking loads of mooring lines are to be marked on the mooring arrangement plan of the ship. The towlines listed in Table 3.2.1.1(2) are provided on board for the tug or for the use by other ships towing the ship. The lateral projected area of deck cargoes as given by the ship nominal capacity condition is to be taken into account during the calculation of equipment number for

selection of towing lines. As an alternative method to 3.2.4, the number and strength of mooring lines may be determined by means of direct mooring analysis of Appendix 2 of this Chapter.

3.2.4.2 Mooring lines for ships with EN $\leqslant$ 2000 are to be determined according to Table 3.2.1.1(2). For ships having the ratio A/N > 0.9, number of lines given in Table 3.2.1.1(2) is to be added to the number of mooring lines according to the following formulae:

One line where $0.9 < \frac{A}{\mathrm{N}} \leq 1.1$

two lines where $1.1 < \frac{A}{\mathrm{N}} \leq 1.2$

three lines where $1.2 < \frac{A}{\mathrm{N}}$

3.2.4.3 The strength of mooring lines and the number of head, stern, and breast lines (see Figure 3.2.4.2) for ships with an Equipment Number EN > 2000 are based on the side-projected area A_1. Side projected area A_1 is to be calculated similar to the side-projected area A according to 3.2.1.2 but considering the following conditions:

Ballast draft is to be considered for the calculation of the side-projected area A_1. For ship types with small change of draft, e.g. passenger ships and ro-ro ships, the summer load waterline may be used for the calculation of the side-projected area A_1.

Wind shielding of the pier can be considered for the calculation of the side-projected area A_1 unless the ship is intended to be regularly moored to jetty type piers. A height of the pier surface of 3 m over waterline may be assumed, i.e. the lower part of the side projected area with a height of 3 m above the waterline for the considered loading condition may be disregarded for the calculation of the side-projected area A_1.

Deck cargo as given by the nominal capacity condition (as defined in 3.6.2.10 of this Chapter) is to be included for the determination of side-projected area A_1. The summer load waterline may be used for the calculation of condition with deck cargo. Deck cargo may not need to be considered if a ballast draft condition generates a larger side-projected area A_1 than the full load condition with cargo on deck. The larger of both side-projected areas is to be chosen as side-projected area A_1.

(1) The mooring lines as given here under are based on a maximum current speed of 1.0 m/s and the following maximum wind speed, in m/s:

V_W $= 25 - 0.002(A_1 - 2000)$ for passenger ships, ferries, and car carriers with 2000 $m^2 < A_1 \leq 4000$ m^2

$= 21$ for passenger ships, ferries, and car carriers with $A_1 > 4000$ m^2

$= 25$ for other ships

The wind speed is considered representative of a 30 second mean speed from any direction and at a height of 10 m above the ground. The current speed is considered representative of the maximum current speed acting on bow or stern (±10°) and at a depth of one-half of the mean draft. Furthermore, it is considered that ships are moored to solid piers that provide shielding against cross current. Additional loads caused by, e.g., higher wind or current speeds, cross currents, additional wave loads, or reduced shielding from non-solid piers may need to be particularly considered. Furthermore, it is to be observed that unbeneficial mooring layouts can considerably increase the loads on single mooring lines.

Breast line: A mooring line that is deployed perpendicular to the ship, restraining the ship in the off-berth direction.

Spring line: A mooring line that is deployed almost parallel to the ship, restraining the ship in fore or aft direction.

Head/Stern line: A mooring line that is oriented between longitudinal and transverse direction, restraining the ship in the off-berth and in fore or aft direction. The amount of restraint in fore or aft and off-berth direction depends on the line angle relative to these directions.

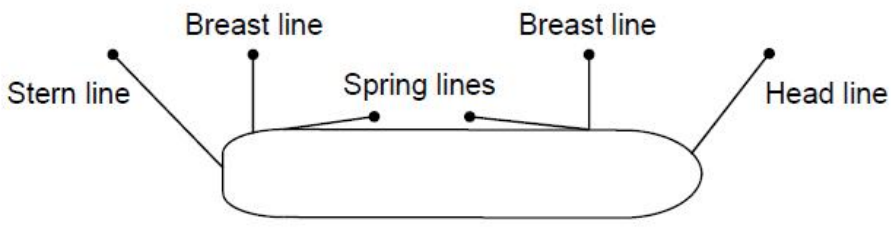

Figure 3.2.4.2 Breast line, spring line, head/stern line

(2) The ship design minimum breaking strength, in kN, of the mooring lines for ships with EN>2000 is not to be less than the value obtained from the following formula and to be limited to 1275 kN:

$$MBL_{SD} = 0.1 \cdot A_1 + 350 \qquad \text{kN}$$

However, in this case the mooring lines are to be considered as not sufficient for the wind speed given in (1), the acceptable wind speed V_W^*, in m/s, can be estimated as follows:

$$V_W^* = V_W \sqrt{\frac{MBL_{SD}^*}{MBL_{SD}}}$$

where: V_w is the wind speed as per (1);

MBL_{SD}^* is the ship design breaking strength of the mooring lines intended to be supplied, to be taken less than corresponding to an acceptable wind speed of 21 m/s:

$$MBL_{SD}^* \geq \left(\frac{21}{V_W}\right)^2 \cdot MBL_{SD}$$

MBL_{SD} — the breaking strength as recommended according to the formula in (2).

If lines are intended to be supplied for an acceptable wind speed V_W^* higher than V_W as per (1), the ship design minimum breaking strength is to be taken as:

$$MBL_{SD}^* = \left(\frac{V_W^*}{V_W}\right)^2 \cdot MBL_{SD}$$

(3) The total number of head, stern and breast lines for ships with EN>2000 is not to be less than:

$$n = 8.3 \cdot 10^{-4} \cdot A_1 + 6$$

For oil tankers, chemical tankers, bulk carriers, and ore carriers the total number of head, stern and breast lines is to be taken as:

$$n = 8.3 \cdot 10^{-4} \cdot A_1 + 4$$

The total number of head, stern and breast lines is to be rounded to the nearest whole number.

(4) The number of head, stern and breast lines may be increased or decreased in conjunction with an adjustment to the strength of the lines. The adjusted strength, MBL_{SD}^{**}, is to be taken as:

$$MBL_{SD}^{**} = 1.2 \cdot MBL_{SD} \cdot n / n^{**} \leq MBL_{SD} \qquad \text{for increased number of lines,}$$

$$MBL_{SD}^{**} = MBL_{SD} \cdot n / n^{**} \qquad \text{for reduced number of lines.}$$

where: MBL_{SD} is MBL_{SD} or MBL_{SD}^* specified in (1) and (2) of this paragraph;

n^{**} is the increased or decreased total number of head, stern and breast lines;

n the number of lines for the considered ship type as calculated by the above formulas without rounding.

(5) The total number of spring lines is to be taken not less than:

Two lines where EN < 5000,

Four lines where EN $\geqslant$ 5000.

The ship design minimum breaking strength of spring lines is to be the same as that of the head, stern and breast lines. If the number of head, stern and breast lines is increased in conjunction with an adjustment to the ship design minimum breaking strength of the lines, the number of spring lines is to be increased in accordance with the following formula, but rounded up to the nearest even number.

$$n_S^* = MBL_{SD} / MBL_{SD}^{**} \cdot n_S$$

where: MBL_{SD} is MBL_{SD} or MBL_{SD}^* specified in (1) and (2) of this paragraph;

n_S is the number of spring lines;

n_S^* is the increased number of spring lines.

3.2.4.4 The length of mooring lines for ships with EN of less than or equal to 2000 may be taken from Table 3.2.1.1(2). For ships with EN > 2000 the length of mooring lines may be taken as 200 m. The lengths of individual mooring lines may be reduced by up to 7% of the above given lengths, but the total length of mooring lines is not to be less than would have resulted had all lines been of equal length.

3.2.4.5 The wire ropes for towlines listed in Table 3.2.1.1(2) of this Section are to be of a flexible, galvanized construction having a breaking strength of not less than 1.37 kN/mm^2 per wire. The construction type of the wire ropes is to be referred to the provisions in Section 4, Chapter 10, PART ONE of CCS Rules for Materials and Welding.

3.2.4.6 Towlines and mooring lines may be of natural fibre, synthetic fibre material or a mixture of wire and natural fibre. In no case is the circumference of the ropes made of natural fibre or synthetic fibre to be less than 63 mm (20 mm in diameter).

3.2.4.7 All ropes having a breaking strength in excess of 736 kN are to be handled by specially designed winches.

3.2.4.8 In engineering ships, service winches may be used in lieu of windlasses, provided that these winches can efficiently handle chain cables.

3.2.5 Strength requirements for securing of windlasses on fore decks

3.2.5.1 Paragraph 3.2.5 of this Section provides strength requirements for the securing of windlasses located on the exposed deck over the forward 0.25L of all ships of 80 m or over in length, where the height of the exposed deck in way of the windlasses is less than 0.1L or 22 m above the summer load waterline, whichever is the lesser.

3.2.5.2 Where mooring winches are integral with the anchor windlass, they are to be considered as part of the windlass.

3.2.5.3 The following pressures and associated areas are to be applied (see Figure 3.2.5.3):

(1) Force P_x = 200 kN/m^2 normal to the shaft axis and away from the forward perpendicular, over the projected area in this direction.

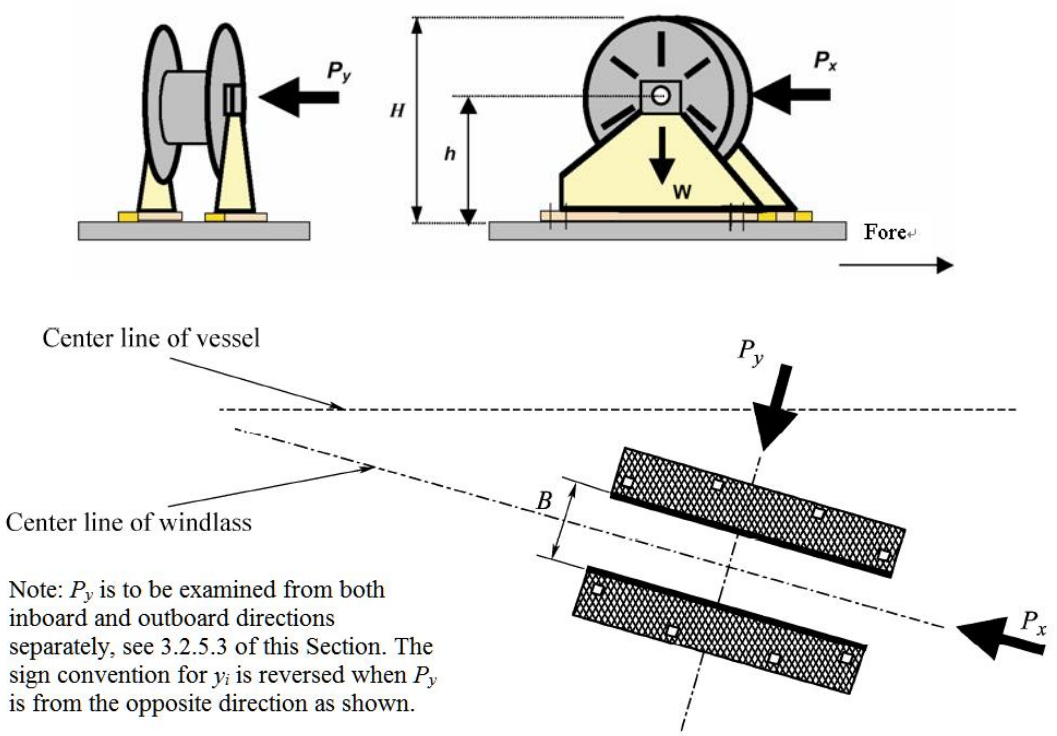
(2) Force P_y = 150 kN/m^2 parallel to the shaft axis and acting both inboard and outboard separately, over the multiple of f times the projected area in this direction, where f is defined as:

$$f = 1 + \frac{B}{H}, \text{ but not greater than 2.5}$$

where: B — width of windlass measured parallel to the shaft axis, in m;

H — overall height of windlass, in m.

3.2.5.4 Forces in the bolts, chocks and stoppers securing the windlass to the deck are to be calculated. The windlass is supported by N bolt groups, each containing one or more bolts, see Figure 3.2.5.3.



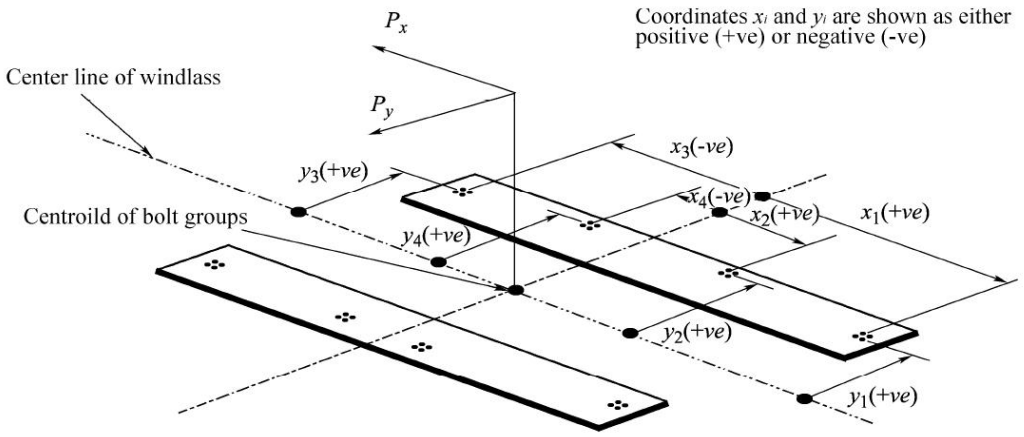


Figure 3.2.5.3

3.2.5.5 The axial force R_i in bolt group (or bolt) i, may be calculated from:

$$R_{xi} = \frac{P_x h x_i A_i}{I_x} \quad \text{kN}$$

$$R_{yi} = \frac{P_y h y_i A_i}{I_y} \quad \text{kN}$$

$$R_i = R_{xi} + R_{yi} - R_{si} \quad \text{kN}$$

where: P_x — force acting normal to the shaft axis, in kN;

P_y — force acting parallel to the shaft axis, in kN, either inboard or outboard, whichever gives the greater force in bolt group i;

h — shaft height above the windlass mounting, in cm;

x_i, y_i — x and y coordinates of bolt group i from the centroid of all N bolt groups, positive in the direction opposite to that of the applied force, in cm;

A_i — cross sectional area of all bolts in group i, in cm^2;

$I_x = \sum A_i x_i^2$, in cm^4, sum of moments of inertia for N bolt groups about y-axis;

$I_y = \sum A_i y_i^2$, in cm^4, sum of moments of inertia for N bolt groups about x-axis;

R_{si} — static reaction at bolt group i, due to weight of windlass, in kN.

3.2.5.6 Shear forces F_{xi}, F_{yi} applied to the bolt group i, and the resultant combined force F_i may be calculated from:

$$F_{xi} = \frac{P_x - agW}{N} \quad \text{kN}$$

$$F_{yi} = \frac{P_y - agW}{N} \quad \text{kN}$$

$$F_i = \sqrt{F_{xi}^{\ 2} + F_{yi}^{\ 2}} \quad \text{kN}$$

where: α — coefficient of friction, taken as 0.5;

W — mass of windlass, in t;

g — gravity acceleration, taken as 9.81m/s^2;

N — number of bolt groups.

3.2.5.7 Axial tensile and compressive forces in 3.2.5.5 of this Section and lateral forces in 3.2.5.6 of this Section are to be considered in the design of the supporting structure.

3.2.5.8 Tensile axial stresses in the individual bolts in each bolt group are to be calculated. The horizontal forces F_{xi} and F_{yi} are normally to be reacted by shear chocks. Where "fitted" bolts are designed to support these shear forces in one or both directions, the equivalent stresses in the individual bolts are to be calculated, and compared to the stress under proof load. The safety factor against bolt proof strength is not to be less than 2.0. Where pourable resins are incorporated in the holding down arrangements, due account is to be taken in the calculations.

3.2.5.9 Direct calculation is to be performed for the strength of the deck framing supporting the windlass and its securing bolt loads as defined in 3.2.5.3 to 3.2.5.7 of this Section.

Section 3 CEILINGS AND CARGO BATTENS

3.3.1 Ceiling

3.3.1.1 Wood ceiling is to be laid from the floors to the upper part of the bilge in single bottom ships, and over the bilges in ships having double bottoms. The ceiling is to be arranged so as to be readily removable for inspection.

3.3.1.2 Where ceiling is to be laid on the inner bottom under hatchways, battens are to be laid underneath the ceiling, and the thickness of the battens is to be at least 30 mm. Where the double bottom tank is not intended to carry oil fuel, ceiling may be laid directly on the inner bottom plating embedded in a suitable bituminous solution or other effective coverings.

3.3.1.3 Either in single or double bottom ships, the thickness of the ceiling in cargo holds is to be determined according to the ship's length L as follows:

for $L \leq 60$ m, not less than 50 mm;

for 60 m $< L \leq 90$ m, not less than 55 mm;

for $L > 90$ m, not less than 60 mm.

3.3.1.4 Bottom ceiling or shaft tunnel ceiling under hatchways may be omitted provided that the thickness of the inner bottom plating or shaft tunnel top plating is increased by 2 mm.

3.3.1.5 If cargo is handled by grabs or similar mechanical appliances, double layers of ceiling are to be fitted on the inner bottom under hatchways (the thickness of each ceiling layer is to be in compliance with 3.3.1.3 of this Section); if the thickness of the inner bottom plating is increased by 5 mm, the wood ceiling may be omitted.

3.3.1.6 If cargo is carried in a hold adjacent to a deep oil tank with heating appliances, the hold side of the bulkhead is to be fitted with wood ceiling or insulation. If wood ceiling is fitted, the thickness is to comply with the requirements of 3.3.1.3 of this Section.

3.3.1.7 The covers or fittings of the manholes in cargo holds are, so far as practicable, not to project above the inner bottom plating or bottom ceiling; but if impracticable, they are to be protected by a steel coaming around each manhole, and such coamings together with wood ceiling or steel covers thereon are to be gradually sloped down to the flush surface of the inner bottom plating or bottom ceiling.

3.3.1.8 The external surface of tank top plating or shaft tunnel top plating covered by wood ceiling is to be coated with bituminous solution or other effective coating. Tank top plating and shaft tunnel top plating not covered by wood ceiling are to be coated with paints.

3.3.2 Cargo battens

3.3.2.1 Wood cargo battens are to be fitted at ship sides in cargo holds intended for the carriage of general cargoes. The clear space between adjacent rows of the cargo battens is not to exceed 300 mm, and the thickness and breadth of the cargo battens are to be determined in relation to the ship's length L as follows:

for $L \leq 60$ m, breadth not less than 100 mm, and thickness not less than 30 mm;

for 60 m $< L \leq$ 90m, breadth not less than 120 mm, and thickness not less than 40 mm;

for $L > 90$ m, breadth not less than 150 mm, and thickness not less than 50 mm.

Cargo battens may be made of steel.

Section 4 MASTS OR DERRICK POSTS

3.4.1 General requirements

3.4.1.1 Masts or derrick posts intended to support light derricks are to have at least two points of effective support. The superstructure deck with sufficient strength or the top of a substantial house may be used as one of the points of effective support.

3.4.1.2 Masts or derrick posts are to be effectively attached to the deck plating (at the point of support) where they pass through the deck, and the openings in the deck plating are to be effectively strengthened and compensated.

3.4.2 Wall thickness

3.4.2.1 The relative values between the outside diameter D and wall thickness t of the masts or derrick posts are to be in compliance with those given in the following formulae:

$$D \leq \frac{1000t}{25-t} \quad \text{mm} \quad \text{for } t \leq 15 \text{ mm}$$

$$D \leq 100t \quad \text{mm for } t > 15 \text{ mm}$$

3.4.2.2 The minimum wall thickness of masts or derrick posts is to be 6 mm; if the masts or derrick posts are used as ventilator pipes, the minimum wall thickness is not to be less than 7 mm.

3.4.3 Local strengthening

3.4.3.1 Masts or derrick posts intended to support light derricks are to be increased in thickness or doubled in plating, as appropriate, in way of the lower end, crosstrees, derrick seatings, and fixed eye plates for topping lifts or stays where concentrated loads may be expected to occur. Where strengthening is made by doubling plates, the depth and breadth of the doubling plates are to be slightly greater than those of the above fittings or the outside diameter of the masts or derrick posts in way, as appropriate.

3.4.3.2 The conditions and the factor of safety for strength calculations of masts or derrick posts are to comply with the requirements of the flag State Administration.

Section 5 EMERGENCY TOWING ARRANGEMENTS

3.5.1 Application

3.5.1.1 This Section applies to liquid cargo carriers of 20,000 tons deadweight and over, including oil tankers, chemical tankers and liquefied gas carriers, for being towed out of dangerous areas in emergency cases with the arrangements needed.

3.5.2 Class notations

3.5.2.1 Liquid cargo carriers fitted with emergency towing arrangements complying with this Section will be assigned the class notation of Emergency Towing Arrangements.

3.5.3 Plans and documents

3.5.3.1 The following plans and documents are to be submitted for approval:

(1) Details of emergency towing arrangements;

(2) Details of strongpoints and fairleads of emergency towing arrangements (related calculations are also to be submitted for information);

(3) Local structures supporting strongpoints and fairleads;

(4) Operation manual for emergency towing arrangements.

3.5.4 General requirements

3.5.4.1 The emergency towing arrangements are to be so designed that they are capable of easy operation and rapid connection to the towing vessel in the absence of main power of the ship.

3.5.4.2 The emergency towing arrangements are to be subject to approval by CCS and in accordance with the following requirements:

(1) The aft emergency towing arrangement is to be pre-rigged and capable of being deployed in harbour conditions in not more than 15 min.

(2) The pick-up gear for the aft towing pennant is to be designed at least for manual operation by one person taking into account the absence of power and the potential for adverse environmental conditions. The pick-up gear is to be protected against the weather and other adverse conditions.

(3) The forward emergency towing arrangement is to be designed at least with a means of securing a towline to the chafing gear using a suitably positioned pedestal roller to facilitate connection of the towing pennant.

(4) The forward emergency towing arrangement is to be capable of being deployed in harbour conditions in not more than 1 h.

(5) Forward emergency towing arrangements that comply with the requirements for aft emergency towing arrangements may be accepted.

(6) All emergency towing arrangements are to be clearly marked to facilitate safe and effective use even in darkness and poor visibility.

3.5.5 Arrangement and strength

3.5.5.1 typical details of emergency towing arrangements, see Figure 3.5.5.1.

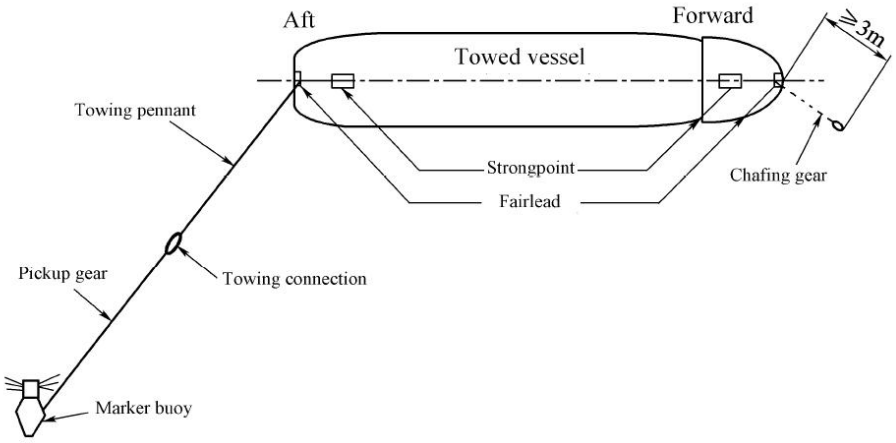

Figure 3.5.5.1 Typical Details of Emergency Towing Arrangements

The bow and stern strongpoint and fairleads are to be located so as to facilitate towing from either side of the bow or stern and minimize the stress on the towing system. Main components of towing arrangements are as shown in Table 3.5.5.1.

Major Components of Towing Arrangements **Table 3.5.5.1**

Major components	Location		Strength requirements
	Forward of ship	Aft of ship	
Pick-up gear	Optional	Yes	–
Towing pennant	Optional	Yes	Yes
Chafing gear	Yes	Depending on design	Yes
Fairlead	Yes	Yes	Yes
Strongpoint	Yes	Yes	Yes
Roller pedestal	Yes	Depending on design	–

3.5.5.2 The strength of towing arrangements is to be sufficient for all relevant angles of towline during towing operations, i.e. up to 90 ° from the ship's centreline to port and starboard and 30 ° vertical downwards. The safety factor of main components of towing arrangements is not to be less than 2. For safe working loads (SWL) of main components of towing arrangements, see Table 3.5.5.2.

Safe Working Load of Components **Table 3.5.5.2**

Deadweight of ship (t)	Safe working load (kN)
20000 to 50000	1000
≥ 50000	2000

3.5.6 Requirements for the arrangements and components

3.5.6.1 The towing pennant is to have a hard eye-formed termination allowing connection to a standard bow shackle. The towing pennant is to have a length of at least $2H$ + 50 m (H being the lightest seagoing ballast freeboard height at the fairlead, in m).

3.5.6.2 Different solutions on design of chafing gear may be used. If a chafing chain is used, the following requirements are to be complied with:

(1) the chafing chain is to be stud link chain and is to extend from the strongpoint to a point at least 3 m beyond the fairlead;

(2) one end of the chafing chain is to be suitable for connection to the strongpoint. The other end is to be fitted with a standard pear-shaped open link allowing connection to the towing pennant via a standard bow shackle. A typical outboard chafing chain end and a pear-shaped open link are shown in Figure 3.5.6.2(2);

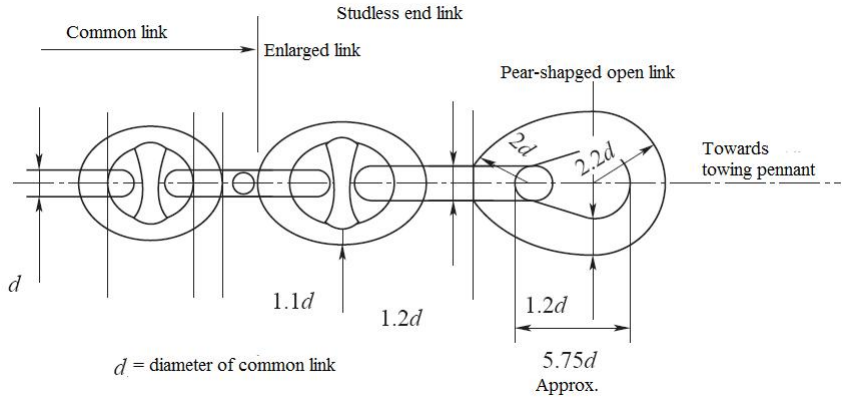

Figure 3.5.6.2(2) Typical Outboard Chafing Chain End

(3) in addition to this Section, the chafing chain is to be designed, manufactured, tested and certified in accordance with the relevant requirements of Section 2, Chapter 10 of PART ONE of CCS Rules for Materials and Welding;

(4) chafing chains are to be made of M2 or M3 chain steel by manufacturers approved by CCS;

(5) the nominal diameter of common links for chafing chains is to comply with the values indicated in Table 3.5.6.2(5) and the nominal diameter of other links are to be determined according to Figure 3.5.6.2(2);

(6) the chafing chain is to be stowed in such a way that it can be rapidly connected to the strongpoint.

Minimum Nominal Diameter of Common Link **Table 3.5.6.2(5)**

Type of emergency towing arrangement (ETA)	Minimum nominal diameter of common link d	
	Grade 2	Grade 3
ETA1000	62 mm	52 mm
ETA2000	90 mm	76 mm

3.5.6.3 The fairleads may be mooring fairleads or fairleads with cable rollers. Fairleads are to have an opening large enough to pass the largest portion of the chafing gear, towing pennant and associated components. The recommended size of such openings is 450 mm × 600 mm. The fairlead is to be located as close as possible to the deck and, in any case, in such a position that the chafing chain is approximately parallel to the deck when it is under strain between the strongpoint and the fairlead. The fairlead is to have an adequate bearing surface, and the bending ratio (towing pennant bearing surface diameter to towing pennant diameter) is not to be less than 7:1.
3.5.6.4 The strongpoint is the inboard end fastening of the towing arrangement and is to be a stopper or bracket or other fitting of equivalent strength. The strongpoint may be designed integral with the fairlead.

Section 6 SHIPBOARD FITTINGS AND SUPPORTING HULL STRUCTURES ASSOCIATED WITH TOWING AND MOORING ON CONVENTIONAL VESSELS

3.6.1 General requirements

3.6.1.1 This Section applies to design and construction of shipboard fittings and supporting structures used for the normal towing and mooring operations.
3.6.1.2 The minimum net scantlings of the supporting hull structure are to comply with the requirements given in 3.6.3.5 and 3.6.4.5 of this Section. The net thicknesses, t_{net}, are the member thicknesses necessary to obtain the above required minimum net scantlings. The required gross thicknesses are obtained by adding the total corrosion additions, t_c, given in 3.6.6 of this Section, to t_{net}.
3.6.1.3 This Section applies to ships the contract of which is placed on or after 1 July 2018.
3.6.1.4 This Section is not applicable to escort towing, canal transit towing and emergency towing for tankers.

3.6.2 Definitions

3.6.2.1 Conventional vessels mean new displacement-type vessels of 500 GT and above, excluding high speed craft, special purpose vessels, and offshore units of all types. Special purpose ship means a mechanically self-propelled ship which by reason of its function carries on board more than 12 special personnel.
3.6.2.2 Shipboard fittings mean those components limited to the following: bollards and bitts, fairleads, stand rollers, chocks used for the normal mooring of the vessel and the similar components used for the normal towing or other towing of the vessel. Other components such as capstans, winches, etc. are not covered by this Section. Any weld or bolt or equivalent device connecting the shipboard fitting to the supporting structure is part of the shipboard fitting and if selected from an industry standard subject to that standard.
3.6.2.3 Supporting hull structures mean that part of the ship structure on/in which the shipboard fitting is placed and which is directly submitted to the forces exerted on the shipboard fitting. The supporting hull structure of capstans, winches, etc. used for the normal towing or other towing and mooring operations mentioned above is also subject to this Section.
3.6.2.4 Industry standard means international standard (ISO, etc.) or standards issued by national association which are recognized in the country where the ship is built.
3.6.2.5 Normal towing means towing operations necessary for manoeuvring in ports and sheltered waters associated with the normal operations of the ship.
3.6.2.6 Other towing means for ships, not subject to Section 5 of this Chapter, but intended to be fitted with equipment for towing by another ship or a tug, e.g. such as to assist the ship in case of emergency.
3.6.2.7 Escort towing means towing service, in particular, for laden oil tankers or LNG carriers, required in specific estuaries. Its main purpose is to control the ship in case of failures of the propulsion or steering system.
3.6.2.8 Canal transit towing means towing service for ships transiting canals.
3.6.2.9 Emergency towing for tankers means towing service to assist tankers in case of emergency, see Section 5 of this Chapter.
3.6.2.10 The nominal capacity condition is defined as the theoretical condition where the maximum possible deck cargoes are included in the ship arrangement in their respective positions. For container ships the nominal capacity condition represents the theoretical condition where the maximum possible number of containers is included in the ship arrangement in their respective positions.

3.6.2.11 Ship Design Minimum Breaking Load (MBLSD) means the minimum breaking load of new, dry mooring lines or tow line for which shipboard fittings and supporting hull structures are designed in order to meet mooring restraint requirements or the towing requirements of other towing service.
3.6.2.12 Line Design Break Force (LDBF) means the minimum force that a new, dry, spliced, mooring line will break at. This is for all synthetic cordage materials.

3.6.3 Towing

3.6.3.1 The strength of shipboard fittings used for normal towing or other towing operations at bow, sides and stern and their supporting hull structures are to comply with the requirements of 3.6.3.2 to 3.6.3.6 of this Section. For fittings intended to be used for, both, towing and mooring, 3.6.4 applies to mooring.
3.6.3.2 Shipboard fittings for towing are to be located on stiffeners and/or girders, which are part of the deck construction so as to facilitate efficient distribution of the towing load. Other arrangements may be accepted (for chocks in bulwarks, etc.) provided the strength is confirmed adequate for the intended service.
3.6.3.3 Load considerations
The minimum design load applied to supporting hull structures for shipboard fittings is to be:
(1) For normal towing operations, 1.25 times the intended maximum towing load (e.g. static bollard pull) as indicated on the towing and mooring arrangements plan.
(2) For other towing service, the ship design minimum breaking load of the towline corresponding to equipment no. *N* in Table 3.2.1.1(2) is to be applied.
Note: Side projected area including that of deck cargoes as given by the ship nominal capacity condition is to be taken into account for selection of towing lines and the breaking loads of towing lines are used as the design loads.
(3) For fittings intended to be used for, both, normal and other towing operations, the greater of the design loads according to (1) and (2).
(4) When a safe towing load TOW greater than that determined according to 3.6.3.6 is requested by the applicant, then the design load is to be increased in accordance with the appropriate TOW/design load relationship.
(5) The design load is to be applied to fittings in all directions that may occur by taking into account the arrangement shown on the towing and mooring arrangements plan. Where the towing line takes a turn at a fitting the total design load applied to the fitting is equal to the resultant of the design loads acting on the line, however, the load need not be more than twice the design load.

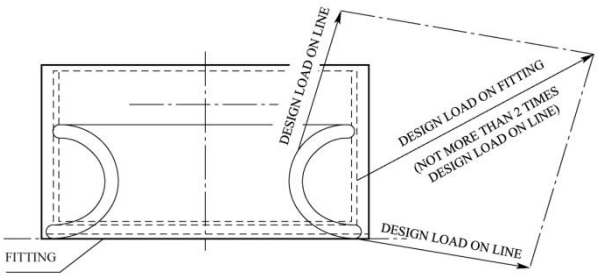

Figure 3.6.3.3(5)

3.6.3.4 Shipboard fittings may be selected from an accepted industry standard and at least based on the following loads.
(1) For normal towing operations, the intended towing load (e.g. static bollard pull) as indicated on the towing and mooring arrangements plan,
(2) For other towing service, the ship design minimum breaking load of the tow line according to Table 3.2.1.1(2) (see Notes in 3.6.3.3(2)),
(3) For fittings intended to be used for, both, normal and other towing operations, the greater of the loads according to (1) and (2).
Towing bitts (double bollards) may be chosen for the towing line attached with eye splice if the industry standard distinguishes between different methods to attach the line, i.e. figure-of-eight or eye splice attachment.
When the shipboard fitting is not selected from an accepted Industry standard, the design load used to assess its strength and its attachment to the ship is to be in accordance with 3.6.3.3 and 3.6.3.5. Towing bitts (double bollards) are required to resist the loads caused by the towing line attached with eye splice.

For strength assessment beam theory or finite element analysis using net scantlings is to be applied, as appropriate. Corrosion additions are to be as defined in 3.6.6. A wear down allowance is to be included as defined in 3.6.7. At the discretion of the Society, load tests may be accepted as alternative to strength assessment by calculations.

3.6.3.5 Supporting hull structure

(1) Arrangement:

The reinforced members beneath shipboard fittings are to be effectively arranged for any variation of direction (horizontally and vertically) of the towing forces acting upon the shipboard fittings, see Figure 3.6.3.5(1) below for a sample arrangement. Proper alignment of fitting and supporting hull structure is to be ensured.

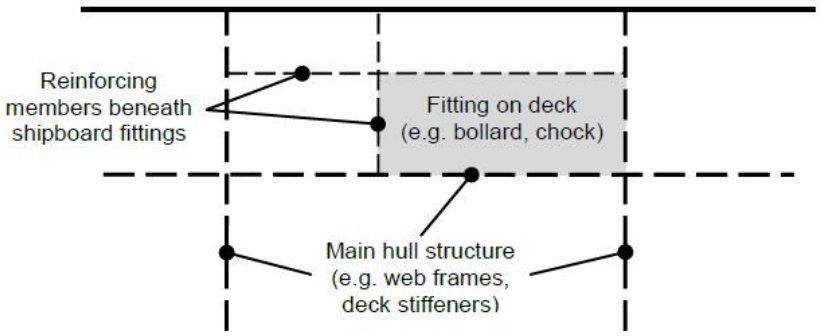

Figure 3.6.3.5(1)

(2) Acting point of towing force:

The acting point of the towing force on shipboard fittings is to be taken at the attachment point of a towing line or at a change in its direction. For bollards and bitts the attachment point of the towing line is to be taken not less than 4/5 of the tube height above the base, see Figure 3.6.3.5(2).

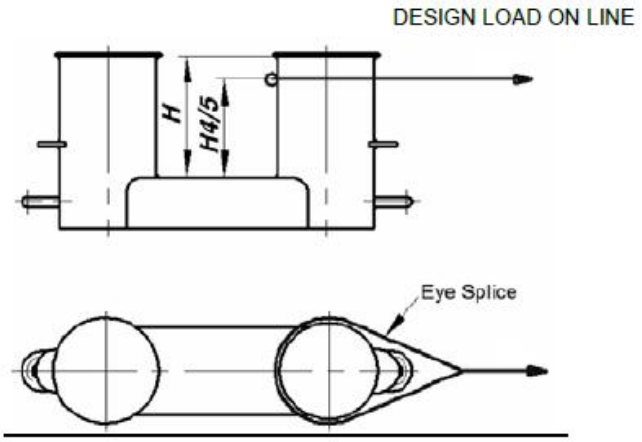

Figure 3.6.3.5(2)

(3) Allowable stresses:

Allowable stresses under the design load conditions as specified in 3.6.3.3 of this Section are as follows:

1) For strength assessment with beam theory or grillage analysis:

Normal stress: $1.0R_{eH}$;

Shearing stress: $0.6R_{eH}$;

Normal stress is the sum of bending stress and axial stress with the corresponding shearing stress acting perpendicular to the normal stress. No stress concentration factors being taken into account.

(2) For strength assessment with finite element analysis:

Von Mises stress: $1.0R_{eH}$.

For strength calculations by means of finite elements, the geometry is to be idealized as realistically as possible. The ratio of element length to width is not to exceed 3. Girders are to be modelled using shell or plane stress elements. Symmetric girder flanges may be modelled by beam or truss elements. The element height of girder webs must not exceed one-third of the web height. In way of small openings in girder webs

the web thickness is to be reduced to a mean thickness over the web height. Large openings are to be modelled. Stiffeners may be modelled by using shell, plane stress, or beam elements. The mesh size of stiffeners is to be fine enough to obtain proper bending stress. If flat bars are modeled using shell or plane stress elements, dummy rod elements are to be modelled at the free edge of the flat bars and the stresses of the dummy elements are to be evaluated. Stresses are to be read from the centre of the individual element. For shell elements the stresses are to be evaluated at the mid plane of the element.
R_{eH} is the specified minimum yield stress of the material.

3.6.3.6 Safe Towing Load (TOW)

(1) The safe towing load (TOW) is the safe load limit of shipboard fittings used for towing purpose.

(2) TOW used for normal towing operations is not to exceed 80% of the design load per 3.6.3.3 (1).

(3) TOW used for other towing operations is not to exceed 80% of the design load according to 3.6.3.3 (2).

(4) For fittings used for both normal and other towing operations, the greater of the safe towing loads according to (2) and (3) is to be used.

(5) TOW, in t, of each shipboard fitting is to be marked (by weld bead or equivalent) on the deck fittings used for towing. For fittings intended to be used for, both, towing and mooring, SWL, in t, according to 3.6.4.6 is to be marked in addition to TOW.

(6) The above requirements on TOW apply for the use with no more than one line. If not otherwise chosen, for towing bitts (double bollards) TOW is the load limit for a towing line attached with eye-splice.

(7) The towing and mooring arrangements plan mentioned in 3.6.5 is to define the method of use of towing lines.

3.6.4 Mooring

3.6.4.1 The strength of shipboard fittings used for mooring operations and of their supporting hull structures as well as the strength of supporting hull structures of winches and capstans is to comply with the requirements of 3.6.4.2 to 3.6.4.6 of this Section.

3.6.4.2 Shipboard fittings, winches and capstans for mooring are to be located on stiffeners and/or girders, which are part of the deck construction so as to facilitate efficient distribution of the mooring load. Other arrangements may be accepted (for chocks in bulwarks, etc.) provided the strength is confirmed adequate for the service. For fittings intended to be used for, both, mooring and towing, 3.6.3 applies to towing.

3.6.4.3 Load considerations

(1) The minimum design load applied to supporting hull structures for shipboard fittings is to be 1.15 times the ship design minimum breaking strength of the mooring line according to 3.2.4 of this Chapter.

Note: Side projected area including that of deck cargoes as given by the ship nominal capacity condition is to be taken into account for assessment of transverse wind load, tug arrangement and selection of mooring lines.

(2) The minimum design load applied to supporting hull structures for winches is to be 1.25 times the intended maximum brake holding load, where the maximum brake holding load is to be assumed not less than 80% of the ship design minimum breaking strength of the mooring line according to 3.2.4 of this Chapter. For supporting hull structures of capstans, 1.25 times the maximum hauling-in force is to be taken as design load.

(3) When a safe working load SWL greater than that determined according to 3.6.4.6 is requested by the applicant, then the design load is to be increased in accordance with the appropriate SWL/design load relationship.

(4) The design load is to be applied to fittings in all directions that may occur by taking into account the arrangement shown on the towing and mooring arrangements plan. Where the mooring line takes a turn at a fitting the total design load applied to the fitting is equal to the resultant of the design loads acting on the line, refer to Figure 3.6.3.3(5). However, in no case does the design load applied to the fitting need to be greater than twice the design load on the line.

3.6.4.4 Shipboard fittings may be selected from an accepted industry standard and at least based on the ship design minimum breaking strength according to 3.2.4 of this Chapter.

Mooring bitts (double bollards) are to be chosen for the mooring line attached in figure-of-eight fashion if the industry standard distinguishes between different methods to attach the line, i.e. figure-of-eight or eye splice attachment.

When the shipboard fitting is not selected from an accepted Industry standard, the design load used to assess its strength and its attachment to the ship is to be in accordance with 3.6.4.3 and 3.6.4.5 of this Section. Mooring bitts (double bollards) are required to resist the loads caused by the mooring line attached in figure-of-eight fashion. It is to be observed that in this case either of the two posts of the mooring bitt can be subjected to a force twice as large as that acting on the mooring line. For strength assessment beam theory or finite element analysis using net scantlings is to be applied, as appropriate. Corrosion additions are to be as defined in 3.6.6. A wear down allowance is to be included as defined in 3.6.7. At the discretion

of the classification society, load tests may be accepted as alternative to strength assessment by calculations.

3.6.4.5 Supporting hull structure

(1) Arrangement:

Arrangement of the reinforced members beneath shipboard fittings is to consider any variation of direction (horizontally and vertically) of the mooring forces acting upon the shipboard fittings, see Figure 3.6.3.5(1) for a sample arrangement. Proper alignment of fitting and supporting hull structure is to be ensured.

(2) Acting point of mooring force:

The acting point of the mooring force on shipboard fittings is to be taken at the attachment point of a mooring line or at a change in its direction. For bollards and bitts the attachment point of the mooring line is to be taken not less than 4/5 of the tube height above the base, see a) in Figure 3.6.4.5(2) a). If fins are fitted to the bollard tubes to keep the mooring line as low as possible, the attachment point of the mooring line may be taken at the location of the fins, see Figure 3.6.4.5(2) b).

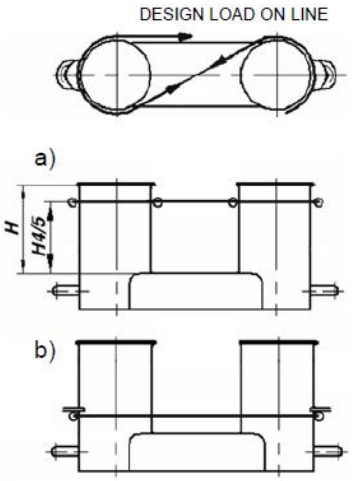

Figure 3.6.4.5(2)

(3) Allowable stresses:

Allowable stresses under the design load conditions as specified in 3.6.4.3 of this Section are as follows:

1) For strength assessment with beam theory or grillage analysis:

Normal stress: $1.0R_{eH}$;

Shearing stress: $0.6R_{eH}$;

Normal stress is the sum of bending stress and axial stress with the corresponding shearing stress acting perpendicular to the normal stress. No stress concentration factors being taken into account.

2) For strength assessment with finite element analysis:

Von Mises stress: $1.0R_{eH}$.

For strength calculations by means of finite elements, the geometry is to be idealized as realistically as possible. The ratio of element length to width is not to exceed 3. Girders are to be modelled using shell or plane stress elements. Symmetric girder flanges may be modelled by beam or truss elements. The element height of girder webs must not exceed one-third of the web height. In way of small openings in girder webs the web thickness is to be reduced to a mean thickness over the web height. Large openings are to be modelled. Stiffeners may be modelled by using shell, plane stress, or beam elements.The mesh size of stiffeners is to be fine enough to obtain proper bending stress. If flat bars are modeled using shell or plane stress elements, dummy rod elements are to be modelled at the free edge of the flat bars and the stresses of the dummy elements are to be evaluated. Stresses are to be read from the centre of the individual element. For shell elements the stresses are to be evaluated at the mid plane of the element.

3.6.4.6 Safe Working Load (SWL)

(1) The Safe Working Load (SWL) is the safe load limit of shipboard fittings used for mooring purpose.

(2) Unless a greater SWL is requested by the applicant according to 3.6.4.3(3), the SWL is not to exceed the ship design minimum breaking strength according to 3.2.4 of this Chapter.

(3) The SWL, in t, of each shipboard fitting is to be marked (by weld bead or equivalent) on the deck fittings used for mooring. For fittings intended to be used for, both, mooring and towing, TOW, in t, according to 3.6.3.6 is to be marked in addition to SWL.

(4) The above requirements on SWL apply for the use with no more than one mooring line.
(5) The towing and mooring arrangements plan mentioned in 3.6.5 is to define the method of use of mooring lines.

3.6.5 Towing and mooring arrangements plan

(1) The SWL and TOW for the intended use for each shipboard fitting is to be noted in the towing and mooring arrangements plan available on board for the guidance of the Master. It is to be noted that TOW is the load limit for towing purpose and SWL that for mooring purpose. If not otherwise chosen, for towing bitts it is to be noted that TOW is the load limit for a towing line attached with eye-splice.
(2) Information provided on the plan is to include in respect of each shipboard fitting:
1) location on the ship;
2) fitting type;
3) SWL/TOW;
4) purpose (mooring/harbour towing/other towing); and
5) manner of applying towing or mooring line load including limiting fleet angles i.e. angle of change in direction of a line at the fitting.
The purposes and method for applying loads are to be taken into account in the determination of SWL and TOW of fittings and submitted for approval.
Furthermore, information provided on the plan is to include:
1) the arrangement of mooring lines showing number of lines (N);
2) the ship design minimum breaking load (MBL_{SD});
3) the acceptable environmental conditions for ship design minimum breaking load for ships with Equipment Number EN > 2000, including 30 second mean wind speed from any direction and maximum current speed acting on bow or stern (±10°).
(3) The information as given in (2) is to be incorporated into the pilot card in order to provide the pilot proper information on harbour/other towing operations.

3.6.6 Corrosion addition

The total corrosion addition, t_c, in mm, is not to be less than the following values:
(1) For the supporting hull structure, 2 mm;
(2) For pedestals and foundations on deck which are not part of a fitting according to an accepted industry standard, 2.0 mm.
(3) For shipboard fittings not selected from an accepted industry standard, 2.0 mm.

3.6.7 Wear allowance

In addition to the corrosion addition given in 3.6.6 the wear allowance, tw, for shipboard fittings not selected from an accepted industry standard is not to be less than 1.0 mm, added to surfaces which are intended to regularly contact the line.

3.6.8 Survey after construction

The condition of deck fittings, their pedestals or foundations, if any, and the hull structures in the vicinity of the fittings are to be examined in accordance with the Rules.

Section 7 SUPPORT STRUCTURE FOR DECK EQUIPMENT

3.7.1 General requirements

3.7.1.1 Information pertaining to the support structure of deck equipment and fittings, as listed in 3.7.1.2(1) to (5) of this Section, is to be submitted for approval. Support structure means that part of the ship structure on/in which deck equipment and fittings are placed and which is directly subjected to the forces acting on the deck equipment and fittings.
3.7.1.2 This Section includes scantling requirements for the support structure and foundations of the following pieces of equipment and fittings:
(1) anchor windlasses;
(2) anchoring chain stoppers;
(3) deck cranes, derricks and lifting masts;
(4) emergency towing arrangements;
(5) other deck equipment and fittings which are subject to specific approval.

3.7.1.3 Where deck equipment is subject to multiple load cases, such as an operational load and a green seas load, the operational load and green seas load are be applied independently for the evaluation of strength of foundations and support structure. Loads are to be applied in the direction of the anchor chain.

3.7.2 Supporting structures for anchoring windlass and chain stopper

3.7.2.1 The following plans and information are to be submitted for approval:
(1) Details of the supporting structure for the anchor windlass;
(2) Details of the windlass foundation design, including material specifications for holding down bolts and the connection of the foundation to the deck;
(3) Details of the chain stopper foundation design, including material specification and the connection of the foundation to the deck.
3.7.2.2 The following plans and information are also to be submitted:
(1) General arrangement drawing of anchoring equipment;
(2) Design loads as specified in 3.7.2.3 and 3.7.2.4 of this Section and associated reaction forces applied to the foundation and supporting structure.
3.7.2.3 The following load cases are to be examined for the strength of supporting structures of windlasses and chain stoppers:
(1) windlass where chain stopper is provided: 45% of breaking load;
(2) windlass where chain stopper is not provided: 80% of breaking load;
(3) chain stopper: 80% of breaking load.
The breaking load is the minimum breaking load of chain as defined according to Table 3.2.1.1(2) of this Chapter. The loads are to be applied in the direction of chain.
3.7.2.4 For windlasses complying with the requirements of 3.2.5.1 of this Chapter, the strength of securing of windlasses on fore deck is also to be checked in accordance with the requirements of 3.2.5 of this Chapter.
3.7.2.5 When checking the strength of supporting structures and foundations, a three-dimensional finite element model is to be applied as far as possible in the analysis to more exactly describe the distribution of structural response in all directions. Where a beam system is or plate girders are used, the model is to be reasonably simplified and be more conservative. The analysis is to be based on the theory of linear elasticity. The thicknesses of structural members in the model are net ones. Corrosion allowance is in accordance with 1.6.5, Section 5, Chapter 1 of this PART.
3.7.2.6 The principles for extent, element types and boundary conditions of a three-dimensional model are as follows:
(1) Extent and boundary conditions: The structural model is a local three-dimensional one (hereinafter referred to as local model), centred on the centroid of a plane rectangle ($a \times b$) for effects of the foundation and extending outwards for a distance respectively at least one time the length and width corresponding to the rectangle ($3a \times 3b$). This extension reaches vertically from the foundation plane to the first platform (deck) under main deck or at least $D/4$ (D being moulded depth). Where there is no primary support member of the structure at the boundary taken in the above way, the model is to further extend until the boundary is at such support member. Free or fixed support may be taken into account for boundary conditions. Where the boundary conditions or the extent of the model is sensitive to calculation results of the centre area, the extent taken for the local model is to be suitably extended again, provided that calculation results of the centre area will not be affected.
(2) Idealization of local model: The principles for element selection, properties and model meshing etc. are as given in 1.5.6, Section 5, Chapter 1 of this PART.
(1) 3.7.2.7 For all loading conditions, the stresses taken in calculation for supporting structures and foundations are not to exceed the following permissible values:For strength assessment by means of beam theory or grillage analysis:
Normal stress: 1.0 R_{eH}
Shear stress: 0.6 R_{eH}
The normal stress is the sum of bending stress and axial stress. The shear stress to be considered corresponds to the shear stress acting perpendicular to the normal stress. No stress concentration factors are to be taken into account.
(2) For strength assessment by means of finite element analysis:
Von Mises stress: 1.0 R_{eH}
For strength assessment by means of finite element analysis the mesh is to be fine enough to represent the geometry as realistically as possible. The aspect ratios of elements are not to exceed 3. Girders are to be modelled using shell or plane stress elements. Symmetric girder flanges may be modelled by beam or truss elements. The element height of girder webs must not exceed one-third of the web height. In way of small

openings in girder webs, the web thickness is to be reduced to a mean thickness over the web height. Large openings are to be modelled. Stiffeners may be modelled using shell, plane stress, or beam elements. The mesh size of stiffeners is to be fine enough to obtain proper bending stress. If flat bars are modeled using shell or plane stress elements, dummy rod elements are to be modelled at the free edge of the flat bars and the stresses of the dummy elements are to be evaluated. Stresses are to be read from the centre of the individual element. For shell elements the stresses are to be evaluated at the mid plane of the element.
R_{eH} is the specified minimum yield stress of the material.

3.7.3 Supporting structure for cranes, derricks and lifting masts

3.7.3.1 The supporting structures of lifting appliances which are identified as basic features of the ship, such as lifting appliances of floating crane and submersible handling system of submersible supply vessel are to comply with the requirements of CCS Rules for Lifting Appliances of Ships and Offshore Installations.
The supporting structures of other lifting appliances, including cranes, derricks and lifting masts with a safe working load greater than 30 kN, or a maximum overturning moment to the supporting structure greater than 100 kN·m, are to comply with the requirements of this Section.
3.7.3.2 These requirements do not cover the following items:
(1) supports of lifting appliances for personnel or passengers, see 3.7.5.2 of this Section;
(2) the structure of the lifting appliance pedestals or post above the area of the deck connection;
(3) holding down bolts and their arrangement, which are considered part of the lifting appliance.
3.7.3.3 The term lifting appliance is defined as a crane, derrick or lifting mast.
3.7.3.4 The safe working load is defined as the maximum load which the lifting appliance is certified to lift at any specified outreach.
3.7.3.5 The self-weight is the calculated gross self-weight of the lifting appliance, including the weight of any lifting gear.
3.7.3.6 The overturning moment is the maximum bending moment, calculated at the connection of the lifting appliance to the ship structure, due to the lifting appliance operating at safe working load, taking into account outreach and self-weight.
3.7.3.7 The following plans and information are to be submitted for approval:
(1) Details of the supporting structure of the lifting appliance, including its connection of the deck;
(2) Details of the safe working load, self-weight, vertical reaction forces and the maximum overturning moment in the supporting structure of the lifting appliance;
(3) For offshore operation, the maximum sea state in which the lifting appliance is to be used.
3.7.3.8 The general arrangement drawing of the crane/derrick/lifting mast is also to be submitted.
3.7.3.9 For lifting appliances which are limited to use in harbour, the load cases to be examined are to include 130% of the safe working load added to the lifting appliances self-weight.
3.7.3.10 For lifting appliances which may be used for offshore (refers to open waters, the sea condition of which will cause significant motion of the ship, and the wind force at sea normally exceeds Beaufort scale 2) operations, the following are to be submitted for approval:
(1) The maximum sea state in which the lifting appliance is to be used;
(2) The worst case vertical and horizontal accelerations;
(3) The worst case wind loadings for the specified design sea state and wind environment.
(4) The load scenario to be examined is to account for these environmental loads. As a minimum, the 150% of the safe working load added to the lifting appliances self-weight is to be examined.
3.7.3.11 For calculation and analysis requirements and modeling method, refer to 3.7.2.5 and 3.7.2.6 of this Section. The thicknesses of structural members in the model are as built ones.
3.7.3.12 In all conditions, the stresses taken in calculation for the supporting structures and foundations of lifting appliances are not to exceed the permissible values as follows:
(1) Strength assessment by means of beam theory or grillage analysis:

Direct stress: $0.67R_{eH}$

Shear stress:$0.39R_{eH}$

Direct stress means the sum of bending stress and axial stress, with the corresponding shear stress acting perpendicular to the direct stress. Stress concentration factors are not considered.
(2) Strength assessment by means of FE analysis method:

Von Mises stress: $0.80R_{eH}$

R_{eH} is specified minimum yield stress of material, in N/mm^2.
3.7.3.13 In addition to the requirement of 3.7.3.12 of this Section, the capability of the supporting structure to resist buckling failure is to be checked according to the requirements of 1.5.9, Section 5,

Chapter 1 of this PART. In buckling strength assessment, the standard thickness deduction of structural members is to be taken as 1.0 mm and the minimum buckling safety factor taken as 1.0.

3.7.4 Supporting structures for components used in emergency towing arrangements

3.7.4.1 Tankers (including oil tankers, chemical tankers and liquefied gas carriers) carrying flammable liquid cargoes in bulk, having a deadweight of not less than 20,000 tonnes are to be fitted with an emergency towing arrangement at both fore and aft ends.

3.7.4.2 The safe working load of emergency towing arrangements is as follows:

(1) 1,000 kN for vessels having a deadweight greater than or equal to 20,000 tonnes, but less than 50,000 tonnes;

(2) 2,000 kN for vessels having a deadweight greater than or equal to 50,000 tonnes.

3.7.4.3 The following plans are to be submitted for approval:

Details of the supporting structure for the emergency towing arrangement, including the connection to the deck.

3.7.4.4 The following supporting information is also to be submitted:

Details of the emergency towing arrangement showing sufficient detail to enable the position and direction of load actions to be ascertained.

3.7.4.5 The deck in way of strongpoints and fairleads is to have a minimum gross thickness of 15 mm.

3.7.4.6 The design load for the connection of the strongpoint and fittings to the deck and its supporting structure is to be taken as twice the safe working load. The assessment of the structure is to consider lines of action of the applied design load, taking into account the particular arrangements proposed.

3.7.4.7 For calculation and analysis requirements and modeling method, refer to 3.7.2.5 and 3.7.2.6 of this Section. The thicknesses of structural members in the model are as built ones.

3.7.4.8 For the design load specified in 3.7.4.6 of this Section, the stresses induced in the supporting structure and welds, in way of strongpoints and fairleads, are not to exceed the permissible values given in 3.7.2.7 of this Section.

3.7.4.9 The capability of the structure to resist buckling failure is also to be assured.

3.7.5 Supporting structures for other deck equipment or fittings which are subject to specific approval

3.7.5.1 The following requirements relate to other items of deck equipment which are not covered by 3.7.2 to 3.7.4 of this Section. The following details are to be submitted for approval. They may be indicated separately or may be included on the main structural drawings:

(1) Plans showing the supporting structure for deck equipment/fittings;

(2) Details of the loads imposed on the structure by the deck equipment/fittings.

3.7.5.2 Support for lifting appliances for personnel is to be provided as follows:

(1) in general, lifesaving appliances (lifeboats, life rafts and rescue boats) are to be stowed on a purpose built cradle, seat or deployment appliance. The design load imposed on the ship structure is to be established by the supplier of the lifesaving appliance (to include 2.2 times of bearing reaction and torque under maximum working load as a minimum). For calculation and analysis requirements and modeling method, refer to 3.7.2.5 and 3.7.2.6 of this Section. The thicknesses of structural members in the model are as built ones. The calculated stresses are not to exceed the permissible values given in Table 3.7.3.12. The supplier of the life-saving appliance is to provide corresponding calculation information;

(2) the support structure is to be adequate for the design loads. Local stiffening and a local increase in plating thickness is to be provided. Primary supporting members may be required. Additional national and international Regulations are to be applied, where applicable;

(3) support structure for crew lifts is to be provided in way of the anchor points of lift operating equipment;

(4) support structure for boarding (accommodation) ladders is to be provided in way of the anchor points of accommodation ladders.

3.7.5.3 Support for mast structures fitted with navigation aids is to be provided as follows:

(1) adequate primary support members for the mast are to be arranged in the form of bulkheads, deep beams or girders. Such members are to be arranged below or close to the mast structure;

(2) in order to transmit the loads from the mast structure to the primary supporting members, underdeck stiffening members are to be arranged below the mast structure forming the attachment of the mast to the deck;

(3) the deck thickness may be required to be increased to provide an adequate thickness for the weld attachments.

3.7.5.4 Supporting structure for breakwaters is to be designed to withstand the same design load as the breakwater itself. It is to be suitable for transmitting the loads from the breakwater into the main supporting

members of the ship. Efficient underdeck stiffening is to be provided in way of the breakwater structure that forms the deck connection.

3.7.5.5 The supporting structure of towing arrangements of tugs are to comply with the requirements of 10.5.3, Section 5 of Chapter 10 of this PART.

Section 8 ENERGY-SAVING APPENDAGES IN FRONT OF PROPELLERS

3.8.1 General

3.8.1.1 The provisions in this Section is optional and apply to energy-saving appendages installed onboard in front of propellers. Ships applying for notation PSD are to comply with the provisions of this Chapter.

3.8.1.2 Appropriate vibration evaluation and control are recommended in the design and installation of energy-saving appendages in front of propellers. In general, the natural frequency of the energy-saving appendage and propeller excitation frequency are at least to guarantee 10% of the frequency reserve.

3.8.2 Plans and documents

3.8.2.1 The following plans and documents are to be submitted for approval. Where they are already included in the plans and documents required to be submitted for the ship, there is no need to submit them repeatedly:

(1) Structural plan for the energy-saving appendage in front of the propeller.

3.8.2.2 The following plans and documents are to be submitted for information:

(1) Arrangement for the energy-saving appendage in front of the propeller;

(2) Profile for energy-saving appendages in front of the propeller (where applicable);

(3) Structural strength calculation report (including loads for calculation) for the energy-saving appendage in front of the propeller;

(4) Vibration frequency calculation report for the energy-saving appendage in front of the propeller.

3.8.3 Structural strength assessment

3.8.3.1 Structural strength calculation analysis is to be carried out for the energy-saving appendage in front of the propeller. Structural strength analysis for various conditions is to be carried out considering possible loads on the energy-saving appendage in front of the propeller in actual operation.

3.8.3.2 Explanatory notes to the calculation model:

(1) Local three-dimensional structure model is generally used in modeling and analysis of the energy-saving appendage structure to reasonably simulate their shapes;

(2) The general principles for element selection, characteristics and meshing of the energy-saving appendage structure model are to be in accordance with the requirements of 1.5.6, Section 5, Chapter 1, PART TWO of the Rules. In order to better simulate its shape, the calculation model is to adopt appropriate element mesh size, which is recommended not to exceed 200 mm×200 mm.

3.8.3.3 The extent and boundary conditions of the model are as follows:

(1) For the calculation model, the longitudinal extent is generally to include the entire energy-saving appendage in front of the propeller and extends to the aft end wall of the hull engine room; the vertical extent is from the baseline up to the first platform structure near the standard height above the propeller centerline, where the standard height is 1.5 times the distance between the propeller centerline and the highest point of the energy-saving appendage in front of the propeller;

(2) The assumption of boundary conditions is to be based on the principle of not affecting the calculation results of the energy-saving appendage in front of the propeller and its reinforcement structure. Generally free support or fixed support is provided.

3.8.3.4 The loads on the energy-saving appendage in front of the propeller may be obtained from hydrodynamic calculation or model test or obtained as follows; the following loads are to be included as a minimum:

(1) the hydrodynamic wave pressure, calculated according to 1.5.3.3(4), Section 5, Chapter 1, PART TWO of the Rules;

(2) Inertia force of ship motion, calculated according to 1.5.2.2, Section 5, Chapter 1, PART TWO of the Rules;

(3) Lateral rotating force, calculated according to 3.1.2.1(1), Section 1, Chapter 3, PART TWO of the Rules.

3.8.3.5 The calculation conditions are to include the most unfavorable stress condition of the energy-saving appendage structure in front of the propeller, or they can be selected according to experience and actual operation situation, and are to include the following conditions as a minimum:
(1) navigation condition: inertia force of ship motion + hydrostatic pressure + hydrodynamic wave pressure (the wave direction is same as the navigation direction);
(2) rotating condition: inertia force of ship motion + hydrostatic pressure + lateral rotating force.
3.8.3.6 See Table 3.8.3.6 for permissible stress.

Permissible stress **Table 3.8.3.6**

Type of element	Permissible stress
Plate element	$[\sigma_e]=0.5R_{eH}$

Note: R_{eH}—yield stress of material, in N/mm^2.

3.8.4 Welding

3.8.4.1 The steels used in weldment of the energy-saving appendage in front of the propeller are to comply with the relevant provisions in Chapters 3, 5 and 6, PART ONE of CCS Rules for Materials and Welding for hull structural steels, steel forgings, steel castings respectively. Alternative materials may be adopted subject to CCS agreement.
3.8.4.2 Welding is to be performed by welders approved by CCS using welding consumables approved by CCS according to welding procedures approved by CCS. For relevant requirements, see Chapters 2, 3, 4 and 5, PART THREE of CCS Rules for Materials and Welding.
3.8.4.3 The fillet welds inside the energy-saving appendage in front of the propeller are generally to be continuous at both sides and the welding coefficient is to be taken as 0.2. When the surface shell cannot be connected to the internal web by fillet welds directly, a flat bar may be lined between the surface shell and the web. The surface shell and the flat bar can be connected by plug welding and the welding coefficient is to be taken as 0.44, or a groove can be opened on the surface shell, and the flat bar can be butt welded as a liner. Alternatively, other CCS approved welding connection methods may be adopted.
3.8.4.4 As shown in Figure 3.8.4.4, the fillet welds of the connection between the energy-saving appendage in front of the propeller (including the external supporting structure) and the hull as well as the fillet welds of the connection between the guide wheel and guide vane are to be full penetration fillet welds. Where welding at both sides is not possible, single-sided groove can be opened and welded with steel liner inside.

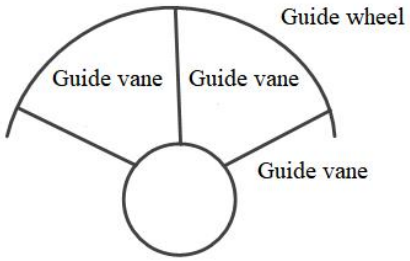

Figure 3.8.4.4 Energy-saving Appendage in Front of the Propeller

3.8.4.5 The joint weld of the energy-saving appendage in front of the propeller and the hull is to be ground smooth and the toes are to have a smooth transition.
3.8.4.6 100% external and at least 80% internal NDT is to be performed in the joint weld of surface shell of the energy-saving appendage in front of the propeller (including the external supporting structure) and the hull.

Appendix 1 GUIDELINES FOR CALCULATION OF BENDING MOMENT AND SHEAR FORCE DISTRIBUTION

1 General

1.1 Application

1.1.1 The evaluation of bending moments, shear forces and support forces for the system rudder– rudder stock may be carried out for some basic rudder types as outlined in 2.1 to 2.5 of this Appendix.

2 The Forces on Rudder–Rudder Stock

2.1 Spade rudder

Data for the analysis

l_{10} – l_{30} = lengths of the individual girders of the system, in m;

I_{10} – I_{30} = moments of inertia of these girders, in cm^4.

Load of rudder body P_R:

$$P_R = C_R / (l_{10} 10^3) \qquad \text{kN/m}$$

Moments and forces

The moments and forces may be determined by the following formulae:

$$M_b = C_R (l_{20} + (l_{10}(2c_1 + c_2) / 3(c_1 + c_2))) \qquad \text{N·m}$$

$$B_3 = \frac{M_b}{l_{30}} \qquad \text{N}$$

$$B_2 = C_R + B_3 \qquad \text{N}$$

where: C_R — rudder force, in N.

The maximum moment, M_c, in top of the cone coupling as shown in Figure 2.1 is applicable for the connection between the rudder and the rudder stock.

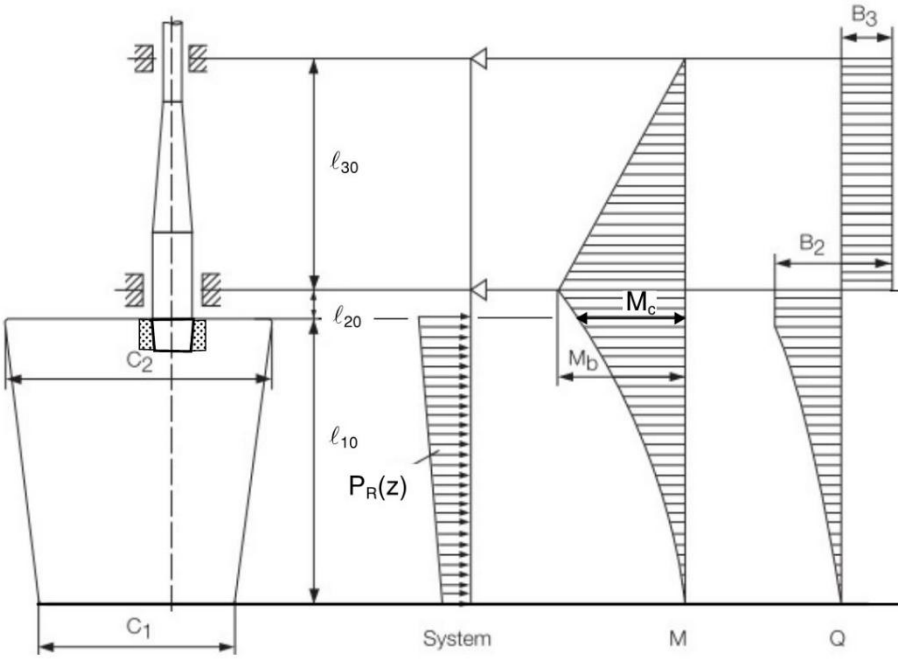

Figure 2.1 Spade rudder

2.2 Spade rudder with trunk

Data for the analysis

l_{10} – l_{30} = lengths of the individual girders of the system, in m;

I_{10} – I_{30} = moments of inertia of these girders, in cm^4.

Load of rudder body P_R:

$$P_R = C_R / ((l_{10} + l_{20})10^3) \qquad \text{kN/m}$$

Moments and forces

For a spade rudder with trunk extending inside the rudder, the strength is to be checked against the following two cases, and the moments and forces for the two cases defined above may be determined according to Figure 2.2(1) and 2.2(2), respectively.

(1) pressure applied on the entire rudder area;

Full rudder force $C_R = C_{R1} + C_{R2}$

total rudder torque $Q_R = Q_{R1} + Q_{R2}$

rudders stock bending moment $M_b = M_{CR2} - M_{CR1}$

(2) pressure applied only on rudder area below the middle of neck bearing.

Rudder force C_{R2} corresponding to rudder torque Q_{R2} acting at rudder blade area A_2 with rudders stock bending moment $M_b = M_{CR2}$

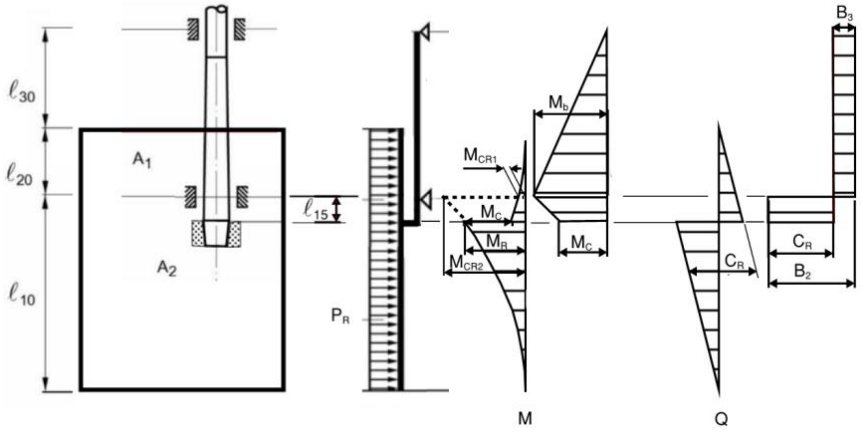

Figure 2.2(1)

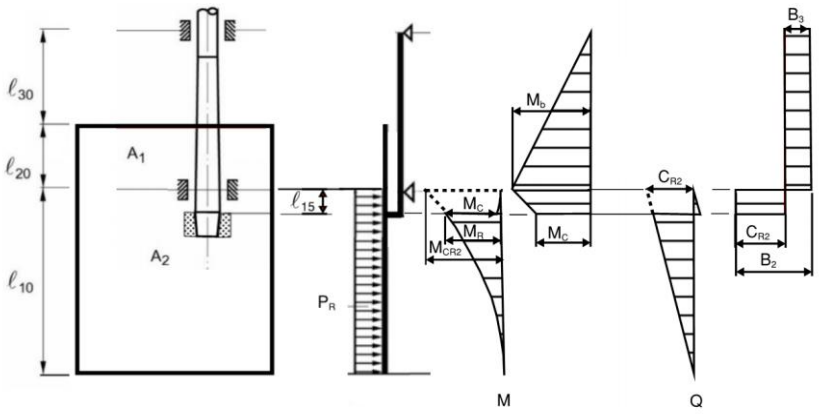

Figure 2.2(2)

$$M_{CR1} = C_{R1}(CG_{1Z} - l_{10}) \qquad \text{N·m}$$

$$M_{CR2} = C_{R2}(l_{10} - CG_{2Z}) \qquad \text{N·m}$$

where: C_{R1}: rudder force over the rudder blade area A_1;

C_{R2}: rudder force over the rudder blade area A_2;

CG_{1Z}: vertical position of the centre of gravity of the rudder blade area A_1;

CG_{2Z}: vertical position of the centre of gravity of the rudder blade area A_2;

$$C_R = C_{R1} + C_{R2} \qquad \text{N}$$

$$B_3 = (M_{CR2} - M_{CR1}) / (l_{20} + l_{30}) \quad \text{N}$$

$$B_2 = C_R + B_3 \quad \text{N}$$

2.3 Rudder supported by sole piece

Data for the analysis

l_{10} – l_{50} = lengths of the individual girders of the system, in m;

$I_{10} – I_{50}$ = moments of inertia of these girders, in cm^4.

For rudders supported by a sole piece the length l_{20} is the distance between lower edge of rudder body and centre of sole piece and I_{20} the moment of inertia of the pintle in the sole piece.

I_{50} = moment of inertia of sole piece around the z-axis, in cm^4;

l_{50} = effective length of sole piece, in m;

Load of rudder body P_R:

$$P_R = C_R / (l_{10} 10^3) \quad \text{kN/m}$$

Z — spring constant of support in the sole piece;

$$Z = 6.18 \times I_{50} / l_{50}^3 \quad \text{kN/m}$$

where: C_R – rudder force, in N.

Moments and forces

Moments and shear forces are indicated in Figure 2.3.

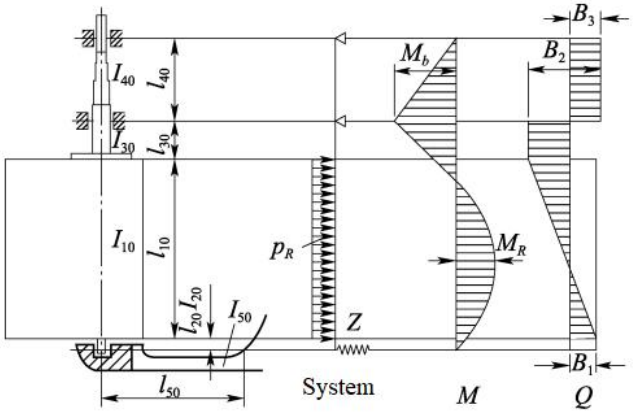

Figure 2.3 Rudder supported by sole piece

2.4 Semi spade rudder with one elastic support

Data for the analysis

l_{10} – l_{40} = lengths of the individual girders of the system, in m;

$I_{10} – I_{40}$ = moments of inertia of these girders, in cm^4.

Z — spring constant of support in the rudder horn:

$Z = 1/(f_b + f_t)$ kN/m, for the support in the rudder horn (see Figure 2.4.1);

f_b — unit displacement of rudder horn, in m, due to a unit force of 1 kN acting in the centre of support:

$$f_b = \frac{1.3 h^3}{6.18 I_n} \quad \text{m/kN (guidance value);}$$

I_n — moment of inertia of horizontal section of rudder horn around the x-axis, in cm^4 (see also Figure 2.4.1);

f_t — unit displacement due to torsion, in m/kN;

$$f_t = \frac{he^2 \sum u_i / t_i}{3.14 \times 10^8 F_T^2} \quad \text{m/kN}$$

F_T — mean of areas enclosed by outer and inner boundaries of the thin walled section of rudder horn (excluding the area of the inner hollow area), in m^2;

u_i — breadth in [mm] of the individual plates forming the F_T area;
t_i — thickness within the individual breadth u_i, in mm;
h — Height of the rudder horn, in m, defined in Figure 2.4.1. This value is measured downwards from the upper rudder horn end, at the point of curvature transition, to the mid-line of the lower rudder horn pintle;
e — distance as defined in Figure 2.4.2, in m, measured to $h/2$ of the height of the rudder horn;
Load of rudder body:

$$p_{R10}=\frac{C_{R2}}{l_{10}\times 10^3} \quad \text{kN/m}$$

$$p_{R20}=\frac{C_{R1}}{l_{20}\times 10^3} \quad \text{kN/m}$$

where: C_R, C_{R1}, C_{R2}, see 2.2 of this Appendix.
Moments and forces
Moments and shear forces are indicated in Figure 2.4.1.
Rudder horn
The loads on the rudder horn are as follows:
M_b — bending moment = $B_1 z$, in N·m;
M_{bmax}= $B_1 h$, in N·m;
Q — shear force = B_1, in N;
M_T(z) — torsional moment = $B_1 e(z)$, in N·m.
An estimate for B_1 is:
$B_1 = C_R b / (l_{20} + l_{30})$, in N.

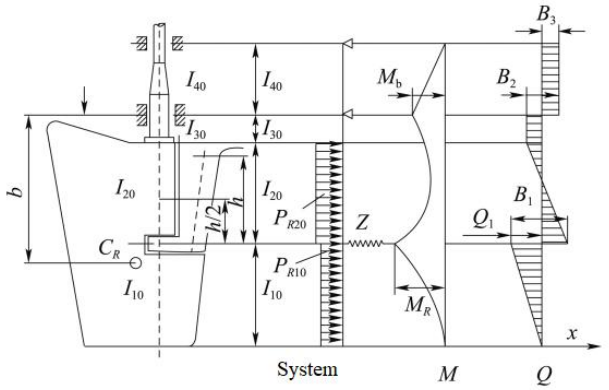

Figure 2.4.1 Semi spade rudder with one elastic support

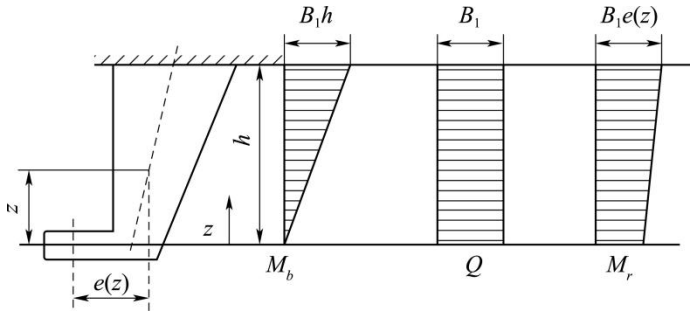

Figure 2.4.2 Rudder horn of semi spade rudder with one elastic support

2.5 Semi spade rudder with 2-conjugate elastic support

Data for the analysis
K_{11}, K_{12}, K_{22}: Rudder horn compliance constants calculated for rudder horn with 2-conjugate elastic supports (Figure 2.5.1).The 2-conjugate elastic supports are defined in terms of horizontal displacements, y_i, by the following equations:
at the lower rudder horn bearing:

$$y_1 = -K_{12}B_2 - K_{22}B_1$$

at the upper rudder horn bearing:

$$y_2 = -K_{11}B_2 - K_{12}B_1$$

where: y_1, y_2 — horizontal displacements, in m, at the lower and upper rudder horn bearings, respectively;

B_1, B_2 — horizontal support forces, in kN, at the lower and upper rudder horn bearings, respectively;

K_{11}, K_{12}, K_{22} — obtained, in m/kN, from the following formulae:

$$K_{11}=1.3\times\frac{\lambda^3}{3EJ_{1h}}+\frac{e^2\lambda}{GJ_{th}}$$

$$K_{12}=1.3\times\left[\frac{\lambda^3}{3EJ_{1h}}+\frac{\lambda^2(h-\lambda)}{2EJ_{1h}}\right]+\frac{e^2\lambda}{GJ_{th}}$$

$$K_{22}=1.3\times\left[\frac{\lambda^3}{3EJ_{1h}}+\frac{\lambda^2(d-\lambda)}{EJ_{1h}}+\frac{\lambda(h-\lambda)^2}{EJ_{1h}}+\frac{(h-\lambda)^3}{3EJ_{2h}}\right]+\frac{e^2\lambda}{GJ_{th}}$$

where: h — height of the rudder horn, in m, defined in Figure 2.5.1. This value is measured downwards from the upper rudder horn end, at the point of curvature transition, to the mid-line of the lower rudder horn pintle;

λ— length, in m, as defined in Figure 2.5.2. This length is measured downwards from the upper rudder horn end, at the point of curvature transition, to the mid-line of the upper rudder horn bearing. For $\lambda = 0$, the above formulae converge to those of spring constant Z for a rudder horn with 1-elastic support, and assuming a hollow cross section for this part;

e — rudder-horn torsion lever, in m, as defined in Figure 2.5.1 (value taken at $z = h/2$);

J_{1h} — moment of inertia of rudder horn about the x-axis, in m^4, for the region above the upper rudder horn bearing. Note that J_{1h} is an average value over the length λ (see Figure 2.5.1);

J_{2h} — moment of inertia of rudder horn about the x-axis, in m^4, for the region between the upper and lower rudder horn bearings. Note that J_{2h} is an average value over the length $h - \lambda$ (see Figure 2.5.1);

J_{th} — torsional stiffness factor of the rudder horn, in m^4. For any thin wall closed section:

$$J_{th}=\frac{4F_T^2}{\sum_i \frac{u_i}{t_i}} \quad m^4$$

F_T — mean of areas enclosed by outer and inner boundaries of the thin walled section of rudder horn (excluding the area of the inner hollow area), in m^2;

μ_i — length, in mm, of the individual plates forming the F_T area;

t_i — thickness, in mm, of the individual plates mentioned above.

Note that the J_{th} value is taken as an average value, valid over the rudder horn height.

Load of rudder body:

$$p_{R10}=\frac{C_{R2}}{l_{10}\times 10^3} \quad kN/m$$

$$p_{R20}=\frac{C_{R1}}{l_{20}\times 10^3} \quad kN/m$$

where: C_R, C_{R1}, C_{R2}, see 2.2 of this Appendix.

Moments and forces

Moments and shear forces are indicated in Figure 2.5.1.

Rudder horn bending moment

The bending moment acting on the generic section of the rudder horn is to be obtained, in N·m, from the following formulae:

between the lower and upper supports provided by the rudder horn:

$$M_H = F_{A1}z \quad N\cdot m$$

above the rudder horn upper-support:

$$M_H = F_{A1}z+F_{A2}(z-d_{lu}) \quad N\cdot m$$

where:

F_{A1} — support force at the rudder horn lower-support, in N, to be obtained according to Figure 2.5.1, and taken equal to B_1;

F_{A2} — support force at the rudder horn upper-support, in N, to be obtained according to Figure 2.5.1, and taken equal to B_2;

z — distance, in m, defined in Figure 2.5.2, to be taken less than the distance h, in m, defined in the same figure;

d_{lu} — distance, in m, between the rudder-horn lower and upper bearings (according to Figure 2.5.1, $d_{lu} = h - \lambda$).

Rudder horn shear force

The shear force Q_H acting on the generic section of the rudder horn is to be obtained, in N, from the following formulae:

between the lower and upper rudder horn bearings:

$$Q_H = F_{A1} \qquad \text{N}$$

above the rudder horn upper-bearing:

$$Q_H = F_{A1} + F_{A2} \qquad \text{N}$$

where: F_{A1}, F_{A2} — support forces, in N.

The torque acting on the generic section of the rudder horn is to be obtained, in N·m, from the following formulae:

between the lower and upper rudder horn bearings:

$$M_T = F_{A1} e(\text{z}) \qquad \text{N·m}$$

above the rudder horn upper-bearing:

$$M_T = F_{A1} e(\text{z}) + F_{A2} e(\text{z}) \qquad \text{N·m}$$

where: F_{A1}, F_{A2} — support forces, in N;

$e(z)$ — torsion lever, in m, defined in Figure 2.5.2.

Rudder horn shear stress calculation

For a generic section of the rudder horn, located between its lower and upper bearings, the following stresses are to be calculated:

τ_S — shear stress, in N/mm^2, to be obtained from the following formula:

$$\tau_s = \frac{F_{A1}}{A_H} \qquad \text{N/mm}^2$$

τ_T — torsional stress, in N/mm^2, to be obtained for hollow rudder horn from the following formula:

$$\tau_T = \frac{M_T 10^{-3}}{2F_T t_H} \qquad \text{N/mm}^2$$

For solid rudder horn, τ_T is to be calculated based on the specific geometrical shape.

For a generic section of the rudder horn, located in the region above its upper bearing, the following stresses are to be calculated:

τ_S — shear stress, in N/mm^2, to be obtained from the following formula:

$$\tau_s = \frac{F_{A1} + F_{A2}}{A_H} \qquad \text{N/mm}^2$$

τ_T — torsional stress, in N/mm^2, to be obtained for hollow rudder horn from the following formula:

$$\tau_T = \frac{M_T 10^{-3}}{2F_T t_H} \qquad \text{N/mm}^2$$

For solid rudder horn, τ_T is to be calculated based on the specific geometrical shape.

where:

F_{A1}, F_{A2} — support forces, in N;

A_H — effective shear sectional area of the rudder horn, in mm^2, in y-direction;

M_T — torque, in N·m;

F_T — mean of areas enclosed by outer and inner boundaries of the thin walled section of rudder horn (excluding the area of the inner hollow area), in m^2;

t_H — Plate thickness of rudder horn, in mm. For a given cross section of the rudder horn, the maximum value of τ_T is obtained at the minimum value of t_H.

Rudder horn bending stress calculation

For the generic section of the rudder horn within the length h, the following stresses are to be calculated:

σ_B — bending stress, in N/mm^2, to be obtained from the following formula:

$$\sigma_B = \frac{M_H}{W_X} \qquad \text{N/mm}^2$$

where: M_H — bending moment at the section considered, in N·m;

W_X — section modulus, in cm^3, around the *x*-axis (see Figure 2.5.2).

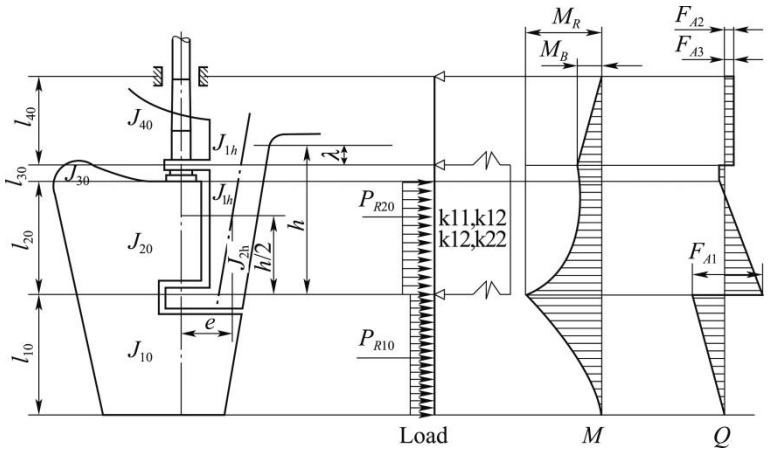

Figure 2.5.1

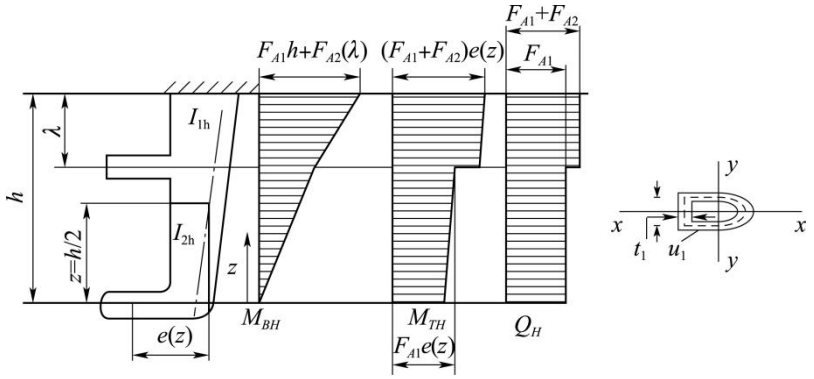

Figure 2.5.2

Appendix 2 DIRECT MOORING ANALYSES

1 General

1.1 As an alternative to the requirements for mooring lines in 3.2.4 of this Chapter, direct mooring analysis may be performed to determine the necessary mooring restraint, i.e. number and strength of mooring lines.

Direct analyses allow to optimize mooring equipment and arrangement for the individual ship and the port mooring facilities typical for the considered ship type and size.

2 Documentation

2.1 The calculations should be documented in a report. The report should include all assumptions made in calculations for the finally chosen mooring equipment, including lines, and its arrangement, reflected in the mooring arrangement plan.

3 Analysis methodology

3.1 Three dimensional quasi-static calculations should be performed to determine the acting mooring line forces. As a minimum, loads from wind and current should be accounted for in the analysis. Geometrical and material nonlinearities of mooring lines and fenders or breasting dolphins should be considered. An iterative calculation procedure should be applied to arrive at a converged solution with forces acting on mooring lines and on fenders or breasting dolphins being in equilibrium with forces and moments applied to the ship.

4 Environmental conditions

4.1 Mooring line forces should be calculated for environmental conditions given in 3.2.4.3 of this Chapter. Additional loads, e.g. wave loads or cross currents, or increased wind and current loads may be considered for certain ship types or for specific ports intended to be regularly called.

5 Steps to be taken in a direct mooring analysis

Direct assessment of mooring forces and determination of the necessary number and strength of mooring lines comprise the following steps:

(1) Determine port mooring facilities representative for the considered ship type and size

(2) Determine shipboard mooring equipment and arrangement

(3) Determine mooring line type(s) to be used

(4) Determine mooring layout(s) to be assessed

(5) Determine ship loading condition(s) to be assessed

(6) Select or determine wind and current drag coefficients

(7) Determine wind and current forces and moments

(8) Compute forces acting on all mooring line

(9) Determine necessary strength of mooring lines

(10) If strength of mooring lines should be altered, modify steps (2), (3) and/or (4) with or without changing the number of mooring lines and repeat steps (8) and (9)

5.1 Port mooring facilities

5.1.1 Characteristics of port mooring facilities have strong influence on the resulting mooring line forces. Mooring analysis should be performed for port mooring facilities representative for the considered ship type and size, i.e. type of berth, type and arrangement of hooks/bollards, type and arrangement of fenders or breasting dolphins and height of pier above waterline.

5.1.2 Fenders or breasting dolphins in many cases may not affect the critical mooring line loads. Hence, initially, generic fender or dolphin arrangements and infinitely stiff load deformation characteristics may be considered. If no fender or dolphin loads occur for load cases yielding the critical mooring line loads, more specific fender or dolphin arrangements and characteristics may be omitted.

5.1.3 If there are substantially different port mooring facilities typically encountered by the considered ship type, additional calculations should be performed to consider these variations.

5.2 Shipboard mooring equipment and arrangement

5.2.1 The mooring equipment and arrangement need to be chosen for the mooring analysis, i.e. location of mooring decks and location of mooring winches and fairleads. As a starting point, mooring equipment for the number of lines as determined by 3.2.4 of this Chapter may be chosen.

5.3 Mooring lines

5.3.1 The mooring analysis should apply the mooring line type(s) intended to be supplied with the vessel. The geometrical and material nonlinearities of the mooring lines should be considered by the mooring analysis. Load-deflection characteristics of mooring lines can be taken from data sheets of rope manufacturers. If given, characteristics of the broken-in ropes should be applied.

5.3.2 To achieve a good distribution of mooring line forces, mooring line type and characteristics should be at least same for lines in the same service, e.g. for head and stern lines, breast lines and spring lines. For very stiff mooring lines, e.g. made of steel or high modulus synthetic fibers, the use of elastic tails should be considered to enhance the elasticity in the mooring system and taken into account for the mooring analysis.

5.4 Mooring layout

5.4.1 For the assessment of forces acting on mooring lines, a realistic mooring layout needs to be assumed, i.e. for each mooring line it needs to be determined from which bollard or winch, along which path, through which fairlead it is led and to which shoreside hook or bollard it is connected. Inboard parts of the mooring lines (between fairlead and shipboard fixation point) contribute to the elongation behavior of the line and should be included in the analysis.

5.4.2 The maximum number of lines connected to one shore mooring point needs to be limited to not load the shore side mooring points unrealistically high. For multipurpose piers the number of lines per shore bollard should be limited to three. For other types of berths, the number mooring lines per shore mooring point is also limited, e.g., by the available number of hooks. Reasonable assumptions should be made based on typical berth types encountered by the considered ship type.

5.4.3 Alternative mooring layouts should also be assessed, considering possible and reasonable options to moor the ship to the assumed port mooring facilities. Also, a different position of the ship relative to the shoreside mooring bollards/hooks should be assessed to find the critical mooring line loads for the normal operation of the ship. Exemptions may be given to e.g. tankers, LNG carriers or ferries if typically moored in the same position relative to the shoreside mooring facilities.

5.5 Loading conditions

5.5.1 Mooring line forces should be calculated for loading conditions given in 3.2.4.3 of this Chapter.

5.6 Wind and current drag coefficients

5.6.1 To calculate the wind and current forces and moments acting on the ship, wind and current drag coefficients are needed for the considered ship type, size and loading condition. Drag coefficients should be as specific as possible for the considered ship and loading conditions.

5.6.2 There are different sources for drag coefficients. Some Industry Guidelines provide drag coefficients for tankers and LNG carriers which can be applied. Due to the similarity of hull forms and superstructures, these coefficients may also be used for bulk carriers and ore carriers. For other ship types drag coefficients may be taken from the literature, if available, or can be determined by CFD calculations or model tests. CFD calculations are to be justified with suitable validation and sensitivity studies.

5.6.3 There are some effects that can influence the drag coefficients, i.e. blockage (limited under keel clearance, solid quay walls), ship draft and wind shielding by solid quays and buildings or cargo stored on quays (e.g. container stacks). Effects from blockage and ship draft can only be accounted for by appropriate coefficients. Drag coefficient should be chosen or determined for realistic water depth to draft ratios and for the considered ship draft(s). Some Industry Guidelines provide current drag coefficients for ballast and loaded draft conditions and for different water depth to draft ratios. Wind shielding effects are typically not considered by the wind drag coefficients. The effect of wind shielding of solid quays may be considered by an equivalent reduction of the lateral wind area of the ship. Shielding by buildings or cargo stored on quays should not be considered as their presence is imponderable.

5.7 Calculation of wind and current forces and moments

5.7.1 Wind and current forces and moments can be calculated for the given environmental conditions with the geometrical particulars of the considered ship and the selected drag coefficients. Usually, the forces in longitudinal and transversal directions as well as the moment about the vertical ship axis (yaw) are calculated.

5.7.2 Wind forces and moments should be calculated for all directions in intervals of preferably 15°, but not more than 30°. Current forces and moments should be calculated for selected directions as per 3.2.4.3 of this Chapter. For ships regularly moored to non-solid piers or jetties, cross current may need to be considered in addition.

5.8 Calculation of mooring line forces

5.8.1 For all considered scenarios and all combinations of applied environmental conditions, the maximum mooring line force should be determined for groups of lines in the same service.

5.8.2 In case of all lines are intended to be attached to winches, brake rendering can be considered to better distribute line loads among all lines in a group of lines in the same service. Then, the average mooring line force of a group of lines may be determined and taken as mooring line force used to determine the necessary strength of the mooring lines according to section 5.9.

5.9 Strength of mooring lines

5.9.1 The necessary strength of mooring lines, i.e., the Ship Design Minimum Breaking Load (MBL_{SD}), results from the calculated maximum mooring line force ($F_{L,\ max}$) divided by the Work Load Limit (*WLL*) factor of mooring lines. The *WLL* factor and the resulting MBLSD for different mooring line materials are shown in the below table.

***WLL* factor and MBL_{SD}** **Table 5.9.1**

Mooring line material	*WLL* factor	MBL_{SD}
Steel wire	0.55	$1.82\times F_{L,max}$
Synthetic fibers	0.5	$2.0\times F_{L,max}$

5.9.2 Preferably, all lines supplied to the ship should have the same characteristics and strength to avoid confusion of lines. However, for significantly different maximum calculated line loads, lines in different service may also have different strength and characteristics, e.g. for head and stern lines other than for spring lines.

Appendix 3 DIRECT FORCE CALCULATION FOR ANCHORING EQUIPMENT

1 General

1.1 As an alternative to the prescriptive approach described in 3.2.1.2 of this Chapter direct force calculation may be performed to determine the necessary anchoring equipment for monohull ships with length less than 90m.

2 Total force F_{EN}

2.1 The total force (static + dynamic) F_{EN} , in kN, induced by wind and current acting on monohull in anchoring condition as defined in A1.1 may be calculated as follows:

$$F_{EN} = 2(F_{SLPH} + F_{SH} + F_{SS})$$

where: F_{SLPH} ——Static force on wetted part of the hull due to current;

F_{SH} ——Static force on hull due to wind;

F_{SS} ——Static force on superstructures due to wind.

2.1.1 Calculation of F_{SLPH}

Static force on wetted part of the hull due to current F_{SLPH} , in kN, is defined according to the following formula:

$$F_{SLPH} = \frac{1}{2}\rho C_f S_m V_c^2 10^{-3}$$

where: ρ ——Water density, equal to 1025kg/m^3;

C_f ——Coefficient equal to:

$$C_f = (1+k)\frac{0.075}{(\log R_e - 2)^2}$$

where: R_e ——Reynolds number equal to:

$$R_e = \frac{(V_c L_{WL})}{1.054 \cdot 10^{-6}}$$

k ——Coefficient equal to:

$$k = 0.017 + 20\frac{C_{bWL}}{L_{WL}^2 T^{-0.5} B_{WL}^{-1.5}}$$

C_{bWL} ——block coefficient at waterline equal to:

$$C_{bWL} = \frac{\Delta}{1.025 L_{WL} B_{WL} T}$$

where: Δ ——Moulded displacement at waterline, in m^3;

S_m ——Total wetted surface of the part of the hull under draught, in m^2. The value of S_m is to be given by the Designer. When this value is not available, S_m may be taken equal to $6 \cdot \Delta^{2/3}$;

V_c ——Speed of the current, in m/s.

2.1.2 Calculation of F_{SH}

Static force on hull due to wind F_{SH} , in kN, is defined according to the following formula:

$$F_{SH} = \frac{1}{2}\rho(C_{hfr}S_{hfr} + 0.02S_{hlat})V_W^2 10^{-3}$$

where: ρ ——Air density, equal to 1.22kg/m^3;

V_W ——Speed of the wind, in m/s;

S_{hfr} ——Front surface of hull and bulwark if any, in m^2, projected on a vertical plane of the ship situated aft of the aft end of the ship and perpendicular to the longitudinal axis of the ship;

S_{hlat} ——Partial lateral surface of one single side of the hull and bulwark if any, in m^2, through the overall length of the ship, projected on a vertical plane parallel to the longitudinal axis of the ship and delimited according to Figure 2.1.2. In Figure 2.1.2, B is the breadth of the hull, in m.

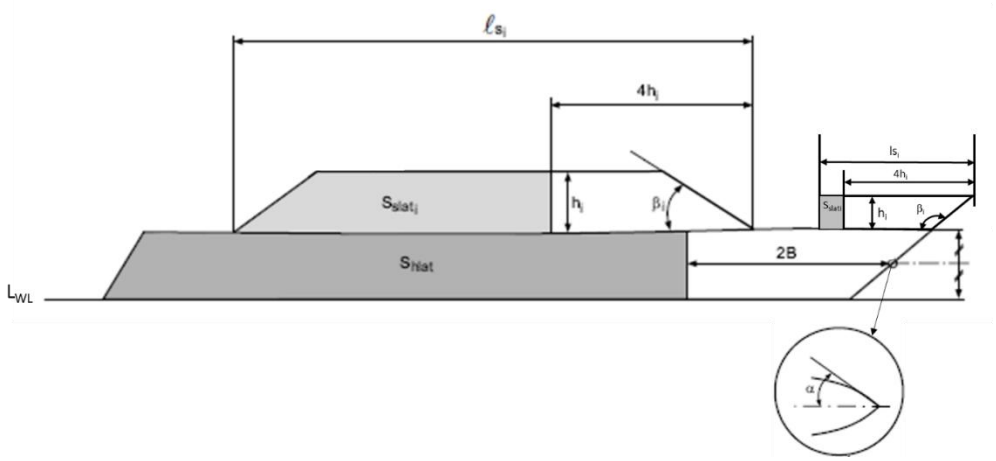

Figure 2.1.2

C_{hfr} ——Coefficient equal to $0.8\sin\alpha$, with α defined in Figure 2.1.2;

The upper part of the hull is the part extending from side to side to the uppermost continuous deck extending over the ship length.

2.1.3 Calculation of F_{SS}

(1) General case

Static force on superstructures and deckhouses due to wind F_{SS}, in kN, is defined according to the following formula:

$$F_{SS} = \frac{1}{2}\rho\sum(C_{sfr_i}S_{sfr_i} + 0.08S_{slat_i})V_W^2 10^{-3}$$

where: ρ ——Air density, equal to 1.22kg/m^3;

V_W ——Speed of the wind, in m/s;

S_{sfr_i} ——Front surface of tier i (superstructure or deckhouse, including bulwark if any), in m^2, projected on a vertical plane of the ship situated aft of the aft end of the ship and perpendicular to the longitudinal axis of the ship;

S_{slat_i} ——Partial lateral surface of one single side of tier i (superstructure or deckhouse, including bulwark if any), in m^2, projected on a vertical plane parallel to the longitudinal axis of the ship and delimited according to Figure 2.1.2. When $4h_i \geq l_{si}$, S_{slat_i} is to be taken equal to 0;

C_{sfr_i} ——Coefficient equal to $0.8\sin\beta_i$, with β_i defined in Figure 2.1.2 without being greater than 90°;

(2) Superstructures in the forward part of the ship

When superstructures are located in the front of the hull with front and side walls of superstructures in the continuity of the side shell, the static force induced by wind applied on these superstructures F_{SS}, in KN, is defined as the sum of the forces applied to each superstructure tier according to the following formula:

$$F_{SS} = \frac{1}{2}\rho\sum(C_{hfr_i}S_{hfr_i} + 0.08S_{slat_i})V_W^2 10^{-3}$$

where: S_{hfr_i} ——Front surface of tier i of the superstructure, in m^2, projected on a vertical plane of the ship situated aft of the aft end of the ship and perpendicular to the longitudinal axis of the ship

C_{hfr_i} ——Coefficient equal to $0.8\sin\alpha_s$, with α_s defined in Figure 2.1.2 and measured at mid height of the superstructure tier located in the front of the hull.

The static force is to be added to the static force calculated for the other superstructures and deckhouses according to 2.1.3(1) of this Appendix.

3 Anchor weight

3.1 The individual mass of anchor, in kg, is to be at least equal to:

for ordinary anchor: $P = (F_{EN}/7)\cdot 10^2$

for high holding power anchor: $P = (F_{EN}/10)\cdot 10^2$

for very high holding power: $P = (F_{EN}/15)\cdot 10^2$

4 Chain cable

4.1 Stud link chain cable scantling

Chain cable diameters are to be based on the minimum breaking load *BL* and proof load *PL* of steel grades.

Chain Cable Diameters **Table 4.1**

	CCS Grade 1	CCS Grade 2	CCS Grade 3
BL	$6F_{EN}$	$6.8F_{EN}$	$7.5F_{EN}$
PL	0.7*BL*		

The chain cable scantling is to be consistent with the mass of the associated anchor. In case the anchor on board is heavier by more than 7% from the mass calculated in 3.1 of this Appendix, the value of F_{EN} to take into account for the calculation of BL and PL is to be deduced from the actual mass of the anchor according to the formulae in 3.1 of this Appendix.

4.2 Length of individual chain cable

The length of chain cable L_{cc}, in m, linked to each anchor is to be at least equal to:

when P<180, $L_{cc} = 30\ln(\mathrm{P}) - 42$

when P≥180, L_{cc} to be selected according to Table 3.2.1.1(2) of this Chapter.

where: P: Anchor weight, in kg, defined in 3.1 of this Appendix for an ordinary anchor according to the considered case.

Chapter 4 STRENGTHENING FOR NAVIGATION IN ICE

Section 1 GENERAL PROVISIONS

4.1.1 General requirements

4.1.1.1 A ship classed with CCS intended to navigate in ice, for which any of the ice class notations as specified in 4.1.1.2 of this Section is desired and the corresponding requirements in Table 4.1.1.2 are complied with, may be assigned corresponding ice class notation. The requirements for ice class notations are in addition to those for the main class.

4.1.1.2 Ships, which comply with the requirements of Section 2 of this Chapter, may be assigned an appropriate ice class notation in accordance with 4.2.1.2, Section 2 of this Chapter; ships, which comply the requirements of Section 3 of this Chapter, may be assigned the notation of Ice Class B.

Table 4.1.1.2

Applicable ice navigation waters	Ice class	Requirements in corresponding chapters of the Rules	Additional requirements for ships having icebreaking capability
Polar sea	PC1 ~ PC7	Sections 1 ~ 2, Chapter 13 of PART EIGHT	–
	Icebreaker	Sections 1 ~ 2, Chapter 13 of PART EIGHT	–
	Icebreaker*	Rules for Heavy Icebreakers	–
Baltic or other sea areas with similar ice conditions in winter	B1*, B1 ~ B3	Section 2, Chapter 4 of PART TWO	Chapter 9 of PART EIGHT
Drift ice sea areas other than large stationary ice such as for coastal ice condition in northern part of China in winter	B	Section 3, Chapter 4 of PART TWO	–

4.1.1.3 An ice class notation may be requested by the Owner in accordance with 4.1.1.2 of this Section, subject to submission of service and operational conditions.

4.1.1.4 The equivalence between ice strengthening requirements for B1*, B1, B2, B3 and B of CCS and the ice classes of Finnish-Swedish Ice Class Rules (FSICR)① is given in Table 4.1.1.4.

Table 4.1.1.4

CCS	FSICR
B1*	IA Super
B1	IA
B2	IB
B3	IC
B	Between II and IC
Ships with the character of classification CSA	II

4.1.1.5 Ships intended to navigate in ice are to observe the local regulations concerning navigation in ice promulgated by the port authorities of respective countries, and attention is to be paid to the special requirements given by international industry organizations and oil companies.

4.1.1.6 In the design of structures, equipment and arrangements related to the safety and operation of the ship, the effect of low temperatures is to be taken into account.

Section 2 ICE STRENGTHENING FOR CLASSES B1*, B1, B2 AND B3

4.2.1 General requirements

4.2.1.1 The provisions of this Section apply to strengthening requirements for hull structures of merchant ships navigating in the Baltic or other sea areas with similar ice conditions in winter.

4.2.1.2 The ice class notations of ships and icebreaker-assisted ships are to be assigned as follows and the requirements for engine output are given in Chapter 14 of PART THREE of the Rules:

B1*– ships with such structure, engine output and other properties that they are normally capable of navigating in difficult ice conditions without the assistance of icebreakers;

① See TRAFICOM/281964/03.04.01.00/2023 for equivalence.

B1 – ships with such structure, engine output and other properties that they are capable of navigating in difficult ice conditions, with the assistance of icebreakers when necessary;
B2 – ships with such structure, engine output and other properties that they are capable of navigating in moderate ice conditions, with the assistance of icebreakers when necessary;
B3 – ships with such structure, engine output and other properties that they are capable of navigating in light ice conditions, with the assistance of icebreakers when necessary.
4.2.1.3 Restrictions on draughts when operating in ice are to be documented and kept on board readily available to the master. The maximum and minimum ice class draughts fore, amidships and aft are to be indicated in the class certificate, loading manual and shell plating expansion.
4.2.1.4 The sides of ship, to which the class notation of B1*, B1, B2 or B3 is assigned, are to be provided with a warning triangle and with an ice class draught mark at the maximum permissible ice class draught amidships (see Figure 4.2.1.4) when the upper ice waterline (UIWL) is lower than the fresh water load line in summer.

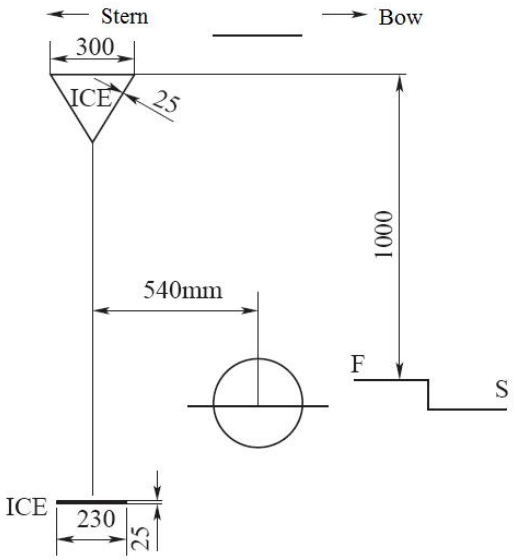

Figure 4.2.1.4 Warning Triangle and Maximum Ice Class Draught Mark (Starboard)

4.2.1.5 The upper edge of the warning triangle is to be located vertically above the "ICE" mark, 1000 mm higher than the summer fresh water load line, but in no case higher than the deck line. The sides of the triangle are to be 300 mm in length.
4.2.1.6 The ice class draught mark is to be located 540 mm abaft the centre of the load line ring or 540 mm abaft the vertical line of the timber load line mark, if applicable.
4.2.1.7 The marks and figures are to be cut out of 5 to 8 mm plate and then welded to the ship marks s. The marks and figures are to be painted in a red or yellow reflecting colour in order to make the marks and figures plainly visible even in ice conditions.
4.2.1.8 The dimensions of all marks and figures are to be the same as those used in the load line mark.

4.2.2 Ice class draught

4.2.2.1 Upper and lower ice waterlines
The upper ice waterline (UIWL) is to be the envelope of the highest points of the waterlines at which the ship is intended to operate in ice. The line may be a broken line.
The lower ice waterline (LIWL) is to be the envelope of the lowest points of the waterlines at which the ship is intended to operate in ice. The line may be a broken line.
4.2.2.2 Maximum and minimum draught fore and aft
The maximum and minimum ice class draughts at fore and aft perpendiculars are to be determined in accordance with the upper and lower ice waterlines.
The draught and trim, limited by the UIWL, must not be exceeded when the ship is navigating in ice. The salinity of the sea water along the intended route is to be taken into account when loading the ship.
The ship is always to be loaded down at least to the LIWL when navigating in ice. Any ballast tank, situated above the LIWL and needed to load down the ship to this water line, is to be equipped with devices to prevent the water from freezing. In determining the LIWL, regard is to be paid to the need for ensuring a reasonable degree of ice-going capability in ballast. The propeller is to be fully submerged, if possible entirely below the ice. The forward draught d_1 is not to be less than that obtained from the following formula:

$$d_1 = (2 + 0.00025\Delta)h_0 \quad \text{m, but need not exceed 4 } h_0,$$

where: Δ — displacement of the ship, in t, on the maximum ice-class draught according to 4.2.2.1 of this Section;

h_0 — level ice thickness, in m, see Table 4.2.4.2(1).

4.2.3 Engine output

The requirements for engine output related to hull structures are given in Chapter 14, PART THREE of the Rules.

4.2.4 Hull structural design

4.2.4.1 General

The method for determining the hull scantlings is based on certain assumptions concerning the nature of the ice load on the structure. These assumptions are from full scale observations made in the northern Baltic.

It has thus been observed that the local ice pressure on small areas can reach rather high values. This pressure may be well in excess of the normal uniaxial crushing strength of sea ice. The explanation is that the stress field in fact is multiaxial.

Further, it has been observed that the ice pressure on a frame can be higher than on the shell plating at midspacing between frames. The explanation for this is the different flexural stiffness of frames and shell plating. The load distribution is assumed to be as shown in Figure 4.2.4.1(1).

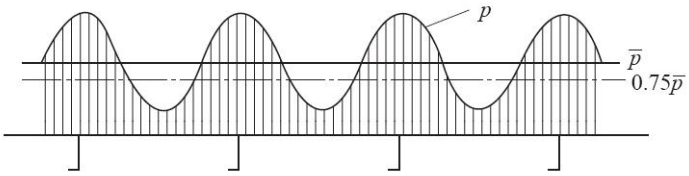

Figure 4.2.4.1(1) Ice Load Distribution on a Ship's Side

The formulae and values given in this Section may be substituted by direct analysis if they are deemed by the Administration or CCS to be invalid or inapplicable for a given structural arrangement or detail. Otherwise, direct analysis is not to be utilized as an alternative to the analytical procedures prescribed by explicit requirements in 4.2.4.3 to 4.2.4.5 of this Section.

Direct analyses are to be carried out using the load patch defined in 4.2.4.2 (p, h and l_a). The pressure to be used is $1.8p$ where p is determined according to 4.2.4.2(2). The load patch is to be applied at locations where the capacity of the structure under the combined effects of bending and shear are minimized. In particular, the structure is to be checked with load centred at the UIWL, $0.5h_0$ below the LIWL, and positioned several vertical locations in between. Several horizontal locations are also to be checked, especially the locations centred at the mid-span or –spacing. Further, if the load length l_a cannot be determined directly from the arrangement of the structure, several values of l_a are to be checked using corresponding values for c_a.

The acceptance criterion for designs is that the combined stresses from bending and shear, using the von Mises yield criterion, are lower than the yield point R_{eH}. When the direct calculation is using beam theory, the allowable shear stress is not to be larger than $0.9\tau_y$, where $\tau_y = R_{eH} / \sqrt{3}$.

If scantlings derived from these provisions are less than those required by other chapters of the Rules for a not ice strengthened ship, the latter is to be used.

Note 1: The frame spacings and spans defined in the following text are normally (in accordance with the appropriate rules for the ship in question) assumed to be measured along the plate and perpendicular to the axis of the stiffener for plates, along the flange for members with a flange, and along the free edge for flat bar stiffeners. For curved members the span (or spacing) is defined as the chord length between span (or spacing) points. The span points are defined by the intersection between the flange or upper edge of the member and the supporting structural element (stringer, web frame, deck or bulkhead). Figure 4.2.4.1(2) illustrates the determination of span and spacing for curved members.

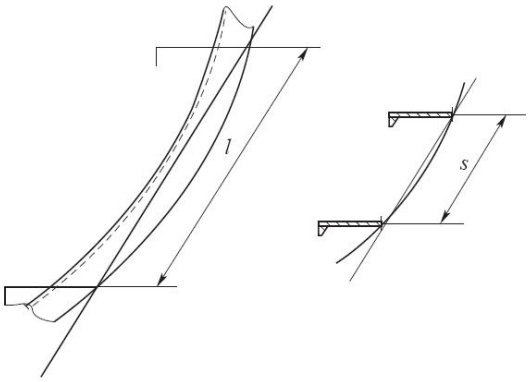

Figure 4.2.4.1(2) Definition of the Frame Span (left) and Frame Spacing (right) for Curved Members

Note 2: The effective breadth of the attached plate to be used for calculating the combined section modulus of the stiffener, stringer and web frame and attached plate is to be taken as the appropriate provisions in Section 2, Chapter 1 of this PART require. The effective breadth is in no case to be more than what is stated in the appropriate provisions above for the ship in question.

Note 3: The requirements for the section modulus and shear area of the frames, stringers and web frames in 4.2.4.4 to 4.2.4.6 are with respect to the effective member cross section. For such cases where the member is not normal to the plating, the section properties are to be calculated in accordance with the appropriate provisions in Section 2, Chapter 1 of this PART for the ship in question.

(1) Hull regions

For the purpose of this Section, the ship's hull is divided into regions as follows (see Figure 4.2.4.1(3)):

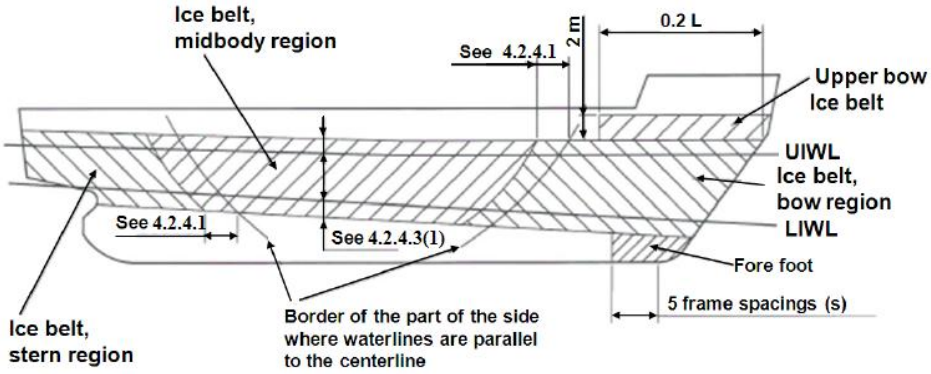

Figure 4.2.4.1(3) Ice Strengthened Regions of the Hull

Bow region: From the stem to a line parallel to and 0.04*L* aft of the forward borderline of the part of the hull where the waterlines run parallel to the centerline. For ice classes B1* and B1 the overlap over the borderline need not exceed 6 m, for ice classes B2 and B3 this overlap need not exceed 5 m.

Midbody region: From the aft boundary of the Bow region to a line parallel to and 0.04*L* aft of the aft borderline of the part of the hull where the waterlines run parallel to the centerline. For ice classes B1* and B1 the overlap over the borderline need not exceed 6 m, for ice classes B2 and B3 this overlap need not exceed 5 m.

Stern region: From the aft boundary of the Midbody region to the stern.

L is rule length of ship, see 1.1.2.1, Chapter 1 of this PART.

4.2.4.2 Ice load

(1) Height of the ice load area — an ice-strengthened ship is assumed to operate in open sea conditions corresponding to a level ice thickness not exceeding h_0 for the ice class in question. The design ice load height h (i.e. ice load height used in design calculation) of the area actually under ice pressure at any particular point of time is, however, assumed to be only a fraction of the ice thickness. The values for h_0 and h are given in Table 4.2.4.2(1).

Design Ice Thickness *h* and Level Ice Thickness h_0 **Table 4.2.4.2(1)**

Ice class	B1*	B1	B2	B3
Design ice thickness *h* (m)	0.35	0.30	0.25	0.22
level ice thickness h_0 (m)	1.0	0.8	0.6	0.4

(2) Ice pressure

The design ice pressure p is not to be less than that obtained from the following formula:

$$p = c_d c_p c_a p_0 \quad \text{MPa}$$

where: c_d — factor which takes account of the influence of the size and engine output of the ship. This factor is taken as maximum $c_d = 1$, to be calculated by the formula:

$$c_d = \frac{ak + b}{1000}$$

where: $k = \frac{\sqrt{\Delta P}}{1000}$;

a, b — see Table 4.2.4.2(2);

Δ — see 4.2.2.2 of this Section;

P —actual continuous engine output of the ship when sailing in ice in accordance with Chapter 14, PART THREE of the Rules, in kW; If additional power sources are available for propulsion power (e.g. shaft motors) in addition to the power of the main engine(s), they are also to be included in the total engine output used as the basis for hull scantling calculations. The engine output used for the calculation of the hull scantlings is to be clearly stated on the shell expansion drawing.

Table 4.2.4.2(2)

	Region			
	Bow		Midbody & Stern	
	$k \le 12$	$k > 12$	$k \le 12$	$k > 12$
a	30	6	8	2
b	230	518	214	286

c_p — factor that reflects the magnitude of the load expected in the hull area in question relative to the bow area, see Table 4.2.4.2(3);

Table 4.2.4.2(3)

Ice class	Region		
	Bow	Midbody	Stern
B1*	1.0	1.0	0.75
B1	1.0	0.85	0.65
B2	1.0	0.70	0.45
B3	1.0	0.50	0.25

c_a — factor which takes account of the probability that the full length of the area under consideration will be under pressure at the same time. It is calculated by the formula:

$c_a = \sqrt{\frac{l_0}{l_a}}$, maximum 1.0, minimum 0.35, l_0 = 0.6 m

where: l_a — see Table 4.2.4.2(4);

Selection of l_a **Table 4.2.4.2(4)**

Structure	Type of framing	l_a (m)
Shell	Transverse	Frame spacing
	Longitudinal	1.7 times frame spacing
Frames	Transverse	Frame spacing
	Longitudinal	Span of longitudinal
Ice stringer		Span of side stringer
Web frame		2 times web frame spacing

P_0 — nominal ice pressure; the value 5.6 MPa is to be used.

4.2.4.3 Shell plating

(1) Vertical extension of ice strengthening for plating (ice belt)

The vertical extension of the ice belt is to comply with Table 4.2.4.3.

Table 4.2.4.3

Ice class	Hull region	Above UIWL	Below LIWL
B1*	Bow	0.60 m	1.20 m

	Midbody		
	Stern		1.00 m
B1	Bow	0.50 m	0.90 m
	Midbody		0.75 m
	Stern		
B2 and B3	Bow	0.40 m	0.70 m
	Midbody		0.60 m
	Stern		

In addition, the following areas are to be strengthened:

Fore foot: For ice class B1*, the shell plating below the ice belt from the stem to a position five main frame spaces abaft the point where the bow profile departs from the keel line is to have at least the thickness required in the ice belt in the midbody region.

Upper bow ice belt: For ice classes B1* and B1 on ships with an open water service speed equal to or exceeding 18 knots, the shell plate from the upper limit of the ice belt to 2 m above it and from the stem to a position at least 0.2 *L* abaft the forward perpendicular, is to have at least the thickness required in the ice belt in the midbody region.

A similar strengthening of the bow region is advisable also for a ship with a lower service speed, when it is, e.g. on the basis of the model tests, evident that the ship will have a high bow wave.

Sidescuttles are not to be situated in the ice belt. If the weather deck in any part of the ship is situated below the upper limit of the ice belt (e.g. in way of the well of a raised quarter decker), the bulwark is to be given at least the same strength as is required for the shell in the ice belt. The strength of the construction of the freeing ports is to meet the same requirements.

(2) Plate thickness in the ice belt

For transverse framing the thickness *t* of the shell plating is not to be less than that obtained from the following formula:

$$t = 667s\sqrt{\frac{f_1 p_{PL}}{R_{eH}}} + t_c \qquad \text{mm}$$

For longitudinal framing the thickness *t* of the shell plating is not to be less than that obtained from the following formula:

$$t = 667s\sqrt{\frac{p}{f_2 R_{eH}}} + t_c \qquad \text{mm}$$

where: p_{PL}= 0.75*p*, *p*—see 4.2.4.2(2) of this Section;

f_1 = $1.3-\left(\frac{h}{s}+1.8\right)^2$, maximum 1.0, where *h* is design ice thickness as given in Table 4.2.4.2(1);

f_2 = $0.6+\frac{0.4s}{h}$, when $\frac{h}{s}\le 1$;

f_2 = $1.4-\frac{0.4h}{s}$, when $1\le\frac{h}{s}\le 1.8$;

s — frame spacing, in m;

t_c— increment for abrasion and corrosion, in mm; normally t_c is to be 2 mm; if a special surface coating, by experience shown capable to withstand the abrasion of ice, is applied and maintained, lower values may be approved.

R_{eH} — yield stress of the material, in N/mm^2. R_{eH} = 235 N/mm^2 for mild steel; R_{eH} = 315 N/mm^2 or higher for higher tensile steel. If steels with different yield stress are used, the actual values may be substituted for the above ones if accepted by CCS.

4.2.4.4 Side framing

(1) Vertical extension of the ice strengthening of the side framing

The vertical extension of the ice strengthening of the side framing is to at least comply with Table 4.2.4.4(1).

Table 4.2.4.4(1)

Ice class	Hull region	Above UIWL	Below LIWL
B1*	Bow	1.2 m	Down to double bottom or below top of the floors
	Midbody		2.0 m
	Stern		1.6 m
B1, B2 and B3	Bow	1.0 m	1.6 m
	Midbody		1.3 m

	Stern		1.0 m

Where an upper bow ice belt is required (see 4.2.4.3(1)), the ice-strengthened part of the framing is to be extended at least to the top of this ice belt.
Where the ice-strengthening would go beyond a deck or the top or bottom plating of a tank or tank top by no more than 250 mm, it can be terminated at that deck or top or bottom plating of the tank or tank top.
(2) Transverse frames
(a) Section modulus and shear area
The section modulus W of a main or intermediate transverse frame is not to be less than that obtained from the following formula:

$$W = \frac{pshl}{m_t R_{eH}} \times 10^6 \qquad \text{cm}^3$$

and the effective shear area A is not to be less than that obtained from the following formula:

$$A = \frac{\sqrt{3} f_3 phs}{2R_{eH}} \times 10^4 \qquad \text{cm}^2$$

where: p — see 4.2.4.2(2);
h — see Table 4.2.4.2(1);
s — frame spacing, in m;
l — span of the frame, in m;
m_t = $7\, m_0/(7\text{-}5h/l)$, where m_0 takes the boundary conditions into account. The values are given in Table 4.2.4.4(2);
f_3 — factor which takes into account the maximum shear force versus the load location and the shear stress distribution, $f_3 = 1.2$;
R_{eH} — yield stress of the material, in N/mm^2.

Value m_0 **Table 4.2.4.4(2)**

Boundary condition	m_0	Example
	7	Frames in a bulk carrier with top wing tanks
	6	Frames extending from the tank top to a single deck
	5.7	Continuous frames between several decks or stringers
	5	Frames extending between two decks only

Note: The boundary conditions are those for the main and intermediate frames. Load is to be applied at mid span. Where less than 15% of the span, l, of the frame is situated within the ice-strengthening zone for frames, ordinary frame scantlings may be used.

(b) Requirements for upper end of transverse framing
The upper end of the strengthened part of a main frame and of an intermediate ice frame is to be attached to a deck, top or bottom plating of a tank or an ice stringer.
Where an intermediate frame terminates above a deck or a stringer which is situated at or above the upper limit of the ice belt, the part above the deck or stringer may have the scantlings required in this PART for an non ice-strengthened ship and the upper end of an intermediate frame may be connected to the adjacent frames by a horizontal member having the same scantlings as the main frame.

(c) Requirements for lower end of transverse framing

The lower end of the strengthened part of a main frame and of an intermediate ice frame is to be attached to a deck, top or bottom plating of a tank or an ice stringer.

Where an intermediate frame terminates below a deck, tank top (or tank bottom) or ice stringer which is situated at or below the lower limit of the ice belt, the lower end may be connected to the adjacent main frames by a horizontal member of the same scantlings as the main frames. Note that the main frames below the lower edge of ice belt must be ice strengthened, see 4.2.4.4(1).

(3) Longitudinal frames

The following requirements are intended for longitudinal frames with all end connection:

(a) Frames with brackets

The section modulus W of a longitudinal frame is not to be less than that obtained from the following formula:

$$W=\frac{f_4 phl^2}{mR_{eH}}\times 10^6 \quad \text{cm}^3$$

and effective shear area A of a longitudinal frame is not to be less than that obtained from the following formula:

$$A=\frac{\sqrt{3} f_4 f_5 phl}{2R_{eH}}\times 10^4 \quad \text{cm}^2$$

(In calculation of the actual shear area of the frames, the shear area of the brackets is not to be taken into account.)

where:

p — see 4.2.4.2(2);

l — total span of frame, in m;

m — boundary condition factor; m = 13.3 for a continuous beam with brackets; where the boundary conditions deviate significantly from those of a continuous beam, e.g. in an end field, a smaller boundary factor may be required.

s — spacing of longitudinals, in m;

f_4 — factor which takes account of the load distribution to adjacent frames, $f_4 = (1\text{-}0.2\frac{h}{s})$, where h is design ice thickness as given in Table 4.2.4.2(1);

f_5 — factor which takes into account the maximum shear force versus load location and the shear stress distribution, f_5 = 2.16;

R_{eH} — yield stress of the material, in N/mm^2.

(4) General requirements for side framing

(a) The attachment of frames to supporting structures: within the ice-strengthened area all frames are to be effectively attached to all the supporting structures. A longitudinal frame is to be attached by brackets to all the supporting web frames and bulkheads. When a transversal frame terminates at a stringer or deck, a bracket or similar construction is to be fitted. When a frame is running through the supporting structure, both sides of the web plate of the frame are to be connected to the structure (by direct welding, collar plate or lug). When a bracket is installed, it has to have at least the same thickness as the web plate of the frame and the edge has to be appropriately stiffened against buckling.

(b) Support of frames against instability, in particular tripping:

The frames are to be attached to the shell by double continuous weld. No scalloping is allowed (except when crossing shell plate butts).

The web thickness of the frames is to be at least the maximum of the following:

- $\frac{h_w\sqrt{R_{eH}}}{C}$, h_w is the web height and C = 805 for profiles and C = 282 for flat bars;
- half of the net thickness of the shell plating, $t - t_c$. For the purpose of calculating the minimum web thickness of frames, the required thickness of the shell plating is to be calculated according to 4.2.4.3 using the yield strength R_{eH} of the frames;
- 9 mm.

Where there is a deck, top or bottom plating of a tank, tank top or bulkhead in lieu of a frame, the plate thickness of this is to be calculated as above, to a depth corresponding to the height of the adjacent frames. In such a case, the material properties of the deck, top or bottom plating of the tank, tank top or bulkhead and the frame height h_w of the adjacent frames are to be used in the calculations, and the constant C is to be 805.

Asymmetrical frames and frames which are not at right angles to the shell (web less than 90 degrees to the shell) are to be supported against tripping by brackets, intercostals, stringers or similar at a distance not exceeding 1.3 m. For frames with spans greater than 4 m, the extent of anti-tripping supports is to be applied to all regions and for all ice classes. If the span is less than or equal to 4.0 m, the supports against tripping are required in the following regions:

B1*	All hull regions
B1	Bow and midbody regions
B2 and B3	Bow region.

Direct calculation methods may be applied to demonstrate the equivalent level of support provided by alternative arrangements.

4.2.4.5 Ice stringers

(1) Stringers within the ice belt

The section modulus W of a stringer situated within the ice belt is not to be less than that obtained from the following formula:

$$W = \frac{f_6 f_7 phl^2}{mR_{eH}} \times 10^6 \qquad \text{cm}^3$$

The effective shear area A is not to be less than that obtained from the following formula:

$$A = \frac{\sqrt{3} f_6 f_7 f_8 phl}{2R_{eH}} \times 10^4 \quad \text{cm}^2$$

where: p — see 4.2.4.2(2);

h — see Table 4.2.4.2(1), the product ph is not to be taken as less than 0.15;

m — see 4.2.4.4(3)(a) of this Section;

l — span of the stringer, in m;

f_6 — factor which takes account of the distribution of load to the transverse frames, to be taken as 0.9;

f_7 — safety factor of stringers, to be taken as 1.8;

f_8 — factor that takes into account the maximum shear force versus load location and the shear stress distribution, $f_8 = 1.2$;

R_{eH} — yield stress of the material, in N/mm^2.

(2) Stringers outside the ice belt

The section modulus W of a stringer situated outside the ice belt is not to be less than that obtained from the following formula:

$$W = \frac{f_9 f_{10} phl^2}{mR_{eH}} \left(1 - \frac{h_s}{l_s}\right) \times 10^6 \qquad \text{cm}^3$$

The effective shear area A is not to be less than that obtained from the following formula:

$$A = \frac{\sqrt{3} f_9 f_{10} f_{11} phl}{2R_{eH}} \left(1 - \frac{h_s}{l_s}\right) \times 10^4 \quad \text{cm}^2$$

where: p — see 4.2.4.2(2);

h — see Table 4.2.4.2(1), the product ph is not to be taken as less than 0.15;

m — see 4.2.4.4(3)(a) of this Section;

l — span of the stringer, in m;

h_s — the distance to the ice belt, in m;

l_s — the distance to the adjacent ice stringer, in m;

f_9 — factor which takes account of the distribution of load to the transverse frames, to be taken as 0.80;

f_{10} — safety factor of stringers, to be taken as 1.8;

f_{11} — factor that takes into account the maximum shear force versus load location and the shear stress distribution, $f_{11} = 1.2$;

R_{eH} — yield stress of the material, in N/mm^2.

(3) Deck strips

Deck strips abreast of hatches and serving as ice stringers are to comply with the section modulus and shear area requirements in 4.2.4.5(1) and 4.2.4.5(2) of this Section respectively. In the case of very long hatches CCS may permit the product ph to be taken as less than 0.15 but in no case as less than 0.10.

Regard is to be paid to the deflection of the ship's sides due to ice pressure in way of very long (hatch length more than $B/2$, where B is moulded breadth) hatch openings when designing weather deck hatch covers and their fittings.

4.2.4.6 Web frames

(1) Load

The ice load F transferred to a web frame from an ice stringer or from longitudinal framing is to be calculated by the following formula:

$$F = f_{12} phS \quad \text{MN}$$

where: p — see 4.2.4.2(2), in calculation of c_a however, l_a is to be taken as $2S$;

h — see Table 4.2.4.2(1), the product ph is not to be taken as less than 0.15;

S — distance between web frames, in m;

f_{12} — safety factor of web frames, to be taken as 1.8.

In case the supported stringer is outside the ice belt, the force F is to be multiplied by $1- h_s/l_s$, where h_s and l_s are to be taken as defined in 4.2.4.5(2).

(2) Section modulus and shear area

The effective shear area A is not to be less than that obtained from the following formula:

$$A = \frac{\sqrt{3} f_{13} \alpha Q}{R_{eH}} \times 10^4 \qquad \text{cm}^2$$

where: Q — maximum calculated shear force under the ice load F, as given in 4.2.4.6(1);

f_{13} — factor that takes into account the shear force distribution, $f_{13} = 1.1$;

α — see Table 4.2.4.6(2);

R_{eH} — yield stress of the material, in N/mm^2.

The section modulus W is not to be less than that obtained from the following formula:

$$W = \frac{M}{R_{eH}} \sqrt{\frac{1}{1-(\gamma A / A_a)^2}} \times 10^6 \quad \text{cm}^3$$

where: M — maximum calculated bending moment under the ice load F, this is to be taken as $M = 0.193Fl$, where F is given in 4.2.4.6(1) and l is span of web frames;

γ — see Table 4.2.4.6(2);

A — required shear area calculated in accordance with this paragraph, in cm^2;

A_a — actual cross sectional area of the web frame, $A_a = A_f + A_w$, where are given in Table 4.2.4.6(2)①;

R_{eH} — yield stress of the material, in N/mm^2.

Table 4.2.4.6(2)

$\frac{A_f}{A_w}$	0	0.20	0.40	0.60	0.80	1.00	1.20	1.40	1.60	1.80	2.00
α	1.50	1.23	1.16	1.11	1.09	1.07	1.06	1.05	1.05	1.04	1.04
γ	0	0.44	0.62	0.71	0.76	0.80	0.83	0.85	0.87	0.88	0.89

Notes: ① A_f is the actual cross section area of free flange and A_w is the actual effective cross section area of web plate.

② If the ratio of A_f/A_w is an intermediate value, a and γ may be obtained by interpolation.

4.2.4.7 Stem

The stem is to be made of rolled, cast or forged steel or of shaped steel plates as shown in Figure 4.2.4.7(1).

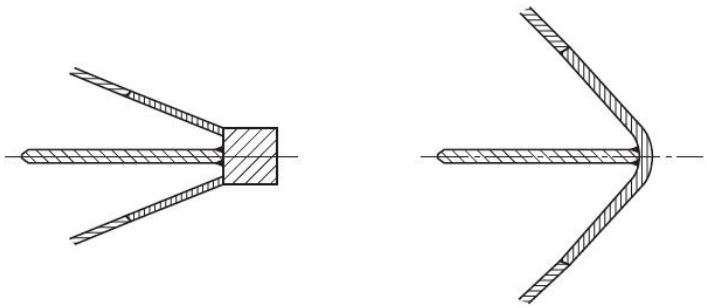

Figure 4.2.4.7(1) Examples of Suitable Stems

The plate thickness of a shaped plate stem and in the case of a blunt bow, any part of the shell where $\alpha \geq 30°$ and $\psi \geq 75°$ is not to be less than the value calculated according to 4.2.4.3 assuming that:

s — spacing of elements supporting the plate, in m;

p_{PL} = p, in MPa, see 4.2.4.3;

l_a — spacing of vertical supporting elements, in m;

α, ψ — see Figure 4.2.4.7(2), where α is the angle of the waterline at $B/4$ in bow region, in °; ψ is flare angle calculated as $\psi = \arctan\left(\frac{\tan\varphi}{\sin\alpha}\right)$ where φ is the rake of the bow at each location, in °; φ_1 is the rake of the stem at the centerline and φ_2 is the rake of the bow at $B/4$.

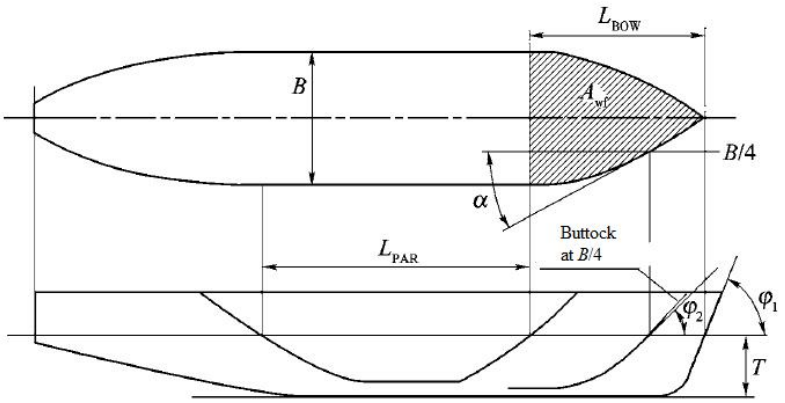

Figure 4.2.4.7(2)

The stem and the part of a blunt bow defined above are to be supported by floors or brackets spaced not more than 0.6 m apart and having a thickness of at least half the plate thickness. The reinforcement of the stem is to extend from the keel to a point 0.75 m above UIWL or, in case an upper bow ice belt is required (4.2.4.3(1)), to the upper limit of this.

4.2.4.8 Stern

The introduction of new propulsion arrangements with azimuthing thrusters, which provide improved manoeuvrability, will result in increased ice loading of the stern region and the stern area. This fact is to be considered in the design of the aft/stern structure.

In order to avoid very high loads on propeller blade tips, the minimum distance between propeller(s) and hull (including stern frame) is at least to satisfy the requirements of 2.14.4.1 of Section 14, Chapter 2 of this PART.

On twin and triple screw ships the ice strengthening of the shell and framing is to be extended to the tank top for 1.5 m forward and aft of the side propellers.

Shafting and stern tubes of side propellers are normally to be enclosed within plated bossings. If detached struts are used, due consideration is to be taken of their design, strength and attachments to the hull.

4.2.5 Rudders and steering arrangements

The scantlings of rudder post, rudder stock, pintles, steering engine as well as the capability of the steering engine are to satisfy the provisions of the relevant Chapters of the Rules. The maximum service speed of the ship to be used in the calculation is not to be less than that given in Table 4.2.5. If the actual maximum service speed of the ship is higher than that given in Table 4.2.5, the actual speed is to be used in the calculation.

Table 4.2.5

Ice Class	Speed (kn)	Ice Class	Speed (kn)
B1*	20	B2	16
B1	18	B3	14

The local scantlings of rudders are to be determined assuming that the whole rudder belongs to the ice belt. Further, the rudder plating and frames are to be designed using the ice pressure p for the plating and frames in the midbody region.

For ice classes B1* and B1, the rudder (rudder stock and the upper part of the rudder) are to be protected from direct contact with intact ice by an ice knife that extends below the LIWL, if practicable (or equivalent means). Special consideration is to be given to the design of the rudder and the ice knife for ships with flap-type rudders.

For ice classes B1* and B1, due regard is to be paid to the large loads that arise when the rudder is forced out of the midship position while going astern in ice or into ice ridges. Suitable arrangement such as rudder stoppers is to be installed to absorb these loads.

Relief valves for hydraulic pressure in rudder turning mechanism(s) are to be installed. The components of the steering gear (e.g. rudder stock, rudder coupling, rudder horn etc.) are to be dimensioned to withstand loads causing yield stresses in the rudder stock.

Section 3 ICE STRENGTHENING FOR CLASS B

4.3.1 Shell plating

4.3.1.1 The longitudinal extent of strengthening of the shell plating within the ice belt is to be from the stem to the greatest breadth of the ship at the full-load waterline but need not exceed 0.2*L*, and the vertical extent is to be from 500 mm above the draught on the fresh water load line in summer to 500 mm below the minimum draught fore. The strengthened area is to be indicated on the plan of shell expansion.

4.3.1.2 The changes in thickness of the shell plating within the ice belt are to be made gradually, and the thickness *t* is not to be less than the value obtained from the following formula:

$$t = 1.25t_0\sqrt{K}$$, but need not be greater than 25 mm

where: t_0— the Rule thickness of amidships shell plating according to Section 3, Chapter 2 of this PART (assumed as ordinary steel), in mm. In calculation, *s* is to be taken as the spacing of longitudinals/frames, (for the actual type of framing in bow region), but the intermediate longitudinals/frames not included;

K— material factor.

4.3.1.3 For ships of ice strengthening for class B, a warning triangle may be provided in accordance with the requirements of 4.2.1.4 as necessary.

4.3.2 Frames and longitudinals

4.3.2.1 If intermediate frames are fitted in the fore peak or within the region from the stem to 0.075*L* (where the latter has a larger scope than the former), the section modulus of the intermediate frames is to be not less than 75% of that of the region where they are fitted. The vertical extent of the intermediate frames is to be from 1,000 mm below the ballast waterline to 1,000 mm above the summer fresh water load line, and the frames need not be connected at their ends.

If intermediate frames are not fitted, the frame spacing is not to exceed 60% of the spacing of the amidships frames, but in no case is to be greater than 0.5 m.

4.3.2.2 For a distance along the line of extension of the stringers, panting beams or perforated platforms in the fore peak tank, starting from their respective connections with side shell and leading aft to the greatest breadth of the ship at the full-load waterline (but not necessarily over 0.2*L*), tripping brackets are to be fitted at each frame.

4.3.2.3 If longitudinal framing is fitted within the region from the stem to 0.075*L* (where the latter has a larger scope than the former) of the ship, the arrangement and scantling of longitudinals within the region are to comply with the following requirements:

(1) Continuous intermediate longitudinals are to be fitted within the region, and the vertical extent is to be the same as that of intermediate frames as specified in 4.3.2.1 of this Section.

(2) The distance between intermediate longitudinals and longitudinals within the region is not to be greater than 0.5 m.

(3) The section modulus of longitudinals and intermediate longitudinals within the region is to comply with applicable requirements of 2.7.5 of Section 7, Chapter 2 of this PART, but the spacing of longitudinals *s* is to be taken as 1.5 times the distance between intermediate longitudinals and adjacent longitudinals in calculation.

Where it is difficult to fit intermediate longitudinals and such longitudinals will be spaced not more than 700 mm apart, they may be dispensed with, provided that the plate thickness *t* within the region complies with the following formula:

$$t = 1.58t_0\sqrt{K}$$, but need not be greater than 25 mm

where: t_0 — the Rule thickness of amidships shell plating according to Section 3, Chapter 2 of this PART(assumed as ordinary steel), in mm. In calculation, *s* is to be taken as the spacing of longitudinals;

K— material factor.

4.3.2.4 Tripping brackets or similar supports against tripping are to be fitted in way of an inclined frame fitted to the ice shell plating in the fore peak or within the region from the stem to 0.075*L* (where the latter has a larger scope than the former) in accordance with 4.2.4.4(4)(b).

4.3.3 Stem

4.3.3.1 The plate thickness of a welded plate stem for 600 mm above the summer fresh water load line is to be 1.1 times the Rule thickness, but need not exceed 25 mm. The thickness of the remainder of the stem may be gradually tapered to that of the shell end at the upper deck.

CHAPTER 5 DOUBLE HULL OIL TANKERS

Section 1 GENERAL PROVISIONS

5.1.1 Application

5.1.1.1 This Chapter applies to the structures of cargo tanks and adjacent pump rooms, ballast tanks and cofferdams (excluding bulkheads not adjacent to cargo tanks) of double hull oil tankers having double bottoms and with machinery spaces being situated aft, intended to carry crude oil and petroleum products having a flash point not exceeding 60℃ (closed cup test) and a Reid vapour pressure which is below the atmospheric pressure. If not covered in this Chapter, the relevant requirements of Chapters 2 and 6 of this PART are to be complied with.

5.1.1.2 The double hull oil tankers intended to carry oils having a flash point exceeding 60℃ (closed cup test) only are also to comply with the requirements of this Chapter. Where the temperature of heated cargo oils is at least 10℃ below their flash point, the requirements of 5.1.4.4 to 5.1.4.8 and 5.4.1.3 of this Chapter may not be applicable. The scantlings and arrangements of tankers intended for cargoes other than the above oil will be specially considered in relation to the characteristics and density of the cargo. For oil tankers intended for the carriage of liquids with a density greater than 1.025 t/m^3, the structural strength of the cargo tank region is to be specially considered.

5.1.1.3 CSR oil tankers are to comply with the relevant requirements of PART NINE of the Rules.

5.1.2 Class notations

5.1.2.1 For oil tankers complying with the requirements of this Chapter, the notation of Oil Tanker, Double Hull, F.P. ≤ 60℃ or Oil Tanker, Double Hull, F.P. > 60℃ may be assigned.

5.1.2.2 For oil tankers complying with the requirements of PART NINE of the Rules, a notation of Oil Tanker, Double Hull, CSR is to be assigned.

5.1.3 Plans and documents

5.1.3.1 The following plans and documents are to be submitted for approval in addition to those required in Section 1 of Chapter 2 of this PART:

(1) Connections of longitudinals with other members;

(2) Details at intersections of transverse and longitudinal framing;

(3) Closing arrangements for all deck openings;

(4) Any dry cargo tanks or tanks for water ballast only, which are empty in the fully loaded condition, are to be indicated on the principal structural and arrangement plans;

(5) The location of all openings in the deck is to be indicated on the structural plan of deck.

5.1.4 Limitations of size and arrangement of cargo tanks

5.1.4.1 The wing cargo tank mentioned here refers to a cargo tank, with inner hull forming one of its boundaries, of an oil tanker with oil-tight longitudinal bulkheads. Other cargo tanks are referred to as centre tanks.

5.1.4.2 With regard to subdivision, size of cargo tanks, distance from side shell to inner hull and depth of double bottom, the requirements of Section 12, Chapter 1 of this PART are to be complied with. For oil tankers with *DW* less than 5,000 tons and the capacity of each cargo oil tank not exceeding 700 m^3, if arranged as double hull, the spacing *W* of double hull is not to be less than:

$$W = 0.4 + 2.4\,DW/20000 \quad \text{m}$$

The minimum value of $W = 0.76$ m

where: *DW* means the deadweight, in t.

5.1.4.3 Segregated ballast tanks, dedicated clean ballast tanks and slop tanks are to be arranged in compliance with the requirements of Section 12, Chapter 1 of this PART.

5.1.4.4 Cofferdams① are to be provided at the forward and aft ends of the cargo tanks region so as to separate oil tanks from engine rooms, boiler rooms, dry cargo holds and accommodation spaces. Cofferdams are to have an adequate spacing between their end bulkheads to permit easy access and cover the whole area of the end bulkheads of the cargo tank region. The spacing between the bulkheads is in general not to be less than 760 mm. For small oil tankers, where it is difficult to arrange cofferdams,

① The Suez Canal Authority requires that only pump rooms, or tanks which can be filled with water or liquids having a flash point greater than 66℃ (closed cup test) may be accepted as cofferdams.

smaller spacing may be accepted, but it is not to be less than 600 mm. Where a corner-to-corner situation occurs, protection may be formed by a diagonal plate across the corner. A pump room, water ballast tank or oil fuel tank may be accepted in lieu of a cofferdam.

5.1.4.5 Any access to spaces adjacent to a cargo tank is to be from the open deck. Passages or tunnels passing through or adjacent to a cargo tank and not separated from it by a cofferdam, are to be provided with mechanical ventilation, and any access is also to be from the open deck.

5.1.4.6 Where the lower portion of the pump room is recessed into the machinery space, the height of the recess is not, in general, to exceed 1/3 of the moulded depth above the baseline except that in the case of ships of not more than 25,000 metric tons deadweight, CCS may permit a recess in excess of such height, but not exceeding one half of the moulded depth of the ship.

5.1.4.7 The wheelhouse, where fitted above the cargo tank region, is to be separated from the cargo tank deck by means of an open space with a height of at least 2 m.

5.1.4.8 Means are to be provided to keep deck spills away from the accommodation and service areas. This may be accomplished by provision of a permanent continuous coaming of not less than 300 mm in height extending from side to side. Special consideration is to be given to the arrangements associated with stern loading and unloading for the prevention of deck spill from flowing over board.

5.1.5 Structural details

5.1.5.1 For oil tankers of over 65 m in length, the deck, bottom and inner bottom within the cargo tank region of tankers are to be longitudinally framed. Where the length of ship exceeds 190 m, the side shell, inner hull and longitudinal bulkheads are generally to be longitudinally framed. The hull structures beyond the cargo tank region may be framed either transversely or longitudinally. Constructional arrangements are to be made to ensure a gradual transition from the longitudinal framing to the transverse framing.

5.1.5.2 The typical midship section of double hull oil tankers and the structural members referred to in this Chapter are as shown in Figure 5.1.5.2.

5.1.5.3 Cargo tanks are enclosed by double bottom, wing ballast tank, empty cofferdams and deck. The loading of cargo and fuel oils is not permitted in the double bottoms and wing ballast tanks.

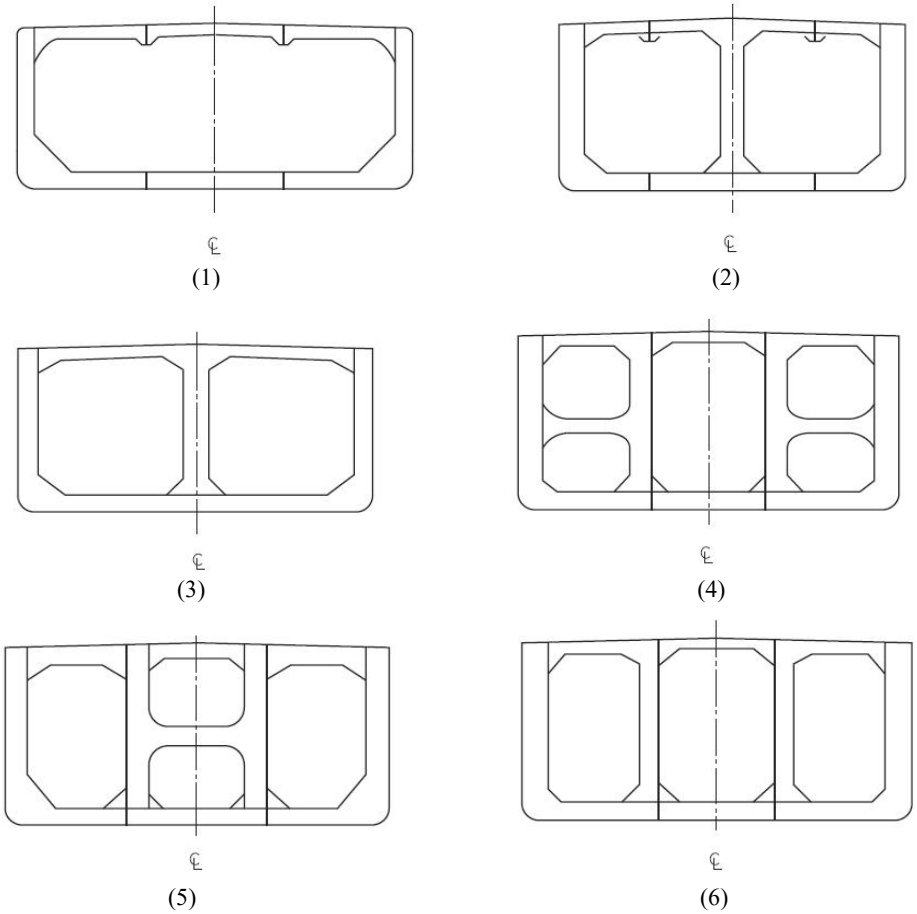

Figure 5.1.5.2(1) Typical Midship Section

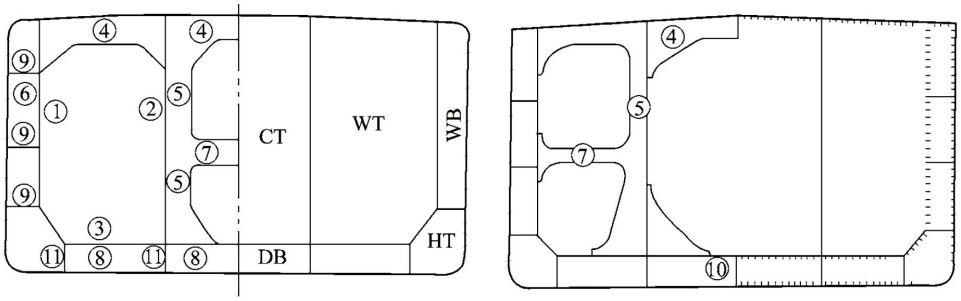
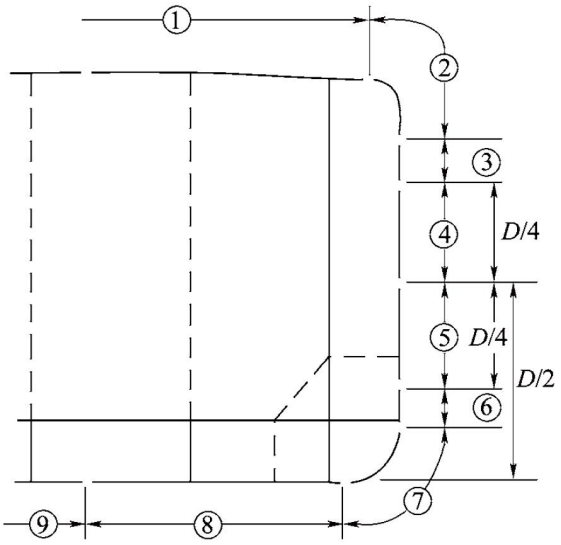


1— Inner hull; 2 — Longitudinal bulkhead; 3 — Inner bottom; 4 — Deck transverse; 5 — Vertical web on longitudinal bulkhead; 6 — Vertical web in wing ballast tank; 7 — Cross ties; 8 — Floor; 9 — Horizontal girder in wing ballast tank; 10 — Double bottom girder; 11 —Double bottom side girder; WB — Wing ballast tank; WT — Wing cargo tank; CT — Centre cargo tank; HT — Hopper tank; DB — Double bottom



1— Deck plating; 2 — Deck stringer and sheer strake; 3 — Side shell plating 1; 4 — Side shell plating 2; 5 — Side shell plating 3; 6 — Side shell plating 4; 7 — Bilge plating; 8 — Bottom shell plating; 9 — Plate keel

Figure 5.1.5.2(2) Typical Midship Section and Structural Members

5.1.6 Minimum thickness

5.1.6.1 Within the cargo tank region (including wing ballast tanks, empty cofferdams at the ends of the cargo tank region or between cargo tanks), the minimum thickness t of primary member webs and face plates, shell plating, deck plating, bulkhead plating and inner hull plating is not to be less than that obtained from the following formula:

$$t = 6.5 + L/50 \quad \text{mm, but not less than 7.5 mm}$$

where: L — length of ship, in m, taken not greater than 300 m.

The minimum thickness of secondary structural members are also to comply with the requirements mentioned above, but need not be greater than 11 mm.

5.1.6.2 The minimum thickness t of the members in pump rooms, cofferdams and other void spaces may be 1 mm less than that required in 5.1.6.1, but not less than 7.5 mm.

5.1.7 Longitudinal strength of double hull oil tankers

5.1.7.1 Double hull oil tankers are to comply with the longitudinal strength requirements specified in Section 2, Chapter 2 of this PART.

5.1.8 Direct calculations and fatigue assessment of hull structural strength

5.1.8.1 For oil tankers of 150 m or over in length, direct strength calculations are to be carried out for the primary members (longitudinal or transverse) in the cargo tank region according to the Appendix 1 of this Chapter.

5.1.8.2 For oil tankers of 150 m or over in length, the fatigue strength check is to be carried out for the following structural members in the cargo tank region in accordance with CCS Guidelines for Fatigue

Strength of Ship Structure:
(1) connections of longitudinals (bottom, side, deck and inner shell) to transverse web frames;
(2) connections of longitudinals (bottom, side, deck and inner shell) to transverse bulkheads;
(3) connections of hopper tanks or inner shell to inner bottoms.

Section 2 SHELL PLATING

5.2.1 General requirements

5.2.1.1 The formulae of this Section are applicable to the determination of thickness of longitudinally framed bottom shell plating, plate keels, bilge plating, side shell plating and shear strakes.

5.2.2 Bottom shell plating

5.2.2.1 The thickness t of bottom shell plating within 0.4L amidships is not to be less than that obtained from the following formulae:

$$t_1 = 0.052s(L_1 + 170)\sqrt{\frac{F_b}{K}} \text{ mm}$$

$$t_2 = 4.9s\sqrt{(h_w + 0.8d)K} \text{ mm}$$

where: s — spacing of longitudinals, in m, to be taken as not less than standard spacing of longitudinals;
d — draught, in m;
L_1 — length of ship, in m, to be taken as not more than 190 m;
F_b — reduction factor, see 2.2.5.6 of Section 2, Chapter 2 of this PART;
K — material factor;

$$h_w = 0.2B^{0.66} + \left(0.25 + \frac{0.82}{\sqrt{L}}\right)C$$

where: B — breadth of ship, in m;
L — length of ship, in m;
C — see 2.2.3.1 of Section 2, Chapter 2 of this PART.

5.2.3 Plate keels

5.2.3.1 The breadth b of the plate keel within the cargo tank region is not to be less than that obtained from the following formula:

$$b = 900 + 3.5L \quad \text{mm}$$

And the thickness t is not to be less than:

$$t = t_0 + 2.0 \quad \text{mm} \quad L \le 190 \text{ mm}$$
$$t = t_0 + 3.0 \quad \text{mm} \quad L > 190 \text{ mm}$$

where: L — length of ship, in m;
t_0 — the thickness of the bottom shell plating, in mm, as determined in 5.2.2.1 of this Section.

5.2.4 Bilge plating

5.2.4.1 The thickness t of bilge plating within 0.4L amidships is to be the same as that of bottom shell plating.

5.2.4.2 Where longitudinal bottom and side framing is adopted and no longitudinals are fitted at bilge, the thickness of bilge plating is not to be less than $\frac{rF_b}{165K}$ (r being the radius of the bilge, in mm, K being material factor, and F_b being reduction factor of bottom). The framing associated with such an arrangement is to comply with the requirements of 5.4.4.1 of Section 4 of this Chapter.

5.2.5 Side shell plating

5.2.5.1 Where longitudinal side framing is adopted, the thickness t of side shell plating within 0.4L amidships is to comply with the following requirements:

(1) The thickness t of side shell plating above $\frac{3}{4}D$ from the baseline is not to be less than that obtained from the following formulae:

$$t_1 = 0.058s(L + 110)\sqrt{\frac{F_d}{K}} \quad \text{mm}$$

$$t_2 = 7.1s\sqrt{h_w K} \quad \text{mm}$$

where: s — spacing of longitudinals, in m, not to be less than standard spacing of longitudinals;
L — length of ship, in m, to be taken as not greater than 190 m;
F_d — reduction factor, see 2.2.5.6 of Section 2, Chapter 2 of this PART;
K — material factor;
h_w — see 5.2.2.1 of this Section.

(2) The thickness t of side shell plating below $\frac{1}{4}D$ from the baseline is not to be less than that obtained from the following formulae:

$$t_1 = 0.06s(L+110)\sqrt{\frac{F_b}{K}} \quad \text{mm}$$

$$t_2 = 5.2s\sqrt{(h_w + 0.8d - 0.2D)K} \quad \text{mm}$$

where: s — spacing of longitudinals, in m, not to be less than standard spacing of longitudinals;
d — draught, in m;
F_b — reduction factor, see 2.2.5.6 of Section 2, Chapter 2 of this PART;
K — material factor;
L — length of ship, in m, to be taken not more than 190 m;
h_w — see 5.2.2.1 of this Section.

(3) The thickness t of side shell plating above $\frac{3}{4}D$ and below $\frac{1}{4}D$ from the baseline is not to be less than that obtained from the following formulae:

$$t_1 = \text{s}\,[t_{11} + (t_{12} - t_{11})h] \quad \text{mm}$$
$$t_2 = \text{s}\,[t_{21} + (t_{22} - t_{21})h] \quad \text{mm}$$

where: $t_{11} = \dfrac{t_{1,z=0.25D}}{s_{z=0.25D}}$

$t_{12} = \dfrac{t_{1,z=0.75D}}{s_{z=0.75D}}$

$t_{21} = \dfrac{t_{2,z=0.25D}}{s_{z=0.25D}}$

$t_{22} = \dfrac{t_{2,z=0.75D}}{s_{z=0.75D}}$

$h = \dfrac{z - 0.25D}{0.5D}$

$s_{z=0.25D}$ — spacing of longitudinals, in m, at $0.25D$, not to be less than the standard spacing of longitudinals;
$s_{z=0.75D}$ — spacing of longitudinals, in m, at $0.75D$, not to be less than the standard spacing of longitudinals;
$t_{1,z=0.25D}$ — thickness t_1 of plating, in mm, at $0.25D$;
$t_{1,z=0.75D}$ — thickness t_1 of plating, in mm, at $0.75D$;
$t_{2,z=0.25D}$ — thickness t_2 of plating, in mm, at $0.25D$;
$t_{2,z=0.75D}$ — thickness t_2 of plating, in mm, at $0.75D$;
s — spacing of longitudinals at the point under consideration, in m, not to be less than the standard spacing of longitudinals;
D — moulded depth, in m;
z — distance between the point under consideration and baseline.

(4) In calculation of t_1, except the minimum range of high tensile steel stipulated in Section 2 of Chapter 2, the material factor K may be taken as 1.

5.2.6 Sheer strakes

5.2.6.1 The breadth of the sheer strakes is to meet the requirements of 2.3.5.1 of Section 3, Chapter 2 of this PART.

5.2.6.2 The thickness t of sheer strakes within $0.4L$ amidships is not to be less than that obtained from the following formulae, also not to be less than that of the adjacent side shell plating:

$$t_1 = 0.06s(L_1 + 110)\sqrt{\frac{F_d}{K}} \quad \text{mm}$$

$$t_2 = 0.9s\sqrt{(L+75)K} \quad \text{mm}$$

where: s — spacing of longitudinals, in m, to be taken not less than standard spacing of longitudinals;
L — length of ship, in m;
L_1 = L, L being the length of ship, in m, to be taken not more than 190 m in calculation;
K — material factor;
F_d — reduction factor, see 2.2.5.6 of Section 2, Chapter 2 of this PART.

5.2.7 End shell plating

5.2.7.1 The thickness of shell plating at ends is to be in accordance with the relevant requirements of Section 3, Chapter 2 of this PART.

Section 3 DECKS

5.3.1 General requirements

5.3.1.1 The formulae of this Section are applicable to the determination of thickness of strength deck plating within 0.4L amidships.

5.3.2 Strength deck plating

5.3.2.1 The thickness t of strength deck plating within 0.4L amidships is not to be less than that obtained from the following formulae:

$$t_1 = 0.06s(L_1 + 110)\sqrt{\frac{F_d}{K}} \quad \text{mm}$$

$$t_2 = 0.9s\sqrt{(L+75)K} \quad \text{mm}$$

where: s — spacing of longitudinals, in m, to be taken not less than standard spacing of longitudinals;
L — length of ship, in m;
L_1 = L, L being the length of ship, in m, to be taken not more than 190 m in calculation;
K — material factor;
F_d — reduction factor, see 2.2.5.6 of Section 2, Chapter 2 of this PART.

5.3.2.2 The thickness of strength deck plating at ends is to comply with the relevant requirements of Section 4 of Chapter 2 of this PART.

5.3.3 Connections of deck stringers to sheer strakes

5.3.3.1 The connections of deck stringers to sheer strakes are to comply with the relevant requirements of Section 3 of Chapter 2 of this PART.

Section 4 DOUBLE BOTTOM STRUCTURE

5.4.1 General requirements

5.4.1.1 The scantlings and arrangement of the double bottoms in cargo tanks are to be as required in Section 6, Chapter 2 of this PART, except as otherwise specified in this Section.

5.4.1.2 The integrity of the double bottom is to be maintained. Manholes are not to be fitted on the inner bottom of cargo tanks and the access is not to be via the engine room. Access to double bottom tanks is to be provided by trunks from the exposed deck.

5.4.1.3 Arrangements are to be provided to enable double bottom tanks situated below cargo tanks to be filled with water ballast to eliminate flammable gases which possibly exist in these tanks.

5.4.1.4 Where a duct keel or pipe tunnel is fitted, the duct keel or pipe tunnel is not to be interconnected with the engine room. At least two accesses to open deck are to be provided at a maximum distance from each other. Where one of such accesses passes through a pump room, the access from the pump room to the duct keel or pipe tunnel is to be provided with a watertight cover.

5.4.1.5 Manholes are to be fitted in floors and side girders in compliance with the requirements in 2.6.1 of Section 6, Chapter 2 of this PART as well as those in Section 12, Chapter 1 of this PART.

5.4.1.6 Drain holes and vent holes are to be fitted in floors, side girders, bottom longitudinals and

inner-bottom longitudinals in compliance with the requirements in 2.6.1 of Section 6, Chapter 2 of this PART.

5.4.2 Bottom girders

5.4.2.1 The centre girders or duct keels are to be arranged at the longitudinal centerline of double bottoms. Side girders are also to be provided at sides.

5.4.2.2 Girders are to be provided below lower stools of the longitudinal or longitudinal corrugated bulkhead, whereas side girders are to be provided below hopper tank slope plating.

5.4.2.3 In way of vertically corrugated transverse bulkheads supported by stools, additional local girders are to be arranged in accordance with the requirements in 5.9.3.2 of Section 9 of this Chapter.

5.4.2.4 The thickness of centre keels is not to be less than that obtained from the following formula, and is also to comply with the requirements for deep tanks in Section 13, Chapter 2 of this PART:

$$t = (0.008\,h_0 + 1.0)\sqrt{K} \quad \text{mm}$$

where: h_0 — considered height of centre keels, in mm, see 2.6.2.1 of Section 6, Chapter 2 of this PART;

K — material factor.

5.4.2.5 The thickness of side plating of duck keels is not to be less than that obtained from the following formula, and is also to comply with the requirements for deep tanks in Section 13, Chapter 2 of this PART:

$$t = 0.008\,h_0\sqrt{K} \quad \text{mm}$$

where: h_0, K— the same as that in 5.4.2.4 of this Section.

5.4.2.6 The thickness of side girders is not to be less than that obtained from the following formula, and is to comply with the requirements for deep tanks in Section 13, Chapter 2 of this PART where side girders are watertight:

$$t = (0.007h_0 + 1.0)\sqrt{K} \quad \text{mm, but need not be greater than 14 mm}$$

where: h_0, K — the same as that in 5.4.2.4 of this Section.

5.4.2.7 For ships whose breadth is greater than 12 m, but not greater than 20 m, at least one side girder is to be provided at each side of the longitudinal centerline (including side girders in way of hopper tanks). For ships whose breadth is greater than 20 m, two side girders may be provided at each side of the longitudinal centerline (including side girders in way of hopper tanks and below longitudinal bulkheads). The number of side girders to be provided may also be determined by direct calculation.

5.4.2.8 Horizontal stiffeners are to be provided at centre girders, duck keels and side girders, of which the section moment of inertia is to comply with the requirements in 5.12.2.5 of this Chapter.

5.4.2.9 Brackets extending to adjacent longitudinals are to be provided at every other frame space at both sides of centre girders between solid floors. The thickness of brackets is to be the same as that of solid floors.

5.4.2.10 The inner framing of duct keels is to comply with the following requirements:

(1) Transverse bottom frames and inner bottom frames are to be provided in way of every other frame space in duct keels, and the section modulus W is not to be less than that obtained from the following formula:

$$W = 22sdl^2K \quad \text{cm}^3$$

where: s — spacing of frames, in m;

d — draft, in m;

l — span, in m, taken as spacing between both side plates of duct keels;

K — material factor.

(2) Both ends of transverse bottom frames and inner bottom frames are to be gradually enlarged and to be connected to side plating of duct keels, with the enlarged height being not be less than 1.5 times that of the frames. Brackets having a plate thickness equal to that of solid floors are to be provided at the corresponding position of outer side of the side plating and to be connected to the bottom and inner bottom longitudinals.

(3) Inner bottom longitudinals and bottom longitudinals are to be fitted within the duct keel on the centreline of the ship, which may be intercostal in way of transverse framing members.

5.4.2.11 For oil tankers of 90 m in length and upwards, the scantlings of centre keels, duct keels and side girders are to be checked by means of direct calculation, which is to comply with the requirements of Appendix 1 of this Chapter. Where the ship length is less than 150 m, other approved equivalent direct calculation methods may be used.

5.4.3 Bottom floors

5.4.3.1 Solid floors are to be provided below lower stools of transverse bulkheads and corrugated

transverse bulkheads.

5.4.3.2 The spacing of solid floors is, in general, to be not greater than $0.006L + 3.2$ in m, L being length of ship.

5.4.3.3 The thickness t of solid floors is not to be less than that obtained from the following formula:

$$t = (0.007h_0 + 1.0)\sqrt{K} \quad \text{mm, but need not be greater than 14 mm}$$

where: h_0, K — the same as that in 5.4.2.4 of this Section.

Watertight solid floors are also to comply with the requirements for deep tanks.

5.4.3.4 For oil tankers of 90 m in length and upwards, the thickness of floors is to be checked by means of direct calculation, which is to comply with the requirements of Appendix 1 of this Chapter. Where the ship length is less than 150 m, other approved equivalent direct calculation methods may be used. Attention is to be given to alignment of the floors when cut apart in way of girders so as to ensure the transverse continuity.

5.4.3.5 Vertical stiffeners are to be provided between bottom longitudinals and inner bottom longitudinals in way of solid floors.

5.4.4 Bilge brackets

5.4.4.1 Where longitudinal bottom and side framing is adopted and no longitudinals are fitted at bilge, an appropriate number of centre bilge brackets are to be provided at bilge between solid floors and connected to longitudinals at upper and lower turns of bilge. The spacing S between bilge brackets and solid floors or between bilge brackets is not to be greater than that obtained from the following formula:

$$S = 8 \times 10^6 \frac{t^2}{Dr}\sqrt{\frac{t}{r}} \quad \text{mm}$$

where: t — thickness of bilge strake, in mm;
D — moulded depth, in m;
r — radius of bilge, in mm.

The thickness of bilge brackets is to be the same as that of solid floors.

5.4.5 Bottom longitudinals

5.4.5.1 The maximum spacing of bottom longitudinals is not to be greater than 1 m.

5.4.5.2 The section modulus W of bottom longitudinals is not to be less than that obtained from the following formula:

$$W = 11.5sdl^2K \quad \text{cm}^3$$

where: s — spacing of longitudinals, in m;
d — draft, in m;
l — span of longitudinal, in m;
K — material factor.

5.4.5.3 Where penetrating non–watertight floors, the longitudinals are to be welded to the floors and vertical stiffeners on the floors.

Where a longitudinal is cut at watertight floors, the longitudinal is to be bracketed to the watertight floors. The size of the brackets is to comply with the requirements in 1.2.6 of this PART. For ships over 190 m in length or where higher tensile steel is adopted for longitudinals, the bottom longitudinals are to penetrate watertight floors, but an appropriate equivalent structure may be adopted as an alternative.

5.4.6 Inner bottom plating and inner bottom longitudinals

5.4.6.1 The thickness t of inner bottom plating is not to be less than that obtained from the following formula:

$$t_1 = \frac{s}{70\sqrt{K}} \times 10^3 \quad \text{mm}$$

where: s — spacing of inner bottom longitudinals, in m;
K — material factor. For higher strength steels, if the material factor of lower strength level could meet the requirements of buckling check for direct strength calculation, the value K of lower strength level may be taken;

$$t_2 = 4s\sqrt{hK} + 2.5 \quad \text{mm}$$

where: K — material factor;
h — vertical distance between inner bottom plating in way of longitudinal centerline and top of the tank, in m.

5.4.6.2 Inner bottom longitudinals and the corresponding bottom longitudinals are to be in the same

vertical section.

5.4.6.3 The section modulus W of inner bottom longitudinals is not to be less than that obtained from the following formula:

$$W = 8.4s\,(h + 1.2)\,l^2K \quad \text{cm}^3$$

where: s, h — see 5.4.6.1 of this Section;
l — span of longitudinals, in m;
K — material factor.

5.4.7 Sloping plating and slope plating longitudinals of hopper tanks

5.4.7.1 The thickness of sloping plating of hopper tanks is not to be less than those obtained from the following formula, and is not to be less than that of the adjacent inner hull plating:

$$t_1 = \frac{s}{70\sqrt{K}} \times 10^3 \quad \text{mm}$$

where: s — spacing of sloping plating longitudinals, in m;
K — material factor. For higher strength steels, if the material factor of lower strength level could meet the requirements of buckling check for direct strength calculation, the value K of lower strength level may be taken;

$$t_2 = 4s\sqrt{hK} + 2.5 \quad \text{mm}$$

where: K — material factor;
h — vertical height, in m, measured from lower edge of strake to the tank top in way of longitudinal centerline.

5.4.7.2 The section modulus of slope plating longitudinals is not to be less than that obtained from the following formula, and not to be less than that of the adjacent inner hull plating longitudinals:

$$W = 8.4s\,(h + 1.2)\,l^2K \quad \text{cm}^3$$

where: s — spacing of sloping plating longitudinals, in m;
h — vertical height, in m, measured from sloping plating longitudinals to the tank top in way of longitudinal centerline;
K — material factor.

Section 5 DOUBLE HULL CONSTRUCTION

5.5.1 General requirements

5.5.1.1 This Section applies to the determination of arrangement and scantlings of frames in double hull within the cargo tank region of double hull oil tankers.

5.5.1.2 Manholes are to be provided in transverse bulkheads and horizontal girders. The manholes may either be round or elliptical. The long axis of elliptical manholes is to be vertical to or along the length of the ship. Except for access openings, the holes on upper and lower adjacent horizontal girders are in general not to be on the same vertical line. The edge around the holes is to be strengthened.

5.5.1.3 For double hull oil tankers with the wing tanks as the ballast tanks, the inner hull structures are to comply with the requirements for deep tanks in Section 13, Chapter 2 of this PART.

5.5.2 Structural arrangement of double hull

5.5.2.1 Longitudinal continuous horizontal girders within double hull structures are to be provided at the same height as the transverse bulkhead horizontal girders of cargo tanks. A horizontal girder is to be provided at the top of the hopper tank (manhole may not be provided on the longitudinal girder for the sake of stability). The horizontal girders in wing ballast tanks, on cargo tank transverse bulkheads and on longitudinal bulkheads are to form a horizontal ring structure.

5.5.2.2 Transverse frames or transverse webs are to be provided in wing ballast tanks in line with the transverse bulkheads of cargo tanks.

5.5.2.3 Transverse frames or transverse webs are to be spaced not more than $0.006L + 3.2$ m apart and fitted in wing ballast tanks in line with double bottom transverses. Transverse frames or vertical webs, together with deck transverses of cargo tanks, vertical webs of longitudinal bulkheads, cross ties between inner hull and longitudinal bulkheads or between longitudinal bulkheads (if provided, see Figure 5.1.5.2(2)) of Section 1 of this Chapter) and double bottom transverses, are to form a transverse ring structure.

5.5.3 Side longitudinals

5.5.3.1 The section modulus W of side longitudinals is not to be less than that obtained from the

following formula:

$$W = 7.2s\,(h+1.2)\,l^2K \quad \text{cm}^3$$

where: s — spacing of longitudinals, in m;
h — vertical distance, in m, measured from longitudinals under consideration to deck at side amidships, but to be taken as not less than $0.25D$;
l — span of longitudinal, in m;
D — moulded depth, in m;
K — material factor.

5.5.3.2 For ships over 150 m in length or where higher tensile steel is adopted for longitudinals, the side longitudinals within $0.1D$ from bottom and strength deck are to penetrate continuously watertight transverse bulkheads.

Where side longitudinals are cut at watertight transverse bulkheads, they are to be bracketed to transverse bulkheads. The brackets are to have face plates and their arm length is to be increased by 20% over that required in 1.2.6 of Chapter 1 of this PART. Where the face plate is flanged, the breadth of the flange is not to be less than 8 times its thickness.

5.5.4 Side frames

5.5.4.1 The section modulus W of side frames is not to be less than that obtained from the following formula:

$$W=7.2s\,(h+1.2)\,l^2K \quad \text{cm}^3$$

where: s — spacing of frames, in m;
h — vertical distance, in m, measured from frames under consideration to deck at side amidships, but to be taken as not less than $0.25D$;
l — span of frame, in m, but not to be less than 2.5 m;
D — moulded depth, in m;
K — material factor.

5.5.4.2 Brackets are to be provided at both ends of side frame. The scantlings of bracket are to comply with the requirements of 1.2.6 of this PART.

5.5.5 Inner hull plating and its stiffeners

5.5.5.1 The inner hull plating is to extend as deep as possible at side or from top of the double bottom to the uppermost deck. The inner hull plating is to be so arranged that all cargo tanks are at the inner side of wing ballast tanks, and the inner shell is to extend as far forward and aft as practicable and effectively connected to the structures in way with adequate transition arrangements.

5.5.5.2 The thickness of inner hull plating is not to be less than that obtained from the following formula:

$$t = 3.75s\sqrt{hK} + 2.5 \quad \text{mm}$$

where: s — spacing of stiffeners, in m;
h — vertical distance, in m, measured from lower edge of strake to the tank top in way of longitudinal centerline, but not less than $0.4D$;
K — material factor;
D — moulded depth, in m.

5.5.5.3 The spacing of inner hull longitudinals is to be the same as that of side longitudinals. The section modulus W of longitudinals is to comply with the requirements of 5.8.4.4, Section 8 of this Chapter.

5.5.5.4 For ships over 150 m in length or where higher tensile steel is adopted for longitudinals, the inner hull longitudinals within $0.1D$ from bottom and deck are to penetrate continuously webs. Where longitudinals are cut at such webs, they are to be bracketed to the webs. The scantlings of the brackets are to comply with the requirements of 5.5.3.2 of this Section.

5.5.5.5 The section modulus W of vertical stiffeners of inner hull plating is to meet the requirements of 5.8.3.3 of Section 8 of this Chapter.

5.5.5.6 Brackets are to be provided at both ends of vertical stiffeners. The scantlings of brackets are to be comply with the requirements of 1.2.6 of this PART.

5.5.6 Horizontal girders

5.5.6.1 The thickness t of non-watertight horizontal girders within double hull structures that are provided at the same height as the transverse bulkhead horizontal girders of cargo tanks is to comply with the requirements of 5.1.6, Section 1 of this Chapter.

5.5.6.2 The scantlings of longitudinals of horizontal girders are to comply with the requirements of 5.12.2.5 of this Chapter.

5.5.6.3 On the horizontal girders, stiffeners are to be provided between side frames and vertical stiffeners of inner hull plating. The scantlings of stiffeners are to meet the requirements of 5.12.2.5 of this Chapter.

5.5.7 Transverse webs in double hull

5.5.7.1 Watertight transverse webs and stiffeners in double hull are to comply with the requirements for deep tanks as specified in Section 13, Chapter 2 of this PART.

5.5.7.2 Side longitudinals and inner hull longitudinals penetrating watertight transverse webs are to comply with the requirements of 5.5.3.2 and 5.5.5.4 of this Section. Stiffeners are to be provided on transverse webs between side longitudinals and inner hull longitudinals.

5.5.7.3 Non-watertight transverse webs supporting side longitudinals and inner hull longitudinals in double hull are to be provided in line with double bottom transverses. The thickness of non-watertight transverse webs is to comply with the requirements of 5.1.6, Section 1 of this Chapter. The side longitudinals and inner hull longitudinals are to penetrate such transverse webs. Compensation plates are to be provided at the openings to connect longitudinals and transverse structures. Stiffeners are to be provided on transverse webs between side longitudinals and inner hull longitudinals.

Section 6 DECK FRAMING

5.6.1 General provisions

5.6.1.1 This Section applies to arrangement method and scantling determination of longitudinal deck framing within cargo oil tanks of double hull oil tankers.

5.6.2 Deck transverses

5.6.2.1 Deck transverses are to be fitted in every plane of the bottom transverses.

5.6.2.2 The section modulus W of deck transverses is not to be less than that obtained from the following formula:

$$W = CLS(l + 1)K \quad \text{cm}^3$$

where: C — coefficient, $C = 1.80$ for centre oil tanks, $C = 1.92$ for wing oil tanks;

S — spacing of deck transverses, in m;

L — length of ship, in m, to be taken as not less than 65 m, but need not be more than 190 m;

l — span of deck transverse, in m;

K — material factor.

5.6.2.3 The section moment of inertia I of the deck transverse is not to be less than that obtained from the following formula:

$$I = 7.5Wl/K \quad \text{cm}^4$$

where: W, l and K — as defined in 5.6.2.2 of this Section.

In addition, the web depth of deck transverses mentioned above is not to be less than 2.5 times the depth of the cut-outs for the passage of deck longitudinals.

5.6.2.4 Stiffeners normal to the face plate are to be fitted on the web plate of deck transverses at alternate longitudinals. Where the web depth of deck transverses exceeds $210t\sqrt{K}$ (t being the thickness of the web plate and K being material factor), an additional horizontal stiffener is to be fitted at a distance of 1/4 web depth from the face plate. The scantlings of stiffeners are to comply with the requirements of 5.12.2.5 of this Chapter.

Tripping brackets, spaced not more than 4.5 m or 20 times the width of the face plate (whichever is the lesser) apart, are generally to be fitted close to the toes of end brackets of deck transverses and elsewhere. The tripping brackets is to comply with the requirements of 1.2.5.4, Chapter 1 of this PART.

5.6.2.5 Deck transverses are to be connected by end brackets to inner hull plating, longitudinal bulkheads, side framing and continuous deck girders. The scantlings of the brackets are to comply with the requirements of 1.2.7, Chapter 1 of this PART. Where connected to continuous deck girders, the brackets are to extend to the face plate of girders and to be welded to it.

5.6.3 Deck girders

5.6.3.1 The section modulus W of the continuous deck girders is not to be less than that obtained from the following formula:

$$W = 0.1Lbl^2K \quad \text{cm}^3$$

where: L — length of ship, in m;

b — mean width of load-bearing area of the continuous deck girders, in m;

l — span of the continuous deck girder, in m;
K — material factor.

5.6.3.2 Where the web height of continuous deck girders are greater than $65t\sqrt{K}$ (where t is web thickness, K is material factor), they are to be stiffened parallel to the girder face plate. The stiffeners are to comply with the requirements of 5.12.2.5 of this Chapter.

Tripping brackets are to be fitted to the continuous deck girders in accordance with the requirements of 1.2.5.4, Chapter 1 of this PART.

5.6.3.3 The connection of deck girders to transverse bulkheads or to the vertical webs on transverse bulkheads is to comply with the requirements of 1.2.7, Chapter 1 of this PART.

5.6.4 Deck longitudinals

5.6.4.1 The section modulus W of deck longitudinals is not to be less than that obtained from the following formula:

$$W = csl^2K \quad \text{cm}^3$$

where: s — spacing of longitudinals, in m;
l — span of longitudinal, in m, but not to be less than 2.5 m;
c — coefficient, to be taken as the greater of the following values: $c = 0.35L$ or $c = 0.12L + 12.6$, where L being the length of ship, in m; for L >190 m, to be taken as 190 m;
K — material factor.

5.6.4.2 Deck longitudinals, in association with the deck plating, may be gradually tapered outside $0.4L$ amidships towards the ends. At $0.075L$ from ends, the section modulus of deck longitudinals is not to be less than 80% of the value obtained from 5.6.4.1 of this Section and in addition, not to be less than that required in 2.8.5.1, Chapter 2 of this PART for deck longitudinals at the ends of ships.

5.6.4.3 Connections of deck longitudinals to transverse bulkheads are to provide adequate fixity and continuity of longitudinal strength. For ships over 150 m in length or where higher tensile steel is adopted for deck longitudinals, the longitudinals are to be continuous through the transverse bulkheads.

Where the deck longitudinals are cut in way of the transverse bulkheads, they are to be bracketed to the bulkheads, and the scantlings of the brackets are to comply with the relevant provisions in 1.2.6, Chapter 1 of this PART. Where flanged face plates are used for the brackets, the breadth of the flange is not to be less than 8 times its thickness.

Deck longitudinals are to be welded to the web of deck transverses, and to be welded to the stiffeners of deck transverses when intersecting the stiffeners.

Section 7 PLANE TRANSVERSE OILTIGHT BULKHEADS

5.7.1 General requirements

5.7.1.1 The stiffening on the plane transverse bulkheads, in general, may be arranged vertically in association with horizontal girders or horizontally in association with vertical webs.

5.7.1.2 Horizontal girders of transverse bulkheads are to be fitted in line with the horizontal girders in double hull and with horizontal girders of longitudinal bulkheads. The vertical stiffeners are to be fitted on the same longitudinal section as bottom and inner bottom longitudinals.

5.7.1.3 Vertical webs, if fitted, are to be fitted on the same longitudinal section as deck girders and bottom girders. The horizontal stiffeners are to be fitted at the same level as side longitudinals and inner hull longitudinals.

5.7.2 Thickness of bulkhead plating

5.7.2.1 The thickness t of the bulkhead plating is not to be less than that obtained from the following formula:

$$t = 3.75s\sqrt{hK} + 2.5 \quad \text{mm}$$

where: s — spacing of stiffeners, in m;
h — vertical distance, in m, measured from lower edge of strake to the tank top in way of longitudinal centerline, but not less than $0.4D$;
K — material factor.

5.7.2.2 The thickness t of the bulkhead plating is to comply with the following requirements:

(1) Where horizontal girders and vertical stiffeners are fitted on the bulkhead:

$$t \geq \frac{s}{70\sqrt{K}} \quad \text{mm, for the upper 3/4 of the bulkhead}$$

$$t \geq \frac{s}{60\sqrt{K}} \quad \text{mm, for the lower 1/4 of the bulkhead}$$

(2) Where vertical webs and horizontal stiffeners are fitted on the bulkhead:

$$t \geq \frac{s}{85\sqrt{K}} \quad \text{mm, for the upper 3/4 of the bulkhead}$$

$$t \geq \frac{s}{70\sqrt{K}} \quad \text{mm, for the lower 1/4 of the bulkhead}$$

where: s — spacing of stiffeners, in m;

K — material factor. In the case of higher tensile steel where the material factor for a lower strength level can still satisfy the requirements for plate buckling check (see also 1.5.9, Chapter 1 of this PART) in direct calculation, the value of K for a lower strength level may be taken.

5.7.3 Horizontal girders and vertical stiffeners

5.7.3.1 The section modulus W of horizontal girders is not to be less than that obtained from the following formula:

$$W = 10.5b\,(h + 1.2)\,l^2K \quad \text{cm}^3$$

where: b — width of plating supported by the girder, i.e. half the sum of the lengths of the intersected vertical stiffener above and below the horizontal girder, in m;

h — vertical distance, in m, measured from horizontal girder to the tank top in way of longitudinal centreline;

l — span of horizontal girder, in m;

K — material factor.

The web depth of the horizontal girder is not to be less than 2.5 times the depth of the cut-outs for the passage of vertical stiffeners.

5.7.3.2 Where the horizontal girders together with the horizontal girders on longitudinal bulkheads and the horizontal girders in double hull do not form a ring structure, the brackets at both ends of the horizontal girders are to extend to the adjacent vertical web or webs. The thickness of the brackets is to be the same as the web thickness of the horizontal girders, and the face plate of the brackets is to be the same as that of the horizontal girders.

5.7.3.3 End brackets, which are to comply with the requirements of 1.2.7 of Section 2, Chapter 1 of this PART, are to be fitted at both ends of horizontal girders. Supporting brackets are to be additionally fitted at the other side of the bulkhead in line with the end brackets.

5.7.3.4 Tripping brackets, spaced not more than 4.5 m or 15 times the width of the face plate (whichever is the lesser) apart, are generally to be fitted close to the toes of end brackets of horizontal girders and elsewhere. The tripping brackets are to comply with the requirements of 1.2.5.4, Chapter 1 of this PART.

5.7.3.5 The web thickness of horizontal girders is not to be less than s/80 (s being the spacing of stiffeners, in m). Stiffeners normal to the face plate are to be fitted on one side of every vertical stiffener on the web plate of horizontal girders. Where the web depth of horizontal girders exceeds 165t (t being the thickness of the web plate), an additional stiffener is to be fitted parallel to and at a distance of 1/4 web depth from the face plate.

5.7.3.6 Where continuous deck girders are fitted in way of the longitudinal centreline on deck, a vertical centreline web is also to be fitted. The scantlings are to be determined by direct calculation. The connection between them is to comply with the requirement of 1.2.7, Chapter 1 of this PART.

5.7.3.7 The section modulus W of vertical stiffeners is not to be less than that obtained from the following formula:

$$W = 7.2s\,(h + 1.2)\,l^2K \quad \text{cm}^3$$

where: s — spacing of stiffeners, in m;

h — vertical distance, in m, measured from mid- span of stiffeners to the tank top in way of longitudinal centerline, but to be taken as not less than 0.25D;

l — span of stiffener, in m;

K — material factor.

5.7.3.8 The stiffeners are to be connected to the inner bottom and deck longitudinals by brackets at both ends. The brackets are to comply with the requirements of 1.2.6, Chapter 1 of this PART. The stiffeners are to be welded to the web of horizontal girders and vertical stiffeners on the web when penetrating horizontal girders.

5.7.4 Vertical webs and horizontal stiffeners

5.7.4.1 The section modulus W of vertical webs is not to be less than that obtained from the following formula:

$$W = Cb\,(h + 1.2)\,l^2K \quad \text{cm}^3$$

where: b — width of plating supported by the vertical web, i.e. half the total length of the horizontal stiffener intersecting the vertical web, in m;

h — vertical distance, in m, measured from mid- span of the vertical web to the tank top in way of longitudinal centreline;

l — span of vertical web, in m;

C — coefficients: $C = 11$, for the vertical web at the centreline; $C = 8.8$, for the vertical web not on the centreline but supporting the horizontal stiffeners;

K — material factor.

The web depth of vertical webs is not to be less than 2.5 times the depth of the cut-outs for the passage of horizontal stiffeners.

5.7.4.2 Where vertical webs, bottom girders and deck girders do not form a ring structure, the brackets at both ends of the vertical web are to extend to the adjacent deck transverse or bottom transverse. The thickness of the brackets is to be the same as the web thickness of the vertical webs, and the face plate of the brackets is to be the same as that of the vertical webs, or an alternative effective structural configuration is to be adopted to ensure the continuity of the structure.

5.7.4.3 End brackets, which are to comply with the requirements of 1.2.7 of Section 2, Chapter 1 of this PART, are to be fitted at both ends of the vertical webs. Supporting brackets are to be additionally fitted at the other side of the bulkhead in line with the end brackets.

5.7.4.4 Tripping brackets, spaced not more than 4.5 m or 15 times the width of the face plate (whichever is the lesser) apart, are generally to be fitted close to the toes of end brackets of vertical webs and elsewhere. The tripping brackets are to comply with the requirements of 1.2.5.4, Chapter 1 of this PART.

5.7.4.5 Vertical webs are to be fitted with stiffeners parallel to the girder face plate and spaced not more than 60 $\sqrt{K}$ (K being material factor) times the web thickness apart. When horizontal stiffeners on transverse bulkheads are supported by vertical girders, stiffeners normal to the face plate are to be fitted at every horizontal stiffener. The scantlings of stiffeners are to comply with the requirements of 5.12.2.5 of this Chapter.

5.7.4.6 The section modulus W of horizontal stiffeners is not to be less than that obtained from the following formula:

$$W = 7.2s\,(h + 1.2)\,l^2K \quad \text{cm}^3$$

where: s — spacing of stiffeners, in m;

h — vertical distance, in m, measured from the stiffener to the tank top in way of longitudinal centreline, but not to be less than $0.25D$, in m;

l — span of stiffener, in m;

K — material factor.

5.7.4.7 The stiffeners are to be connected to the inner hull and the horizontal stiffeners of longitudinal bulkheads by brackets having the scantlings as required in 1.2.6, Chapter 1 of this PART. Horizontal stiffeners are to be welded to the web plate and stiffeners of the vertical webs.

Section 8 PLANE LONGITUDINAL OILTIGHT BULKHEADS

5.8.1 General requirements

5.8.1.1 Longitudinal bulkheads are to be continuous throughout all cargo tanks, and are to extend as far forward and aft as possible. Where the longitudinal bulkheads are cut, large brackets or other longitudinal transitional members are to be fitted to ensure effective continuity.

5.8.1.2 The stiffening on the longitudinal bulkheads may be arranged vertically in association with horizontal girders or horizontally in association with vertical webs. Horizontal girders are to be fitted at the same level as those of transverse bulkheads, and vertical stiffeners are to be fitted on the transverse section of transverse frames. Vertical webs are to be fitted on the same transverse section as bottom floors, and horizontal stiffeners are to be fitted at the same level as side longitudinals.

5.8.1.3 Continuous girders are to be fitted in double bottom at plane longitudinal bulkheads.

5.8.2 Thickness of bulkhead plating

5.8.2.1 The thickness t of the longitudinal bulkhead plating is not to be less than that obtained from the following formula:

$$t = 3.75s\sqrt{hK} + 2.5 \quad \text{mm}$$

where: s — spacing of stiffeners, in m;

h — vertical distance, in m, measured from the lower edge of strake to the tank top in way of longitudinal centreline; but not less than $0.4D$, in m;

K — material factor;

D — moulded depth of ship, in m.

5.8.2.2 The thickness of the longitudinal bulkhead plating within $0.1D$ from deck need not exceed the sheer strake thickness with the same frame spacing.

5.8.3 Horizontal girders and vertical stiffeners

5.8.3.1 The section modulus of horizontal girders is to be calculated in accordance with 5.7.3.1 of this Chapter and to comply with relevant requirements, but the span under consideration is not to be less than 3 m.

5.8.3.2 Horizontal girders and those of transverse bulkheads are to be connected as required in 1.2.7 of this PART.

5.8.3.3 The section modulus W of vertical stiffeners is not to be less than that obtained from the following formula:

$$W = 7.2s\,(h + 1.2)\,l^2K \quad \text{cm}^3$$

where: s, h, l and K are the same as that in 5.7.3.7 of this Chapter.

5.8.3.4 Stiffeners are to be bracketed at both ends. These brackets are to extend to the nearest inner bottom and deck longitudinals and the scantlings of these brackets are to comply with the requirements of 1.2.6 of this PART, but the depth of the lower bracket along the stiffener is not to be less than 15% of the distance between the ship's bottom and the adjacent horizontal girder. Vertical stiffeners are to be welded to the web plate and stiffeners of the horizontal girders.

5.8.4 Vertical webs and horizontal stiffeners

5.8.4.1 Where one longitudinal bulkhead is fitted, vertical webs symmetrical to the longitudinal centerline are to be fitted in line with floors. The vertical webs may also to be fitted at one side of the longitudinal bulkhead. Where two longitudinal bulkheads are fitted, vertical webs are to be fitted in compartments with cross ties.

5.8.4.2 The section modulus of vertical webs is not to be less than that obtained from the following formula:

$$W = CS\,(h + 1.2)\,l^2K \quad \text{cm}^3$$

where: S — spacing of vertical webs, in m;

h — vertical distance, in m, measured from the mid-span of vertical webs to tank top;

l — span of vertical webs, in m;

C — coefficient: C = 11, without horizontal cross tie; C = 3.2, with 1 horizontal cross tie; C = 3, with 2 horizontal cross ties;

K — material factor.

5.8.4.3 The end brackets of vertical webs are to comply with the requirements of 1.2.7, Chapter 1 of this PART.

5.8.4.4 The section modulus W of horizontal stiffeners is not to be less than that obtained from the following formula:

$$W = 7.2s\,(h + 1.2)\,l^2K \quad \text{cm}^3$$

where: s — spacing of stiffeners, in m;

h — vertical distance, in m, measured from stiffeners to tank top at longitudinal centerline, but not less than $0.25D$;

l — span of stiffener, in m;

K — material factor.

5.8.4.5 For ships over 150 m in length or where higher tensile steel is adopted, the horizontal stiffeners on longitudinal bulkheads within $0.1D$ from bottom and deck are to be continuous through transverse bulkheads. Where the horizontal stiffeners are cut at the transverse bulkheads, they are to be bracketed to the transverse bulkheads. Where the transverse bulkheads are stiffened vertically, the brackets at the ends of horizontal stiffeners are to extend to the nearest vertical stiffeners of the transverse bulkheads; the scantlings of the brackets are to be in accordance with the requirements of 5.5.3.2 of this Chapter.

Horizontal stiffeners are to be welded to the web plate and stiffeners of the vertical webs.

5.8.5 Cross ties

5.8.5.1 In oil tankers having two longitudinal bulkheads, horizontal cross ties are to be arranged in the transverse ring structure as shown in Figure 5.1.5.2(2). The cross ties are to be located as follows: where one horizontal cross tie is arranged, the centerline of the cross tie is to be between 0.5D and 0.7D from deck; where two horizontal cross ties are arranged, the centerline of the upper one is to be between 0.4D and 0.5D from deck, while the centerline of the lower one is to be between 0.7D and 0.8D from deck. Cross ties may be omitted in transverse ring structures adjacent to watertight transverse bulkheads.

5.8.5.2 The sectional area A and section moment of inertia I of the horizontal cross ties are not to be less than those obtained from the following formulae:

$$A = 1.1Kbs(h + 1.2) + 50K \quad \text{cm}^2$$

$$I = 2.1bs\ (h + 1.2)\ l^2 \quad \text{cm}^4$$

where: b — width of plating supported, in m, taken as half of the moulded depth when one cross tie is arranged or half the distance from deck or bottom to the adjacent cross tie when two cross ties are arranged;

h — vertical distance, in m, measured from the centerline of the cross tie to deck at side;

s — spacing of transverse ring structures, in m;

K — material factor;

l — length of cross ties, in m.

5.8.5.3 Substantial vertical and horizontal brackets are to be fitted at ends of cross ties for connection of cross ties to the vertical webs of inner hull and longitudinal bulkheads. The vertical brackets are to be in line with the cross tie web plates, and the horizontal brackets are to be in line with the cross tie face plates.

5.8.5.4 Stiffeners parallel to the face plate are to be fitted on the web plate of cross ties. Where $L \leq 90$ m, the distance between the stiffener and the face plate or between two stiffeners is not to exceed 80 $t\sqrt{K}$ (t being the thickness of cross tie webs, K being material factor); where $L \geq 190$ m. the distance is not to exceed 55 $t\sqrt{K}$. Intermediate values are to be obtained by interpolation.

Brackets are to be fitted on the web plate of cross ties to support the face plate and horizontal stiffeners.

5.8.5.5 Cross ties are to be subject to buckling check.

Section 9 CORRUGATED TRANSVERSE OILTIGHT BULKHEADS

5.9.1 General requirements

5.9.1.1 Except where otherwise specified, the symbols for dimensions of corrugations are shown in Figure 1.2.4.3 of Chapter 1 of this PART.

5.9.1.2 Vertical corrugations are generally to be adopted for corrugated transverse bulkheads except in special cases. The angle between flange and web portions of the corrugation is not to be less than 40º.

5.9.1.3 For oil tankers of 190 m or over in length, lower stools and in general, upper stools are to be provided for vertical corrugated bulkheads.

5.9.2 Corrugation dimensions and bulkhead plating

5.9.2.1 The thickness of transverse corrugated bulkheads is to be determined according to 5.7.2.1 of this Chapter. In calculation, s is to be taken as the width of corrugation flange or that of corrugation web, whichever is the greater, and is to comply with the following formula:

$$t \geq \frac{s}{70\sqrt{K}} \quad \text{mm}$$

where: s — the width of corrugation flange or that of corrugation web, in mm, whichever is the greater;

K — material factor. In the case of higher tensile steel where the material factor for a lower strength level can still satisfy the requirements for plate buckling check (see also 1.5.9, Chapter 1 of this PART) in direct calculation, the value of K for a lower strength level may be taken.

5.9.2.2 The section modulus W and moment of inertia I of a corrugation of bulkheads are not to be less than those obtained from following formulae respectively:

$$W = 8.8s\ (h + 1.2)\ l^2K \text{ cm}^3$$

$$I = 3.2Wl/K \quad \text{cm}^4$$

where: s — breadth of a corrugation, in m;

h — vertical distance, in m, measured from the mid- span of the corrugation to the tank top in way of longitudinal centerline;

l — span of corrugation, in m;

K — material factor.

5.9.3 Lower stools

5.9.3.1 Lower stools are to comply with the requirements of 8.9.4.1 of this PART.

5.9.3.2 Where the spacing of longitudinal girders in double bottom under the lower stool is greater than 3.8 m, local girders are to be provided. Longitudinal webs are to be provided at center girders, side girders and local girders in the lower stool.

5.9.4 Upper stools

5.9.4.1 Upper stools are to comply with the requirements of 8.9.4.1 of this PART.

5.9.5 Arrangement of structure with no lower stool or upper stool

5.9.5.1 Where no upper stool or lower stool is fitted, the upper and lower structures of transverse bulkheads are to be arranged as required in 8.9.4.1 of this PART.

5.9.6 Horizontal girders

5.9.6.1 Where horizontal girders are provided for corrugated transverse bulkheads, the scantlings and structures of the horizontal girders are to comply with the requirements for plane bulkhead horizontal girders specified in 5.7.3 of this Chapter.

5.9.6.2 The considered depth of the web of horizontal girders is to be taken as the minimum distance between the face plate and the bulkhead.

Section 10 CORRUGATED LONGITUDINAL OILTIGHT BULKHEADS

5.10.1 General requirements

5.10.1.1 Except where otherwise specified, the symbols for dimensions of corrugations are shown in Figure 1.2.4.3 of Chapter 1 of this PART.

5.10.1.2 The angle between web and flange of the corrugation is generally not to be less than 40º.

5.10.1.3 Corrugated longitudinal bulkheads are not recommended for oil tankers of 190 m or over in length.

5.10.1.4 Corrugated longitudinal bulkheads may be horizontally or vertically corrugated. Any arrangement, with both longitudinal and transverse bulkheads being horizontally corrugated, is to be avoided.

5.10.2 Vertically corrugated longitudinal bulkheads

5.10.2.1 The thickness of plating of corrugated longitudinal bulkheads is to comply with the requirements of 5.8.2.1 of this Chapter. In calculation, s is to be taken as the width of corrugation flange or that of corrugation web, whichever is the greater, and is to comply with the following formula:

$$t \geq \frac{s}{70\sqrt{K}} \quad \text{mm}$$

where: s — the width of corrugation flange or that of corrugation web, in mm, whichever is the greater;

K — material factor. In the case of higher tensile steel where the material factor for a lower strength level can still satisfy the requirements for plate buckling check (see also 1.5.9, Chapter 1 of this PART) in direct calculation, the value of K for a lower strength level may be taken.

5.10.2.2 The section modulus W and moment of inertia I of a corrugation of bulkheads are not to be less than those obtained from following formulae:

$$W = 8.8s\,(h + 1.2)\,l^2K \text{ cm}^3$$

$$I = 3.2Wl/K \quad \text{cm}^4$$

where: s — breadth of a corrugation, in m;

h — vertical distance, in m, measured from the mid- span of the corrugation to the tank top in way of longitudinal centerline; h is not to be less than 2.5 m;

l — span of corrugation, in m;

K — material factor.

5.10.2.3 Upper stools and lower stools are generally to be fitted at vertically corrugated longitudinal oiltight bulkheads.

5.10.2.4 The height of the lower stools is generally not to be less than 3 times the depth of the corrugations. The thickness and material grade of the stool top plate are not to be less than those required

for the bulkhead plating above. The thickness and material grade of the upper portion of vertical or sloping stool side plating, within the depth equal to the corrugation flange width from the stool top, are not to be less than the flange plate thickness and material grade needed to meet the bulkhead stiffness requirements at the lower end of the corrugation.

The distance from the edge of the stool top plate to the surface of the corrugation flange is not to be less than 1.5 times the corrugation flange plate thickness. The stool bottom is to be fitted in line with duct keels in double bottoms and is to have a width not less than 2.5 times the mean depth of the corrugation.

Vertical stiffeners are to be fitted on the lower stool side plating in line with the frames mentioned in 5.4.2.10 of this Chapter. Both ends of the stiffeners are to be bracketed to upper and lower ends of the stool.

Horizontal stiffeners, of which the moment of inertia I may be determined according to 5.12.2.5(2) of this Chapter, are also to be fitted on the lower stool side plating. Diaphragms, the thickness of which is to be the same as that of double bottom solid floors, are to be fitted inside the lower stool in line with solid floors.

Scallops in the brackets and diaphragms in way of the connections to the stool top plate are to be avoided.

5.10.2.5 The upper stool is to have a height generally between 2 and 3 times the depth of corrugations. Rectangular stools are to have a height generally equal to 2 times the depth of corrugations, but greater than the height of deck transverses. The width of the stool bottom plate is generally to be the same as that of the lower stool top plate. The top of non-rectangular stools is to have a width not less than 2 times the depth of corrugations. The side plating of the upper stool may be connected directly to the deck, and to be bracketed transversely to beams.

The thickness and material of the stool bottom plate are to be the same as those of the bulkhead plating below. The thickness of the stool side plating is not to be less than 80% of that required for the upper part of the bulkhead plating where the same material is used. Where vertical stiffeners are fitted at side plating of the upper stool, both ends of the stiffeners are to be bracketed to the upper and lower ends of the stool.

Horizontal stiffeners are also to be fitted at side plating of the upper stool. Diaphragms, the thickness of which is to be the same as that of the web of deck transverses, are to be fitted inside the stool in line with deck transverses.

Scallops in the brackets and diaphragms in way of the connection to the stool top plate are to be avoided.

5.10.2.6 If no bottom stool is fitted, the corrugation flanges are to be in line with the side plating of duct keels and connected to the inner bottom plating by full penetration welds.

5.10.2.7 Where horizontal girders are fitted, they are to comply with the requirements of 5.9.6 of this Chapter.

5.10.3 Horizontally corrugated longitudinal bulkheads

5.10.3.1 The thickness of plating of horizontally corrugated longitudinal bulkheads is to comply with the requirements of 5.8.2.1 of this Chapter. In calculation, s is to be taken as the width of corrugation flange or that of corrugation web, whichever is the greater.

5.10.3.2 The section modulus of a corrugation of the bulkhead is to be determined according to 5.10.2.2 of this Chapter.

5.10.3.3 The flat bottom of horizontally corrugated bulkheads is to be in line with longitudinal girders in double bottom and connected to the inner bottom plating by full penetration welds. The top is welded directly to deck. Both the width of bottom and top flat portion are not to be less than $0.1D$ for ships of more than 150 m in length.

5.10.3.4 Where the width of the flat bottom and top is greater than that of corrugation flange or web, an appropriate stiffening structure is to provided.

5.10.3.5 Vertical webs of horizontally corrugated bulkheads are to be fitted in line with solid floors, and are to comply with the requirements of 5.8.4 of this Chapter. The web depth of the vertical webs is to be taken as the minimum distance between the face plate of vertical webs and the bulkhead.

Section 11 NON-OILTIGHT BULKHEADS AND WASH BULKHEADS

5.11.1 General requirements

5.11.1.1 Where transverse non-oiltight or wash bulkheads are fitted in the cargo tanks, they are to have an area of perforations not less than 10% of the total area of the bulkhead, and the area of perforations is not to be more than 25% of the total area of the bulkhead for longitudinal non-oiltight bulkheads.

5.11.1.2 Where non-oiltight bulkheads support the bottom centre girder, the perforations are to be so arranged as not to impair the efficiency of the bulkhead as a support to the hull structure. Essential openings (such as openings for pipes, access, etc.) in the lower portion of bulkheads are to be circular with edge stiffening.

5.11.1.3 Non-oiltight or wash bulkheads are to be provided with access openings not less than 600 mm × 800 mm in size.

5.11.2 Bulkhead plating and stiffening

5.11.2.1 The thickness of bulkhead plating is not to be less than that required in 5.1.6 of this Chapter. The thickness of the transverse bulkhead plating supporting centre girders, in addition, is to meet the requirements of 5.7.2.2 of this Chapter and in no case are the panel dimensions to exceed 180 times the thickness of the bulkhead plating.

5.11.2.2 The net vertical sectional area A of the non-oiltight transverse bulkhead supporting centre girders is not to be less than that obtained from the following formula:

$$A = 0.14 l_x b D_x K \quad \text{cm}^2$$

where: l_x — the distance, in m, between the bulkheads (oiltight or non-oiltight) adjacent to the non-oiltight bulkhead under consideration;

b — overall breadth of oil tank, in m;

D_x — actual depth of non-oiltight transverse bulkheads or transverse wash bulkheads, in m;

K — material factor.

5.11.2.3 The section modulus W of stiffeners is not to be less than that obtained from the following formula:

$$W = 125 s l^2 K \frac{l_x}{L} \quad \text{cm}^3$$

where: s — spacing of stiffeners, in m;

l — span of stiffener, in m;

K — material factor;

l_x — see 5.11.2.2 of this Section;

L — length of ship, in m.

5.11.2.4 Stiffeners are to be bracketed at their ends. The scantlings of the brackets are to comply with the requirements of 1.2.6, Chapter 1 of this PART.

5.11.3 Vertical webs and horizontal girders

5.11.3.1 Horizontal girders, vertical webs or stiffeners are to be fitted on the non-oiltight or wash bulkheads in line with the strength members which are supported by the bulkheads.

5.11.3.2 The section modulus of vertical webs is not to be less than one half of that required for the vertical webs of oiltight bulkheads arranged in the same way.

5.11.3.3 The section modulus W of horizontal girders is not to be less than that obtained from the following formula:

$$W = 150 b l^2 K \frac{l_x}{L} \quad \text{cm}^3$$

where: b — width of plating supported by the girder, in m, i.e. half the sum of the lengths of the intersected stiffener above and below the girder, in m;

l — span of girder, in m;

K — material factor;

l_x — see 5.11.2.2 of this Section;

L — length of ship, in m.

Section 12 SPECIAL REQUIREMENTS

5.12.1 General requirements

5.12.1.1 The symmetrical section is to be adopted as far as applicable for side longitudinals and inner hull longitudinals between 2 m below the ballast waterline and 2 m above the full-loaded waterline. The symmetrical section is also recommended for longitudinals within the above-mentioned extent of longitudinal bulkheads to avoid additional torsional stress. Where higher tensile steel is adopted for side longitudinals and vertical stiffeners or brackets on primary transverse structural webs are connected directly to side longitudinals, the toes of stiffeners or brackets within the above-mentioned extent are to be well radiused (see Figure 5.12.1.1). Where CCS fatigue assessment requirements are complied with, other structural arrangements will be considered.

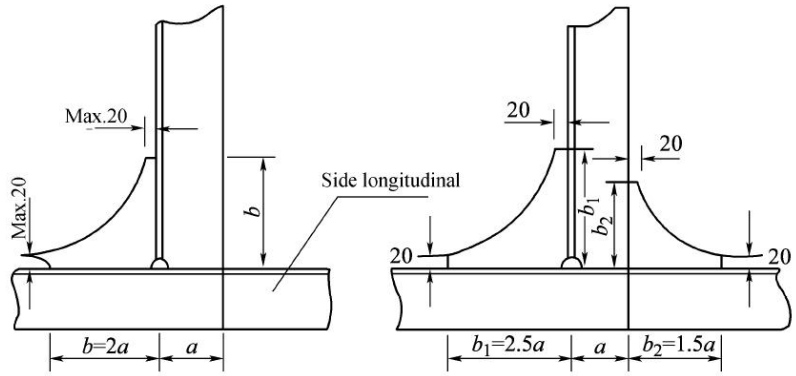


Figure 5.12.1.1

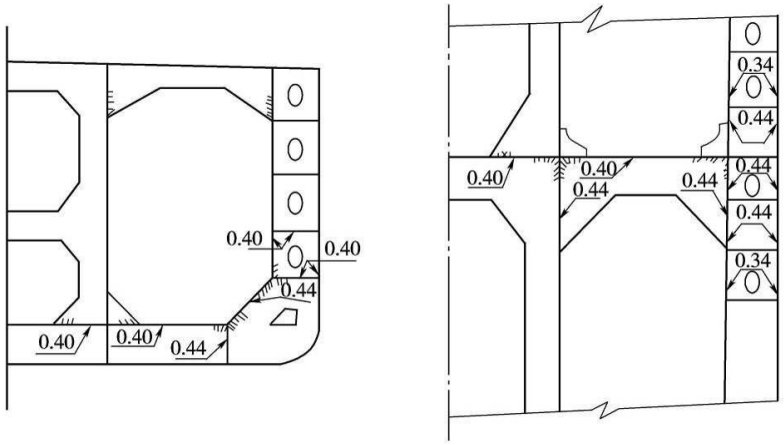
5.12.1.2 Where side longitudinals of higher tensile steel pass through watertight transverse bulkheads in the cargo tank region, radiused brackets of the same material are to be fitted on both the fore and aft sides of the connection between the upper edge of bilge and 0.8*D* above the draft line, and attention is to be given to ensure the alignment of the brackets.

5.12.1.3 For oil tankers greater than 250 m in length, special attention is to be given to the alignment for connection of the transverse ring system and transverse bulkhead horizontal girders as shown in Figure 5.12.1.3 to relevant adjacent members and to the application of full penetration or increased throat thickness for fillet welds. The length of the increased throat thickness is not to be less than 2*s* or 1.2 m, whichever is the greater, where *s* is spacing of secondary members, in m.



Note: Deep penetration welds are required for shadow areas, and increased throat thickness based on weld factors as shown in the Figure is required for other areas.

Figure 5.12.1.3

5.12.2 Structure details

5.12.2.1 Where flat steel is adopted for longitudinals, the ratio of height to thickness is not to be greater than $18\sqrt{K}$ (*K* being material factor) for the longitudinals penetrating bulkheads and not greater than $15\sqrt{K}$ for the longitudinals cut at bulkheads. Where flat steel is adopted for stiffeners, the ratio of height to thickness is not to be greater than $18\sqrt{K}$.

5.12.2.2

(1) The diameter of lightening holes of primary members is not to be greater than 20% of the web height. The distance between the edge of the hole and face plate is not to be less than 40% of the web height, and an equal distance is in general to be kept from the edge of the hole to the corner of notches for the passage of frames. The holes are to be kept clear of notches and bracket toes. The edge of holes are to be well rounded with smooth edges.

(2) Openings with a diameter larger than that specified above are subject to check by direct calculation according to the requirements in Appendix 1 of this Chapter.

(3) Lightening holes are not to be provided on webs of primary members (e.g. side girders, longitudinal bulkhead horizontal girders) in way of cross ties and their end connections.

5.12.2.3 The holes on webs of primary longitudinal members within 0.1*D* (*D* being moulded depth) from deck and bottom are generally to be strengthened. Access holes on deep longitudinal and transverse girders

are to be provided with suitable compensation, so as to satisfy the requirement for resistance to local deformation and shear buckling in the web.

5.12.2.4 The lower edge of holes cut for oil heating piping is not to be less than 100 mm from the shell plating; where notches are cut for the passage of longitudinals, adjacent to such holes, the notches are to be collared.

5.12.2.5 The web depth of stiffeners of primary members is not to be less than 75 mm. Where stiffeners are to be provided both parallel and vertical to the face plate, the scantlings of stiffeners parallel to the face plate are not to be less than those of stiffeners vertical to the face plate. The section moment of inertia of stiffeners is to comply with the following requirements respectively:

(1) The section moment of inertia I of stiffeners vertical to the face plate of primary members is not to be less than that obtained from the following formula:

$$I = 0.175\left(\frac{h}{s}\right)^{2.4} st^3 \quad \text{cm}^4$$

where: h — spacing of horizontal stiffeners for main structural member, or depth of web without stiffeners, in m;

s — spacing of stiffeners, in m;

t — thickness of web, in mm.

In calculation, 1 is to be taken for $h/s < 1$ and 3.3 for $h/s > 3.3$.

(2) The section moment of inertia I of stiffeners parallel to the face plate of primary members is not to be less than that obtained from the following formula:

For longitudinal stiffeners:

$$I = 1.62l^2 A \quad \text{cm}^4$$

For other stiffeners:

$$I = 0.82l^2 A \quad \text{cm}^4$$

where: l — spacing of stiffeners, in m;

A — sectional area of stiffeners with attached plates, in cm².

5.12.2.6 Stiffeners are to be provided for large brackets so that the side length of the non-stiffened triangle of the bracket is not greater than 100 times the thickness of the bracket. Stiffeners are to be parallel to the face plate. The distance from the stiffeners near the face plate to the face plate is not to be greater than 30 times the thickness of the bracket. The spacing of other stiffeners may not be greater than 45 times the thickness of bracket plating. The face plate and stiffeners are to be appropriately supported against tripping. Where the face plate is non-continuous at the structural member, both ends of the face plate are to be sniped.

5.12.2.7 The height of bracket stiffeners is not to be less than 75 mm, and their section moment of inertia I is specified as follows:

For the brackets of deck stringers and keel, not to be less than:

$$I = 3l^2 A \quad \text{cm}^4$$

For those of other primary members, not to be less than:

$$I = 2l^2 A \quad \text{cm}^4$$

where: l — span of stiffeners, in m;

A — sectional area of stiffeners with attached plates, in cm².

5.12.2.8 In the cargo tank region, integral brackets with continuous face plates are to be adopted as far as practicable for end brackets of primary members. Where the thicknesses of face plates connecting two primary members are different, the primary member with the larger face plate is to have the width of its face plate being maintained to the mid-point of the free side of the bracket and gradually tapered to the smaller face plate of the other primary member. The taper is generally not to exceed 1:3 and where the width of the face plate is greater than 500 mm, the taper is not to exceed 1:4. Where a thick face plate is connected to a thinner one, the difference in thickness is not to exceed 4 mm and in the event that the difference exceeds 4 mm, the taper on thickness is to be 1:3.

Section 13 CARGO TANK HATCHWAYS

5.13.1 General requirements

5.13.1.1 Cargo tank hatchways and ladders are to be fitted in compliance with Section 12, Chapter 1 of this PART.

5.13.2 Requirements for cargo tank hatchways

5.13.2.1 The height of the hatch coaming is not to be less than 600 mm, and the thickness of the coaming plating is not to be less than 10 mm. Where the height of coaming exceeds 600 mm, the coaming is to be increased in thickness and reinforced by horizontal stiffeners on the upper portion.

5.13.2.2 The thickness of hatch covers is not to be less than 12 mm. Where the area of the cover exceeds 1.2 m^2, the cover is to be reinforced by stiffeners or increased in thickness.

5.13.2.3 Hatch covers are to be secured by bolts spaced generally not more than 460 mm apart, and not more than 230 mm from hatch corners.

5.13.2.4 Sighting ports having a diameter not less than 150 mm are to be provided in the covers. These holes are to be provided with effective closing appliances to ensure oil-tightness.

Appendix 1 DIRECT STRENGTH CALCULATION OF DOUBLE HULL OIL TANKERS

1 GENERAL

1.1 Application

1.1.1 This Appendix applies to direct calculations, required by this Chapter, of the structural strength of double hull oil tankers.

1.1.2 Where not stipulated in this Appendix, the relevant requirements of Section 5, Chapter 1 of this PART are to be complied with.

1.1.3 For partially filled cargo tanks, consideration is to be given to the sloshing strength under the sloshing pressure due to liquid motion.

2 DESIGN LOADS

2.1 General requirements

2.1.1 Unless stipulated otherwise in the Appendix, the design loads are to be referred to in Section 5, Chapter 1 of this PART.

2.1.2 Unless stipulated otherwise in the Appendix, the still water bending moment in the global load condition is to be taken as the allowable value $\overline{M}_s$ provided by the designer; the wave bending moment M_w is to be calculated according to 1.5.6.1(2) of Section 5, Chapter 1 of this PART.

2.1.3 For harbour conditions, the effect of wave loads (pressure and bending moment) is not considered; the allowable still water bending moment $\overline{M}_{sp}$ is determined by the designer, but is to envelop the design still water bending moment under the loading and unloading conditions in harbour given in the loading manual.

3 LOADING CONDITIONS

3.1 General requirements

3.1.1 Normally, the corresponding loading conditions are to be selected from Tables 3.2.1 to 3.2.3 of this Appendix for check. For other more severe loading conditions in the loading manual which are not covered by these Tables, direct strength calculation is also to be carried out.

3.2 Loading conditions

3.2.1 The loading conditions of oil tankers with one longitudinal bulkhead are referred to in Table 3.2.1. For the conditions of LC2, LC3, LC5, LC6, if the structures are not symmetrical to the longitudinal centreline, the loading conditions of tanks on starboard and port sides are to be included respectively.

Loading Conditions **Table 3.2.1**

Loading condition	Draught	Still water bending moment	Wave bending moment	Mode of loading
LC1	d	$\overline{M}_s$	M_w	LC2	d	$\overline{M}_s$	M_w	LC3	0.35D	$\overline{M}_{sp}$	–	LC4	0.35D	$\overline{M}_{sp}$	–	
Loading condition	Draught	Still water bending moment	Wave bending moment	Mode of loading
LC5	d	$\overline{M}_s$	M_w	
LC6	0.25D	$\overline{M}_{sp}$	–	LC7	Ballast draught	$\overline{M}_s$	M_w	LC8	Heavy ballast draught	$\overline{M}_s$	M_w	
3.2.2 For oil tankers with two longitudinal bulkheads, loading conditions are referred to in Table 3.2.2.

Loading Conditions **Table 3.2.2**

Loading condition	Draught	Still water bending moment	Wave bending moment	Mode of loading
LC1	d	$\overline{M}_s$	M_w	LC2	d	$\overline{M}_s$	M_w	LC3	d	$\overline{M}_s$	M_w	
LC4	0.25D	$\overline{M}_{sp}$	–	LC5	0.25D	$\overline{M}_{sp}$	–	LC6	0.35D	$\overline{M}_{sp}$	–	LC7	0.35D	$\overline{M}_{sp}$	–	
LC8	Ballast draught	$\overline{M}_s$	M_w	LC9	Heavy ballast draught	$\overline{M}_s$	M_w	
Loading condition	Draught	Still water bending moment	Wave bending moment	Mode of loading
LC10	Heavy ballast draught	$\overline{M}_s$	M_w	
3.2.3 For oil tankers without longitudinal bulkheads, loading conditions are referred to in Table 3.2.3.

Loading Conditions **Table 3.2.3**

Loading condition	Draught	Still water bending moment	Wave bending moment	Mode of loading
LC1	d	$\overline{M}_s$	M_w	
LC2	0.35D	$\overline{M}_{sp}$	–	LC3	Ballast draught	$\overline{M}_s$	M_w	LC4	Heavy ballast draught	$\overline{M}_s$	M_w	
4 STRUCTURAL MODELING

4.1 General requirements

4.1.1 Unless stipulated otherwise in this Appendix, the requirements for structural modeling are to be referred to in Section 5, Chapter 1 of this PART (for typical finite element model, see Figure 4.1.1).

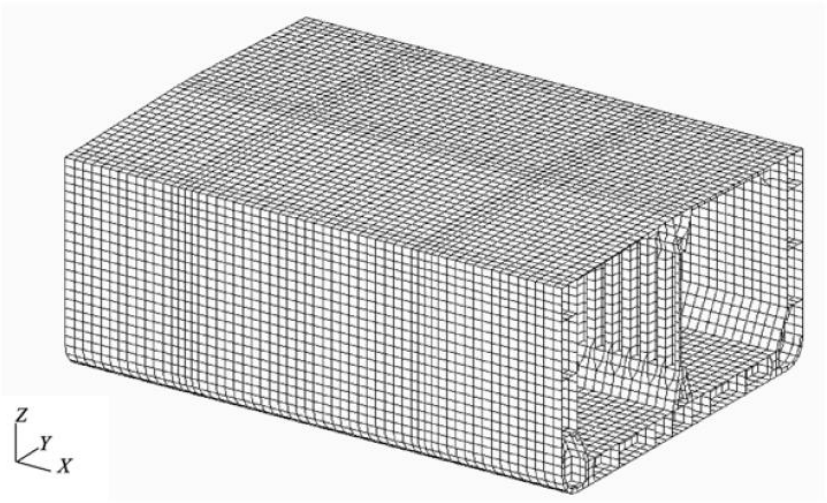

Figure 4.1.1 Finite Element Model

4.2 Boundary conditions

4.2.1 Boundary condition with the structures symmetrical to longitudinal centerline section

4.2.1.1 If a half-breadth FE model is used, the displacements in transverse direction of nodes on the longitudinal centerline section and the rotations around the two coordinate axes on the longitudinal centerline section are restrained, i.e.: $\delta_y = \theta_x = \theta_z = 0$.

4.2.1.2 If a full-breadth FE model is used, the displacements in transverse direction of intersection G of the longitudinal centerline section in way of forward and aft bulkheads of midship cargo tanks and bottom plating are restrained, i.e.: $\delta_y = 0$.

4.2.2 Boundary conditions for local loads (see Table 4.2.2)

4.2.2.1 Symmetrical conditions are applied respectively to end planes A and B, the displacements in the longitudinal direction of nodes and the rotations around the two coordinate axes within the end plane are to be restrained, i.e.: $\delta_x = \theta_y = \theta_z = 0$.

4.2.2.2 Vertical spring elements are to be provided at intersections of side shell plating, inner hull plating and longitudinal bulkhead with forward and aft bulkheads in midship cargo tanks. The coefficient of elasticity of spring elements is to be distributed evenly and calculated by the following formula:

$$K = \frac{5GA}{6l_H n} \quad \text{N/mm}$$

where: G — shear modulus of elasticity of material, $G = 0.792 \times 10^5$ N/mm^2 for steel;

A — shearing area of side shell plating, inner hull plating or longitudinal bulkhead plate in way of forward and aft bulkheads, in mm^2;

l_H — length of midship cargo tank, in mm;

n — number of nodes on vertical intersections of side shell plating, inner hull plating or longitudinal bulkhead plate.

Boundary Conditions for Local Loads **Table 4.2.2**

Position	Displacement constraint			Rotation constraint		
	δ_x	δ_y	δ_z	θ_x	θ_y	θ_z
Longitudinal centerline section (half-breadth model)	–	Constraint	–	Constraint	–	Constraint
Node *G* (full-breadth model)	–	Constraint	–	–	–	–
End planes *A*, *B*	Constraint	–	–	–	Constraint	Constraint
Intersection line *C*	–	–	Spring	–	–	–

4.2.3 Boundary conditions for global load (see Table 4.2.3)

4.2.3.1 An independent point *H* is to be set in way of intersection of the neutral axis with the longitudinal centerline section within end planes *A* and *B*, the longitudinal bending moment is to be applied on the point *H*, and the degrees of freedom δ_x, δ_y and δ_z of each member node for end planes is linked to the independent point.

4.2.3.2 The displacements of the independent point *H* within end planes *A* and *B* in transverse direction, vertical direction, and the rotation around longitudinal axes are restrained, i.e.: $\delta_y = \delta_z = \theta_x = 0$; the displacement of the independent point *H* within the end plane *A* in longitudinal direction is restrained, i.e.: $\delta_x = 0$.

Boundary Conditions for Global Load **Table 4.2.3**

Position	Displacement constraint			Rotation constraint		
	δ_x	δ_y	δ_z	θ_x	θ_y	θ_z
Longitudinal centerline section (half-breadth model)	–	Constraint	–	Constraint	–	Constraint
Node *G* (full-breadth model)	–	Constraint	–	–	–	–
End planes *A*, *B*	Link	Link	Link	–	–	–
Independent point *H* (end plate *A*)	Constraint	Constraint	Constraint	Constraint	Bending moment	–
Independent point *H* (end plate *B*)	–	Constraint	Constraint	Constraint	Bending moment	–

4.2.4 For boundary conditions of the model, see Figure 4.2.4.

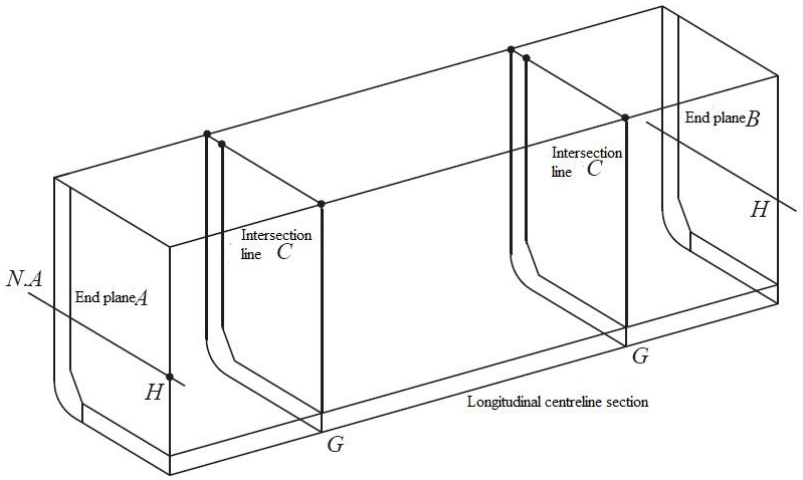

Figure 4.2.4 Boundary Conditions

5 YIELD STRENGTH EVALUATION

5.1 Allowable stresses

5.1.1 Strength evaluation is to be carried out for all primary members in the cargo tanks amidships (including bulkheads) within the longitudinal extent. The evaluation is to be based on the combined stress, which are derived from local load case and global load case in accordance with 1.5.1.9(2) of Chapter 1 of this PART.

5.1.2 The allowable stresses for primary structural members are given in Table 5.1.2.

Allowable Stresses **Table 5.1.2**

Structural member	Allowable stress（N/mm^2）	
	$[\sigma_e]$	$[\tau]$
Deck	220/ K	–
Bottom shell plating, inner bottom plating	220/ K	–
Side shell plating, inner hull plating, sloping plating of hopper tank, longitudinal bulkhead, horizontal girder in double hulls	220/ K	115/ K
Bottom girder	235/ K	115/ K
Double bottom floor	175/ K	95/ K
Transverse bulkhead	175/ K	95/ K
Side plating of lower, upper stools	195/ K	95/ K
Transverse web frame	195/ K	95/ K
Others	195/ K	–

Note: K— material factor.

6 BUCKLING STRENGTH EVALUATION

6.1 Buckling safety factors

6.1.1 The standard thickness deduction of members is given in Table 6.1.1.

Standard Thickness Deduction **Table 6.1.1**

Position		Standard thickness deduction (mm)
Within 1.5 m below weather deck	Deck and shell plating	1.0
	Inner hull and longitudinal bulkhead	2.0
	Internal structure including transverse bulkhead①	2.0
Elsewhere	Shell plating	1.0
	Inner hull and longitudinal bulkhead	1.0
	Internal structure including transverse bulkhead①	1.0

Note:
① In uncoated tanks for refined oils where an inert gas system is not fitted, the thickness deduction is to be increased by 1 mm.

6.1.2 The safety factor λ against plate panel buckling is not to be less than the minimum one in Table 6.1.2.

Minimum Buckling Safety Factor **Table 6.1.2**

Structural member	Minimum buckling safety factor
Deck	0.8
Bottom plating, inner bottom plating	0.8
Side shell plating, inner hull plating, sloping plating of hopper tank, longitudinal bulkhead	0.8
Double bottom girder, horizontal girder in double hulls	1.0
Transverse bulkhead, lower stool, upper stool	0.8
Web plating of transverse structure including midship web frame and bulkhead horizontal and vertical webs	1.0

CHAPTER 6 SINGLE HULL OIL TANKERS

Section 1 GENERAL PROVISIONS

6.1.1 Application

6.1.1.1 This Chapter applies to the structures of cargo tanks and adjacent pump rooms, ballast tanks and cofferdams (excluding bulkheads not adjacent to cargo tanks) of oil tankers with single hull and single bottom or with single hull and double bottom.

6.1.1.2 Those not covered in this Chapter are to comply with the relevant provisions in Chapter 2 and Chapter 5 of this PART.

6.1.2 Class notations

6.1.2.1 For oil tankers complying with the provisions of this Chapter, a notation of Oil Tanker, F.P. ≤ 60°C or Oil Tanker, F.P. > 60°C will be assigned.

6.1.3 Structural arrangement

6.1.3.1 Cargo tanks, double bottom, etc., are to be arranged in compliance with Section 12, Chapter 1 of this PART.

6.1.3.2 For oil tankers of 65 m or over in length, deck, bottom and inner bottom in the cargo tank region are to be longitudinally framed, while the sides may either be longitudinally framed or transversely framed. For oil tankers of less than 65 m in length, all such framing may be transverse.

6.1.4 Minimum thickness

6.1.4.1 The minimum thicknesses of structural members in cargo tank regions, pump rooms, cofferdams and other void spaces are to comply with the requirements of 5.1.6 of Section 1, Chapter 5 of this PART.

Section 2 SHELL PLATING AND DECKS

6.2.1 General requirements

6.2.1.1 The thickness of transversely framed shell plating and decks in the cargo tank region may be determined by the relevant provisions of this Section.

6.2.2 Bottom shell plating and bilge strake

6.2.2.1 The thickness t of bottom shell plating within $0.4L$ amidships is not to be less than that obtained from the following formulae:

$$t_1 = 0.072sE^{-1}(L+170)\sqrt{\frac{F_b}{K}} \quad \text{mm}$$

$$t_2 = 7.0s\sqrt{(d+h_1)F_bK} \quad \text{mm}$$

where: s — spacing of frames, in m, to be taken as not less than the standard spacing of frames;

d — draft, in m;

L — length of ship, in m;

F_b — reduction factor, see 2.2.5.6, Chapter 2 of this PART;

K — material factor;

$E = 1+\frac{s^2}{S^2}$, S being spacing of bottom girders or keels, in m;

h_1 — $0.26C$, to be taken as not greater than $0.2d$;

C — coefficient, see 2.2.3.1, Chapter 2 of this PART.

6.2.2.2 The thickness of bilge strakes is not to be less than that of bottom shell plating obtained from the calculation in 6.2.2.1 and not to be less than the actual thickness of the adjacent bottom shell plating.

6.2.3 Plate keels

6.2.3.1 The breadth of plate keels is not to be less than the requirements in 5.2.3.1, Chapter 5 of this PART, while the thickness of plate keels is not to be less than that of bottom shell plating as required in this Section plus 2 mm and not less than that of the adjacent bottom shell plating.

6.2.4 Side shell plating

6.2.4.1 The thickness t of side shell plating within 0.4L amidships is to comply with the following requirements:

(1) The thickness t of side shell plating above 3D/4 from the base line is not to be less than that obtained from the following formulae:

$$t_1 = 0.075sE^{-1}(L+110)\sqrt{\frac{F_d}{K}} \quad \text{mm}$$

$$t_2 = 4.2s\sqrt{(d+h_2)K} \quad \text{mm}$$

(2) The thickness t of side shell plating below D/4 from the baseline is not to be less than that obtained from the following formulae:

$$t_1 = 0.075sE^{-1}(L+110)\sqrt{\frac{F_b}{K}} \quad \text{mm}$$

$$t_2 = 6.3s\sqrt{(d+h_1)F_bK} \quad \text{mm}$$

where: s, d, L, h_1, K — see 6.2.2.1 of this Section;

F_b, F_d — reduction factors, see 2.2.5.6, Chapter 2 of this PART;

h_2 — 0.5C, but not to be greater than 0.36d; C being coefficient to be taken from 2.2.3.1, Chapter 2 of this PART;

E = $1+\frac{s^2}{S^2}$, S being spacing of side stringers, in m.

(3) The thickness of side shell plating above D/4 and below 3D/4 from the baseline is to be determined by interpolation from the values obtained from (1) and (2) above.

(4) For calculation of t_1, except for the minimum scope of higher tensile steels specified in Section 2 of Chapter 2, the material factor K may be taken as 1.

6.2.5 Shear strakes

6.2.5.1 The breadth of the shear strakes is not to be less than 0.1D. The thickness of the shear strake plating is not to be less than that of the adjacent side shell plating.

6.2.5.2 The thickness t of shear strakes within 0.4L amidships is not to be less than that obtained from the following formulae:

$$t_1 = 0.086sE^{-1}(L+110)\sqrt{\frac{F_d}{K}} \quad \text{mm}$$

$$t_2 = 1.05s\sqrt{(L+75)K} \quad \text{mm}$$

where: s, d, L, F_d, E, S, K — see 6.2.4.1 of this Section.

6.2.6 Strength deck plating

6.2.6.1 The thickness t of strength deck plating within 0.4L amidships is not to be less than that obtained from the following formulae:

$$t_1 = 0.086sE^{-1}(L+110)\sqrt{\frac{F_d}{K}} \quad \text{mm}$$

$$t_2 = 4.2s\sqrt{DK} \quad \text{mm}$$

where: s — spacing of transverses, in m, to be taken as not less than the standard spacing of frames;

D — moulded depth, in m;

E = $1+\frac{s^2}{S^2}$, S being spacing of deck girders, in m;

L, F_d,K— see 6.2.5.2 of this Section.

6.2.6.2 The thickness of strength deck plating is generally not to be less than that of side shear strakes obtained from the calculation in 6.2.5.2 of this Section.

Section 3 LONGITUDINAL BOTTOM FRAMING

6.3.1 General requirements

6.3.1.1 This Section applies to longitudinally framed single bottom structure.

6.3.2 Bottom longitudinals

6.3.2.1 The section modulus W of bottom longitudinals is not to be less than that obtained from the following formula:

$$W = 10sDl^2K \quad \text{cm}^3$$

where: s — spacing of longitudinals, in m;
D — moulded depth, in m;
l — span of longitudinal, in m;
K — material factor.

6.3.2.2 The connections of bottom longitudinals to bulkheads are to provide adequate fixity and continuity of longitudinal strength. Where higher tensile steels are adopted, longitudinals are to be continuous through the transverse bulkheads.

6.3.2.3 Where the bottom longitudinals are cut in way of the bulkheads, the longitudinals are to be bracketed to the bulkheads. The scantlings of the bracket are to comply with the requirements of 1.2.6, Chapter 1 of this PART, and the flange width of the bracket is not to be less than 8 times the thickness of the bracket.

Bottom longitudinals are to be welded to the web and vertical stiffeners of bottom transverses.

6.3.3 Bottom transverses

6.3.3.1 The spacing of bottom transverses is not to be greater than 3.6 m.

6.3.3.2 Where one longitudinal bulkhead is fitted in the cargo tank region at the centerline of the ship, the section modulus W and the section moment of inertia I of the bottom transverses are not to be less than those obtained from the following formulae:

$$W = 11SDl^2K \quad \text{cm}^3$$
$$I = 10.5Wl/K \quad \text{cm}^4$$

where: S — spacing of bottom transverses, in m;
D — moulded depth, in m;
l — span of bottom transverse, in m;
K — material factor.

6.3.3.3 Where the continuous centerline girder complying with 6.3.4.2 of this Section are fitted in way of centre tanks of ships having two longitudinal bulkheads within the cargo tank region, the section modulus W of the bottom transverses of the centre tanks and the net sectional area A of the associated webs at span points of the longitudinal bulkheads are not to be less than those obtained by the following formulae:

$$W = C_1SDl^2K \quad \text{cm}^3$$
$$A = C_2SDlK \quad \text{cm}^2$$

where: S — spacing of bottom transverses, in m;
D — moulded depth, in m;
l — span of bottom transverse, in m;
K — material factor.

The bending moment factor C_1 and shear factor C_2 for centerline girders and bottom transverses are based on the number of bottom transverses in the tank and factor C, as given in Table 6.3.3.3 (intermediate values are to be obtained by interpolation). The factor C is to be calculated as follows:

$$C = \frac{l_G^3 I_F}{l_F^3 I_G}$$

where: l_G — span of centerline girder, in m;
l_F — span of bottom transverse, in m;
I_G — section moment of inertia of centerline girder, in cm^4;
I_F — section moment of inertia of bottom transverse, in cm^4.

Table 6.3.3.3

C			0.02	0.06	0.10	0.20	0.30	0.40	0.50	0.60	0.70	0.80	0.90	1.00
3 bottom transverses	Girder	C_1	8.99	8.99	8.53	7.60	6.91	6.20	5.74	5.27	4.96	4.65	4.43	4.19
		C_2	0.84	0.84	0.81	0.73	0.68	0.62	0.59	0.54	0.51	0.48	0.46	0.45
	Bottom transverse	C_1	1.55	1.74	1.98	2.48	2.85	3.22	3.47	3.66	3.84	4.03	4.15	4.28
		C_2	0.31	0.33	0.35	0.39	0.42	0.45	0.47	0.49	0.50	0.51	0.52	0.53
5 bottom transverses	Girder	C_1	12.71	12.25	11.63	10.23	9.24	8.22	7.53	6.82	6.29	5.74	5.43	5.12
		C_2	1.43	1.39	1.33	1.21	1.12	1.03	0.97	0.91	0.87	0.83	0.80	0.77
	Bottom transverse	C_1	1.55	1.86	2.23	2.79	3.16	3.53	3.78	4.03	4.22	4.40	4.53	4.59
		C_2	0.32	0.34	0.37	0.41	0.44	0.47	0.49	0.51	0.53	0.54	0.55	0.56

Notes: (1) In the case of 2 bottom transverses, calculation may be performed as that for 3 bottom transverses, with C_1 being reduced by 20% and C_2 by 25% for centerline girders.
(2) In the case of 4 bottom transverses, the factor may be obtained by interpolation.

The net sectional area A of the web at mid-span of the bottom transverse is not to be less than $\left(\frac{1}{1.6C_2}-1\right)A$.

The above W and A may also be determined by direct calculation.

6.3.3.4 For ships having two longitudinal bulkheads within the cargo tank region, the scantlings (including the section modulus and the net sectional area of webs at span points) of bottom transverses of wing tanks are generally to be the same as those of bottom transverses of centre tanks.

6.3.3.5 The web depth of the bottom transverses is not to be less than 2.5 times the depth of the slot for the bottom longitudinals.

6.3.3.6 The ends of bottom transverse are to be bracketed to longitudinal bulkheads or ship side. The brackets are to comply with the requirements of 1.2.7, Chapter 1 of this PART. Where connected to ship side, the brackets are as far as possible to form a ring system.

Where the side shell and longitudinal bulkheads are framed transversely in wing cargo tanks, the raised ends of bottom transverse in the tank are to extend to the lowest side stringer and to the lowest horizontal girder of the longitudinal bulkhead. Where the side shell and longitudinal bulkheads are framed longitudinally in wing cargo tanks, the bottom transverses in the tank together with web frames, longitudinal bulkhead vertical webs and deck transverses are to form a transverse framing structure. The radius of rounded corners of the connection of the transverse framing structure to bottom transverses in the tank is generally not to be less than the web depth of adjacent members. The face plate at the connection is to be continuous and have a sectional area not less than that of the face plate of bottom transverses.

6.3.3.7 The web thickness of bottom transverses is not to be less than s/80 (s being the spacing of stiffeners). Vertical stiffeners are generally to be fitted on one side of the web plate of bottom transverses in line with the longitudinals. Where the web depth of bottom transverses exceeds $165t\sqrt{K}$ (t being the web thickness, K being material factor), an additional stiffener is to be fitted parallel to and at a distance of 1/4 web depth from the face plate.

The scantlings of vertical and horizontal stiffeners are to comply with the relevant requirements of 5.12.2.5, Chapter 5 of this PART.

6.3.3.8 Bottom transverses are generally to be fitted with tripping brackets close to the toes of end brackets and elsewhere according to the relevant requirements in 1.2.5.4, Chapter 1 of this PART.

6.3.4 Bottom centerline girder and bottom side girders

6.3.4.1 Where the length of the ship exceeds 70 m and one centerline longitudinal bulkhead is fitted, one intercostal bottom side girder is generally to be fitted at about 1/4B from the centerline on each side.

6.3.4.2 For oil tankers without the centreline longitudinal bulkhead, a continuous bottom centerline girder is to be fitted. The section modulus of the continuous centerline girder and the net sectional area A of the web at any section are not to be less than those obtained from the following formulae:

$$W = 10SDblK \quad \text{cm}^3$$
$$A = 1.45bDSK \quad \text{cm}^2$$

where: b — supporting breadth, in m, taken as half the distance between span points of the bottom transverse at both sides;
S — spacing of bottom transverses, in m;
D — moulded depth, in m;
l — span of the centerline girder, in m;
K — material factor.

6.3.4.3 The web depth of the bottom centerline girder is not to be greater than that of the bottom transverses. The web thickness of the bottom centerline girder is not to be less than that of the bottom transverses plus 2 mm.

6.3.4.4 The web thickness and face plate scantlings of the intercostal bottom side girders are to be the same as those of the bottom transverses in way, while the depth may be half of that of the bottom transverses.

6.3.5 Strengthening and end connections of bottom centreline girder

6.3.5.1 Docking brackets are to be fitted on both sides of the bottom centreline girder, midway between the bottom transverses or between the bottom transverse and the transverse bulkhead, and are to be connected to a suitable bottom longitudinal. These brackets are to have a face plate or a flange. The thickness of the brackets is to be the same as that of the web plate of the bottom centreline girder. The

bracket on one side of the centreline girder is to be extended and welded to the face plate of the centreline girder but on the other side may be terminated at a suitable horizontal stiffener.
Tripping brackets are also to be fitted close to the toes of end brackets of the continuous bottom centreline girder.
6.3.5.2 Horizontal stiffeners are to be fitted on one side of the web of the continuous centreline girder. Additional vertical stiffeners are to be suitably fitted in way of vertical webs and end brackets.
The horizontal stiffeners are to be spaced not more than $50t\sqrt{K}$ apart (t being the web thickness of the centreline girder, K being material factor), and the scantlings of the horizontal stiffeners and vertical stiffeners are to comply with the relevant requirements of 5.12.2.5, Chapter 5 of this PART.

Section 4 TRANSVERSE BOTTOM FRAMING

6.4.1 General requirements

6.4.1.1 This Section applies to transversely framed single bottom structure.

6.4.2 Bottom transverses

6.4.2.1 The solid floor is to be fitted at each bottom transverse. The web depth h, thickness t and face plate sectional area A are not to be less than those obtained from the following formulae:

$h = 42(B + d) - 70$ mm

$t = (0.01h + 3)\sqrt{K}$ mm, but need not be greater than 14 mm

$A = (4.8d - 3)K$ cm²

where: B — breadth of ship, in m;
d — draft, in m;
K — material factor.

6.4.2.2 The thickness of the face plate of bottom transverses is not to be less than the web thickness of bottom transverses, while the breadth of the face plate is not to be less than 10 times its thickness, but need not be greater than 15 times.

6.4.3 Bottom centerline girder and bottom side girders

6.4.3.1 For oil tankers without the centreline longitudinal bulkhead, a continuous bottom centerline girder is to be provided. The web thickness t and face plate sectional area A of the centerline girder throughout the cargo tank region are not to be less than those obtained from the following formulae:

$t = \sqrt{LK} + 2$ mm, and not less than 6 mm

$A = 0.67LK$ cm^2, and not less than 12.5 cm^2

where: L — length of ship, in m;
K — material factor.

6.4.3.2 The bottom centerline girder is generally to be going through the whole ship. Where terminated in way of a transverse bulkhead, the web plating of the bottom centerline girder is gradually to rise to the bulkhead within one frame space, with the raised depth being twice the original one. The face plate of the bottom centerline girder is to be extended to the bulkhead, and to have 15° scarfing as shown in Figure 6.4.3.2.

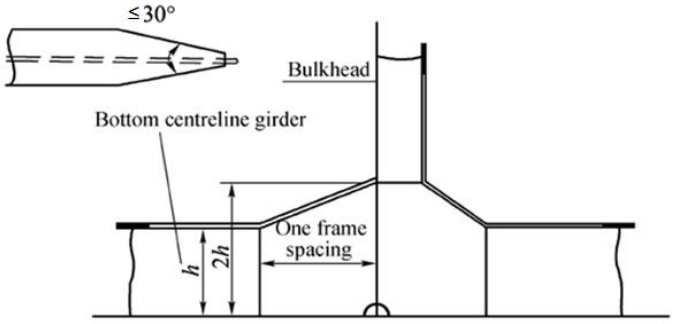

Figure 6.4.3.2

6.4.3.3 Where the breadth of the ship is equal to or less than 7 m, bottom side girders may not be provided; where the breadth is greater than 7 m but less than 12 m, at least one bottom side girder is to be provided at each side of the bottom centerline girder. Where the breadth of the ship is greater than 12 m, at

least two bottom side girders are to be provided at each side of the bottom centerline girder. The bottom side girders are to be uniformly fitted so far as practicable and extended in the fore and aft direction.

6.4.3.4 The depth of bottom side girders is to be the same as that of the bottom transverses in way. The web thickness t and the face plate area A are not to be less than those obtained from the following formulae:

$$t = \sqrt{LK} \quad \text{mm, and not less than 6 mm}$$

$$A = 0.25L + 5 \quad \text{cm}^2\text{, and not less than 10 cm}^2$$

where: L — length of ship, in m;

K — material factor.

Section 5 LONGITUDINAL SIDE FRAMING

6.5.1 Side longitudinals

6.5.1.1 The section modulus W of the side longitudinals is not to be less than that obtained from the following formula:

$$W = 8.4s\,(h + 1.2)\,l^2\,K \quad \text{cm}^3$$

where: s — spacing of longitudinals, in m;

h — vertical distance, in m, measured from the longitudinal under consideration to deck at side amidships, but not to be less than 2.5 m;

l — span of longitudinal, in m;

K — material factor.

6.5.1.2 The scantlings of bilge longitudinals are to be graduated between those required for the bottom and lowest side longitudinals.

6.5.1.3 Where longitudinal bottom and side framing is adopted, but bilge longitudinals are omitted, the spacing of transverses or equivalent bilge brackets are to comply with the requirements of 5.4.4.1, Chapter 5 of this PART.

6.5.1.4 Where the side longitudinals are cut at transverse bulkheads, these longitudinals are to be attached to the bulkheads by brackets. The arm length of the brackets are to be increased by 20% of that required in 1.2.6, Chapter 1 of this PART, and the flange width of the brackets is not to be less than 8 times their thickness.

Side longitudinals are to be welded to the web plate of side transverses.

6.5.2 Side transverses

6.5.2.1 Side transverses are to be fitted in line with each solid floor in the longitudinally framed bottom.

6.5.2.2 The section modulus W of side transverses is not to be less than that obtained from the following formula:

$$W = CS\,(h + 1.2)\,l^2\,K \quad \text{cm}^3$$

where: S — spacing of side transverses, in m;

h — vertical distance, in m, measured from the mid-span of the side transverse to deck at side;

l — span of side transverse, in m;

C — coefficient: $C = 11$, without horizontal cross ties; $C = 3.2$, with one horizontal cross tie; $C = 3$, with two horizontal cross ties;

K — material factor.

6.5.2.3 The section moment of inertia I of side transverses is not to be less than that obtained from the following formula:

$$I = 7.5Wl/K \quad \text{cm}^4$$

where: W — section modulus of side transverses, in cm^3;

l — span of side transverse, in m;

K — material factor.

6.5.2.4 Tripping brackets are generally to be fitted close to the toes of end brackets of side transverses, in way of cross ties and elsewhere in accordance with the relevant requirements of 1.2.5.4, Chapter 1 of this PART.

6.5.2.5 The web thickness of side transverses is not to be less than $s/80$ (s being the spacing of stiffeners or the depth of unstiffened web, in mm). Stiffeners normal to the face plate are generally to be fitted on one side of the web plate of side transverses in line with every side longitudinal. Where the web depth of side transverses exceeds $165t\sqrt{K}$ (t being the thickness of the web plate, K being material factor), an additional stiffener is to be fitted parallel to and at a distance of 1/4 web depth from the face plate. The scantlings of stiffeners are to comply with the requirements of 5.12.2.5, Chapter 5 of this PART.

6.5.2.6 The connection of side transverses to deck transverses and bottom transverses is to form a transverse framing structure so far as practicable. The radius of rounded corners of the connection of the transverse framing structure is generally not to be less than the web depth of adjacent members. Where independent brackets are used at upper ends of side transverses, the scantlings of the brackets are to comply with the requirements of 1.2.7, Chapter 1 of this PART.
The brackets connected to bottom transverses are to comply with the relevant requirements of 6.3.3.6 of this Chapter.

6.5.3 Cross ties

6.5.3.1 Where horizontal cross ties are to be arranged between side transverses and the vertical webs of longitudinal bulkheads, the scantlings, stiffening and end connection of the horizontal cross ties are respectively to comply with the relevant requirements of Chapter 5 of this PART.

Section 6 TRANSVERSE SIDE FRAMING

6.6.1 Side frames

6.6.1.1 The section modulus W of side frames is not to be less than that obtained from the following formula:

$$W = 11s\,(h + 1.2)\,l^2K \quad \text{cm}^3$$

where: s — spacing of side frames, in m;
h — vertical distance, in m, measured from the mid-span of the side frame to deck at side, but not to be less than 2.5 m;
l — span of side frame, in m, but not to be less than 2.5 m;
K — material factor.

Where side transverses are fitted, the section modulus of side frames may be reduced by 15% from that obtained from the above formula.
It is recommended that the section modulus of side frames fitted in line with the bottom and deck transverses be suitably increased.
6.6.1.2 The depth and breadth of the brackets connecting the side frames to deck transverses are, in general, not to be less than the depth of the web of the deck transverses.
6.6.1.3 Side frames not in line with the bottom and deck transverses are to be attached to the deck and bottom plating by brackets. The arm length of these brackets is to be 20% more than that required in 1.2.6, Chapter 1 of this PART. The brackets connected to deck are to have face plates or flanges not less than 80 mm, and are to extend to the nearest longitunudal of the deck and welded to it.
The bilge brackets are to be extended to the nearest bottom longitudinal and welded to it, covering the entire bilge. The breadth of face plates of bilge brackets is not to be less than 120 mm.
6.6.1.4 Where the lower end of side frames is lapped to the bilge brackets, the length of overlap is not to be less than twice the depth of the frames. Side frames are to be welded to the web plate of side stringers.

6.6.2 Side transverses

6.6.2.1 Where the moulded depth D exceeds 11 m, or where the spacing of oiltight or non-oiltight transverse bulkheads exceeds 15 m, side transverses complying with the requirements of 6.5.2 of this Chapter are to be fitted in line with the solid floors in the longitudinally framed bottom. Where the side transverse does not support side stringers, the section modulus of the side transverse may be reduced by 20% from that required in 6.5.2.2 of this Chapter.
For the tripping brackets fitted to the web plate of side transverses, see 6.5.2.4 of this Chapter.
For the stiffeners fitted to the web plate of side transverse, see 6.5.2.5 of this Chapter.
For brackets connecting the side transverse to deck and bottom transverses, see 6.5.2.6 of this Chapter.

6.6.3 Side stringers

6.6.3.1 Where the moulded depth is less than or equal to 7.5 m, one side stringer is to be fitted; where the moulded depth is less than 6.0 m, however, side stringers may be omitted.
Where the moulded depth is more than 7.5 m, two side stringers are generally to be fitted.
6.6.3.2 The section modulus W of side stringers is not to be less than that obtained from the following formula:

$$W = 12b\,(h + 1.2)\,l^2K \quad \text{cm}^3$$

where: b — width of supported plating, in m, to be taken as half the total length of the intersected side frame above and below the side stringer under consideration;

h — vertical distance, in m, measured from side stringer to the tank top in way of longitudinal centreline;

l — span of side stringer, in m, taken as the spacing of side transverses where side transverses are fitted;

K — material factor.

Where two or more side stringers are fitted, the section modulus of the uppermost one is to be increased by 20% above that obtained from the above formula.

6.6.3.3 The web depth of side stringers is not to be less than 2.5 times the depth of the slot for the side transverses.

6.6.3.4 Tripping brackets are generally to be fitted close to the toes of end brackets of side stringers, in way of cross ties and elsewhere in accordance with the relevant requirements of 1.2.5.4, Chapter 1 of this PART.

6.6.3.5 The web thickness of side stringers is not to be less than $s/80$ (s being the spacing of stiffeners or the depth of unstiffened web, in m). Stiffeners normal to the face plate are generally to be fitted on one side of the web plate of side stringers in line with every frame. Where the web depth of side stringers exceeds $165\,t\sqrt{K}$ (t being the thickness of the web plate, K being material factor), an additional stiffener is to be fitted parallel to and at a distance of 1/4 web depth from the face plate. The scantlings of stiffeners are to comply with the relevant requirements of 5.12.2.5, Chapter 5 of this PART.

6.6.3.6 The connection of ends of side stringers to transverse bulkheads are to comply with the following requirements: where side stringers are connected to transverse bulkhead plating, they are to gradually rise to the depth of twice the original one within the depth of about one web plate from bulkhead plating. The web plates of the stringers are to be welded to bulkhead plating. The face plates of the stringers are to extend to bulkheads. Where side stringers are connected to the horizontal girders of transverse bulkheads, they are to comply with the requirements of 1.2.7, Chapter 1 of this PART.

6.6.4 Cross ties

6.6.4.1 Where horizontal cross ties are to be arranged between side stringers and horizontal webs of longitudinal bulkheads, the scantlings, stiffening and end connection of the horizontal cross ties are respectively to comply with the relevant requirements of Chapter 5 of this PART.

Section 7 TRANSVERSE DECK FRAMING

6.7.1 Deck transverses

6.7.1.1 The section modulus W and moment of inertia I of deck transverses in the cargo tank region are not to be less than those obtained from the following formulae:

$$W = 10.8shl^2K \quad \text{cm}^3$$
$$I = 2.3Wl/K \quad \text{cm}^4$$

where: s — spacing of transverses, in m;

h — design deck head, in m, to be determined according to 2.8.1.1, Chapter 2 of this PART, but not to be less than design pressure of the breathing valves of oil tanks;

l — span of transverse, in m, but not less than 2.5 m;

K — material factor.

6.7.1.2 Deck transverses are to be bracketed to side frames. The scantlings of the brackets are to comply with the requirements of 6.6.1.3 of this Chapter. Deck transverses are to penetrate continuous deck girders, and are to be welded to them.

6.7.2 Deck girders

6.7.2.1 On strength deck, continuous deck girders are generally to be fitted longitudinally in line with bottom girders.

6.7.2.2 The section modulus W and moment of inertia I of continuous deck girders are not to be less than those obtained from the following formulae:

$$W = 12bhl^2K \text{cm}^3$$
$$I = 2.5Wl/K \ \text{cm}^4$$

where: b — mean breadth, in m, of areas supported by deck girders;

h — design deck head, in m, the same as that in 6.7.1.1 of this Section;

l — span of deck girder, in m;

K — material factor.

6.7.2.3 The web depth of deck girders is generally not to be less than 2.5 times the depth of deck transverse opening.
6.7.2.4 The connection of deck girders to transverse bulkheads or vertical webs of transverse bulkheads is to comply with the requirements of 1.2.7, Chapter 1 of this PART.
6.7.2.5 Deck girders are to be fitted with tripping brackets as specified in 1.2.5.4, Chapter 1 of this PART.

Section 8 TRUNK STRUCTURE

6.8.1 General requirements

6.8.1.1 The trunk structure is as shown in Figure 6.8.1.2. As a part of strength deck, the trunk structure is to be efficiently scarfed into the main hull structure.
6.8.1.2 Where a trunk is fitted, design moulded depth D_1 is to be measured from the baseline to equivalent deck, the position of which is to be determined from the following formulae:

$$D_1 = D + 0.6\frac{b_t h_t}{B}, \qquad \text{for}\ \frac{b_t}{B} \le 0.8$$

$$D_1 = D + h_t\left(2.6\frac{b_t}{B} - 1.6\right), \quad \text{for}\ \frac{b_t}{B} > 0.8$$

where: D, B — moulded depth and breadth of ship respectively, in m;
b_t, h_t — mean breadth and height of trunk, in m, see Figure 6.8.1.2.

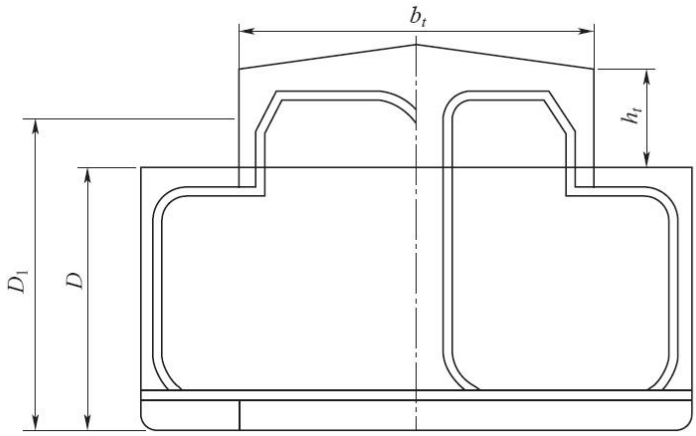

Figure 6.8.1.2

6.8.1.3 In calculation of side, deck, bottom and bulkhead scantlings where the moulded depth D is involved, it is to be replaced by the design moulded depth D_1; where the design pressure head is measured to deck at side, it is to be increased by D_1-D.

6.8.2 Structural arrangement

6.8.2.1 The trunk structure is generally to extend over the full length of the cargo tanks and effectively in the fore and aft direction. The extension length of the trunk side plating at both ends is not to be less than 1.5 times the height of the trunk, and the ends are to form radiused extension brackets which are to have a face plate or flange.
6.8.2.2 The trunk deck and sides are generally to be longitudinally framed. Transverse strength members of the trunk deck are to be arranged in line with deck transverses.
6.8.2.3 The structural arrangement at the connection of the trunk side to deck transverses is to be such as to ensure adequate rigidity and continuity of strength.
6.8.2.4 Where deck is longitudinally framed and ship side is transversely framed, web frames are to be fitted in way of deck transverses. The considered span for the determination of the scantlings of deck transverses is to be measured from the span point at side to the longitudinal bulkhead. In addition, continuous deck girders are to be provided at trunk sides. The web depth of the continuous deck girders is not to be less than that of deck transverses. The sectional area of the face plate of continuous deck girders is not to be less than that of deck transverses.
6.8.2.5 Extension brackets and strengthened vertical stiffeners or equivalent structures are to be provided at fore and aft ends of the trunk so as to ensure the continuity of strength from the trunk structure into the

main hull and superstructures. At fore and aft end bulkheads, the strength deck is to have radiused transition at corners of deck openings as required in 2.4.4, Chapter 2 of this PART.

6.8.2.6 Where strength members or longitudinal stiffeners are fitted externally to the trunk, the arrangements and scantlings of the members are to be specially considered.

6.8.3 Scantlings of members

6.8.3.1 The thickness of the trunk top and side plating as well as that of the strength deck outside the trunk sides are to comply with the requirements of Section 3, Chapter 5 of this PART.

6.8.3.2 The scantlings of trunk longitudinals and web beams are not to be less than those of the strength deck framing as required in Section 6, Chapter 5 of this PART.

6.8.3.3 The hull section modulus, at the trunk and keel, for each transverse section within 0.4*L* amidships is to comply with the relevant requirements of Section 2, Chapter 2 of this PART. All continuous longitudinal members in the trunk may be considered for the hull section modulus amidships.

CHAPTER 7 CONTAINER SHIPS

Section 1 GENERAL PROVISIONS

7.1.1 Application

7.1.1.1 This Chapter applies to ships for the carriage of standard containers in holds and on deck. Container ships engaged in unrestricted service and of 150 m and over in length are to satisfy the requirements of CCS Rules for Structures of Container Ships.

7.1.1.2 Those not covered in this Chapter are to comply with the relevant requirements of Chapter 2 of this PART.

7.1.1.3 Where the hull structural higher tensile steels of more than 50 mm and up to 100 mm in thickness with the minimum yield strength greater than 355 N/mm^2 are used on board container ships, the requirements of CCS Guidelines for Application of Thick Higher Strength Steel Plates for Ships are to be complied with.

7.1.1.4 Where the hull structural higher tensile steels with the yield strength 390 N/mm^2 are used for strength deck and coaming plating on board container ships, the material factor K may be taken as 0.66 in accordance with 1.3.1 of Section 3, Chapter 1 of this PART, provided that:

(1) the plating thickness is to be more than 50 mm;

(2) the areas of higher tensile steels with 390 N/mm^2 is to be evaluated by means of fatigue spectrum analysis, the positions under evaluation are to include the connection between hatch coamings and supporting members, and other key positions with more severe response of bending moment and torque by hull girders, in addition to those as required in 4.1.5, Appendix 2 of this Chapter;

(3) the key positions of deck and hatch coaming are to be subject to construction monitoring in accordance with the requirements of CCS Guidelines for Construction Monitoring of Hull Structures.

7.1.2 Class notation

7.1.2.1 Container ships complying with the requirements of this Chapter and fitted with the container securing arrangements complying with the requirements of Appendix 1 of this Chapter will be eligible to be assigned the class notation: Container Ship.

7.1.3 Plans and documents

7.1.3.1 In addition to the plans and documents required in Section 1, Chapter 2 of this PART, the following are to be submitted to CCS for approval:

(1) Stowage arrangement of containers;

(2) Details of reinforcement to structure in way of container corners/supports;

(3) Arrangement and structural connections of cell guides.

7.1.4 Arrangement and structural configuration

7.1.4.1 The basic structural configuration required by this Chapter includes a double bottom, and a double side skin construction with an efficient torsion box girder fitted at the topsides. Where the strength of the hull structure is ensured, a double bottom and a single side skin construction with the torsion box girder or an alternative equivalent structure may be adopted.

7.1.4.2 Longitudinal framing is to be adopted for the topside and also in the double bottom for ships over 100 m in length.

7.1.4.3 Under the hydrodynamic torque of the hull, the average torsional angle of hatch openings in the strength deck is generally not to exceed 0.006°/m and the elongation of the hatch opening diagonal is generally not to exceed 35 mm, except for open-top container ships.

7.1.5 Direct strength calculation and fatigue strength assessment for hull structure

7.1.5.1 For ships of 150 m or over in length or of the width of hatch openings in the strength deck greater than 0.85B (B being the breadth of ship), direct FE strength calculation for cargo holds is to be carried out according to the requirements of Appendix 2 of this Chapter.

For container ships of 150 m or over in length, the fatigue strength check is to be carried out for the following structural members in the cargo area in accordance with CCS Guidelines for Fatigue Strength of Ship Structure:

(1) connections of longitudinals (bottom, side, deck and inner shell) to transverse web frames;

(2) connections of longitudinals (bottom, side, deck and inner shell) to transverse bulkheads;

(3) connections of inner shell to inner bottoms.

7.1.5.2 For container ships complying with one of the following conditions, direct FE strength calculation and fatigue strength assessment for the whole ship are to be carried out according to the requirements of Appendix 2 of this Chapter:
(1) 250 m or over in length;
(2) where the breadth of ship is greater than 32.36 m;
(3) where the width of hatch openings in the strength deck greater than 0.85B (B being the breadth of ship);
(4) where the structural arrangement is of non-conventional type.

Section 2 LONGITUDINAL STRENGTH

7.2.1 General requirements

7.2.1.1 Application

(1) Application

This Section applies to the following types of ships of 90 m and over in length: container ships and ships dedicated primarily to carry their loads in containers. For container ships up to or greater than 65 m but less than 90 m in length, the requirements of longitudinal strength are referred to in Section 2 of Chapter 2 of this PART.

(2) Load limitations

The wave loads as given in 7.2.2.3 of this Section apply to ships meeting the following criteria:

Length	$90\ \text{m} \le L \le 500\ \text{m}$;
Proportion	$5 \le L/B \le 9$; $2 \le B/d \le 6$;
Block coefficient at scantling draught	$0.55 \le C_b \le 0.9$.

For ships that do not meet all of the aforementioned criteria, special considerations such as direct calculations of wave induced loads may be required by CCS.

(3) Longitudinal extent of strength assessment

The stiffness, yield strength, buckling strength and hull girder ultimate strength assessment are to be carried out in way of 0.2L to 0.75L with due consideration given to locations where there are significant changes in hull cross section, e.g. changing of framing system and the fore and aft end of the forward bridge block in case of two-island designs.

In addition, strength assessments are to be carried out outside this area. As a minimum assessments are to be carried out at forward end of the foremost cargo hold and the aft end of the aft most cargo hold.

(4) For container ships of 90 m and over in length and ships dedicated primarily to carry their loads in containers, the minimum section moduls W_0 at amidship of hull girder is to comply with the requirements of Section 2, Chapter 2 of this PART.

7.2.1.2 Symbols and definitions

(1) Symbols

L length of ship, in m, see 1.1.2 of Chapter 1;

B moulded breadth of ship, in m, see 1.1.2 of Chapter 1;

C wave parameter, see 7.2.2.3(1);

d draught, in m, see 1.1.2 of Chapter 1;

C_b block coefficient, see 1.1.2 of Chapter 1;

C_w waterplane coefficient at scantling draught d, to be taken as:

$$C_W = A_W / (LB);$$

A_w waterplane area at scantling draught d, in m^2;

R_{eH} minimum yield stress of material, in N/mm^2;

K material factor;

E Young's modulus, in N/mm^2. to be taken as $E = 2.06 \times 10^5$ N/mm^2 for steel;

M_S vertical still water bending moment in seagoing condition, in kN·m, at the cross section under consideration;

M_{Smax}, M_{Smin} permissible maximum and minimum vertical still water bending moments in seagoing condition, in kN·m, at the cross section under consideration, see 7.2.2.2(2);

M_W vertical wave induced bending moment, in kN·m, at the cross section consideration;

F_S vertical still water shear force in seagoing condition, in kN, at the cross section under consideration;

F_{Smax}, F_{Smin} permissible maximum and minimum vertical still water shearing forces in seagoing condition, in kN, at the cross section under consideration, see 7.2.2.2(2);

F_W vertical wave induced shearing force, in kN, at the cross section under consideration;

q_v shear flow along the cross section under consideration, to be calculated according to Appendix 3 of this Chapter;

$f_{NL\text{-}Hog}$ non-linear correction factor for hogging, see 7.2.2.3(2);

$f_{NL\text{-}Sag}$ non-linear correction factor for sagging, see 7.2.2.3(2);

f_R factor related to the operational profile, see 7.2.2.3(2);

t_{net} net thickness, in mm, see 7.2.1.3(1);

t_{res} reserve thickness, to be taken as 0.5 mm;

I_{net} net vertical hull girder moment of inertia at the cross section under consideration, to be determined using net scantlings as defined in 7.2.1.3, in m^4;

σ_{HG} hull girder bending stress, in N/mm^2, as defined in 7.2.2.5;

τ_{HG} hull girder shearing stress, in N/mm^2, as defined in 7.2.2.5;

X longitudinal coordinate of a location under consideration, in m;

z vertical coordinate of a location under consideration, in m;

z_n distance from the baseline to the horizontal neutral axis, in m.

(2) Fore end and aft end

The fore end (FE) of the rule length of ship (L), see Figure 7.2.1.2(1), is the perpendicular to the scantling draught waterline at the forward side of the stem.

The aft end (AE) of the rule length of ship (L), see Figure 7.2.1.2(1), is the perpendicular to the scantling draught waterline at a distance L aft of the fore end (FE).

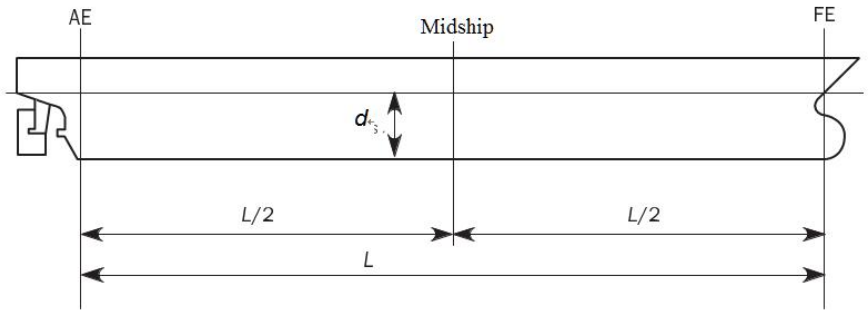

Figure 7.2.1.2(1) Ends of lenth of ship (L)

(3) Reference coordinate system

The ships geometry, loads and load effects are defined with respect to the following righthand coordinate system (see Figure 7.2.1.2(2)):

Origin: At the intersection of the longitudinal plane of symmetry of ship, the aft end of L and the baseline.

x axis: longitudinal axis, positive forwards.

y axis: transverse axis, positive towards portside.

z axis: vertical axis, positive upwards.

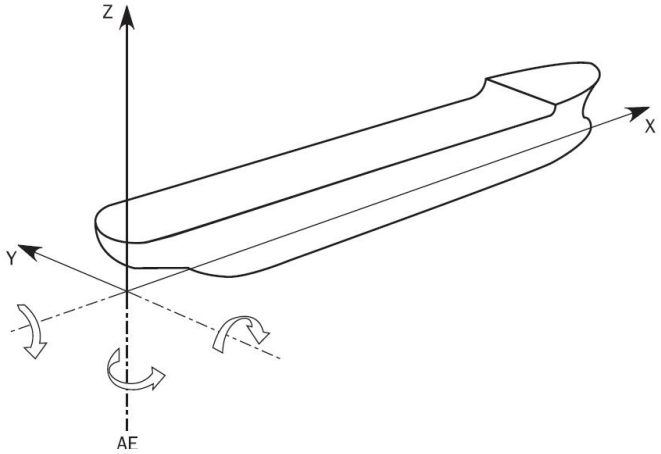

Figure 7.2.1.2(2) Reference coordinate system

7.2.1.3 Corrosion margin and net thickness

(1) Net scantling definition

The strength is to be assessed using the net thickness approach on all scantlings.
The net thickness, t_{net}, for the plates, webs and flanges is obtained by subtracting the voluntary addition t_{vol_add} and the factored corrosion addition t_c from the as built thickness t_{as_built}, as follows:

$$t_{net} = t_{as_built} - t_{vol_add} - \alpha t_c$$

where α is a corrosion addition factor whose values are defined in Table 7.2.1.3(1).
The voluntary addition, if being used, is to be clearly indicated on the drawings.

Values of corrosion addition factor **Table 7.2.1.3(1)**

Structural requirement	Property/analysis type	α
Strength assessment (7.2.3)	Section property	0.5
Buckling strength (7.2.4)	Section property (stress determination)	0.5
	Buckling capability	1.0
Hull girder ultimate strength (7.2.5)	Section property	0.5
	Buckling/collapse capacity	0.5

(2) Determination of corrosion addition
The corrosion addition for each of the two sides of a structural member, t_{c1} or t_{c2} is specified in Table 7.2.1.3(2). The total corrosion addition, t_c, in mm, for both sides of the structural member is obtained by the following formula:

$$t_c = (t_{c1} + t_{c2}) + t_{res}$$

For an internal member within a given compartment, the total corrosion addition, t_c is obtained from the following formula:

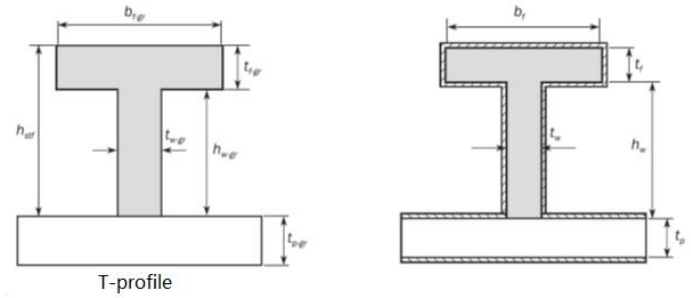
$$t_c = 2t_{c1} + t_{res}$$

The corrosion addition of a stiffener is to be determined according to the location of its connection to the attached plating.

Corrosion addition for one side of structural member **Table 7.2.1.3(2)**

Compartment type	One side corrosion addition t_{c1} or t_{c2} (mm)
Exposed to sea water	1.0
Exposed to atmosphere	1.0
Ballast water tank	1.0
Void and dry spaces	0.5
Fresh water, fuel oil and lube oil tank	0.5
Accommodation spaces	0.0
Container holds	1.0
Compartment types not mentioned above	0.5

(3) Determination of net section properties
The net section modulus, moment of inertia and shear area properties of a supporting member are to be calculated using the net dimensions of the attached plate, web and flange, as defined in Figure 7.2.1.3. The net cross-sectional area, the moment of inertia about the axis parallel to the attached plate and the associated neutral axis position are to be determined through applying a corrosion magnitude of 0.5 αt_c deducted from the surface of the profile cross-section.



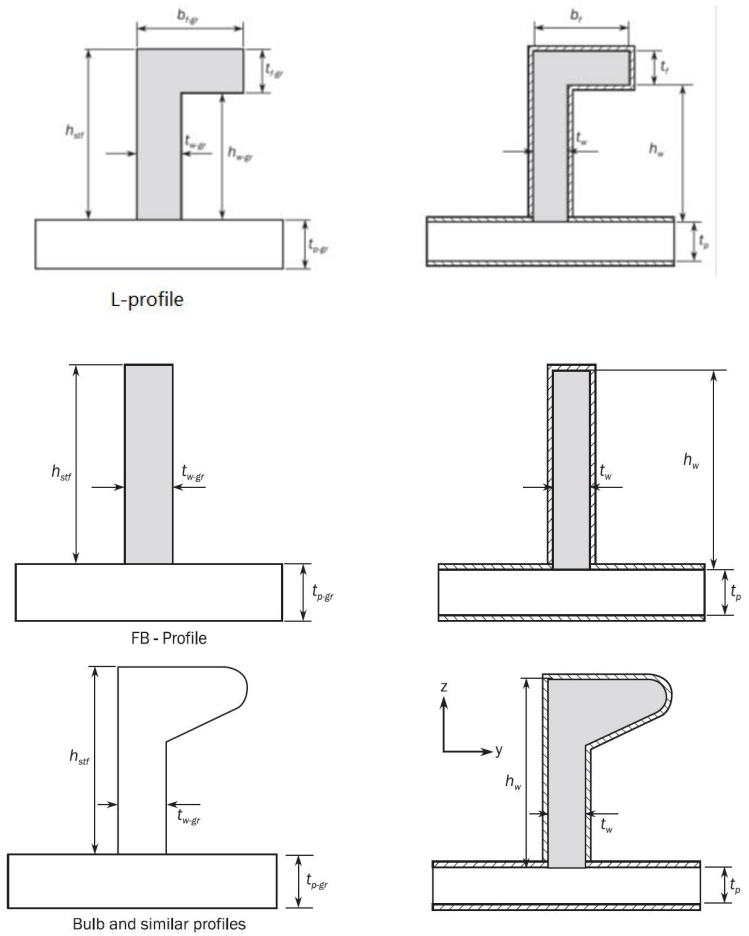


Figure 7.2.1.3 Net sectional properties of supporting members

7.2.2 Loads

7.2.2.1 Sign convention for hull girder loads

The sign conventions of vertical bending moments and vertical shear forces at any ship transverse section are as shown in Figure 7.2.2.1, namely:

- The vertical bending moments M_S and M_W are positive when they induce tensile stresses in the strength deck (hogging bending moment) and negative when they induce tensile stresses in the bottom (sagging bending moment).
- The vertical shear forces F_S, F_W are positive in the case of downward resulting forces acting aft of the transverse section and upward resulting forces acting forward of the transverse section under consideration. The shear forces in the directions opposite to above are negative.

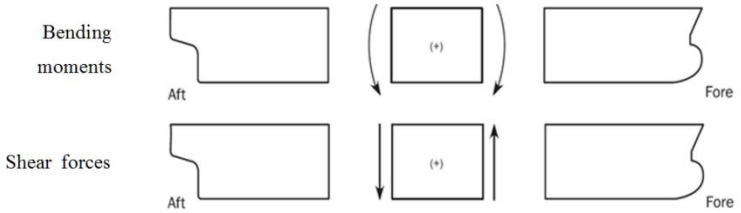

Figure 7.2.2.1 Sign conventions of bending moments and shear forces

7.2.2.2 Still water bending moments and shear forces

(1) General requirements

Still water bending moments, M_S in kN·m, and still water shear forces, F_S in kN, are to be calculated at each section along the ship length for design loading conditions as specified in 7.2.2.2(2).

(2) Design loading conditions

In general, the design cargo and ballast loading conditions, based on amount of bunker, fresh water and stores at departure and arrival, are to be considered for the M_S and F_S calculations. Where the amount and disposition of consumables at any intermediate stage of the voyage are considered more severe,

calculations for such intermediate conditions are to be submitted in addition to those for departure and arrival conditions. Also, where any ballasting and/or de-ballasting is intended during voyage, calculations of the intermediate condition just before and just after ballasting and/or de-ballasting any ballast tank are to be submitted and where approved included in the loading manual for guidance.

The permissible vertical still water bending moments M_{Smax} and M_{Smin} and the permissible vertical still water shear forces F_{Smax} and F_{Smin} in seagoing conditions at any longitudinal position are to envelop:

- the maximum and minimum still water bending moments and shear forces for the seagoing loading conditions defined in the Loading Manual;
- the maximum and minimum still water bending moments and shear forces specified by the designer.

The Loading Manual is to include the relevant loading conditions, which envelop the still water hull girder loads for seagoing conditions, including those specified in 2.2.2.3 of Section 2, Chapter 2 of this PART.

7.2.2.3 Wave loads

(1) Wave parameter

The wave parameter is defined as follows:

$$C = 1 - 1.50\left(1 - \sqrt{\frac{L}{L_{ref}}}\right)^{2.2}, \text{ for } L \le L_{ref}$$

$$C = 1 - 0.45\left(\sqrt{\frac{L}{L_{ref}}} - 1\right)^{1.7}, \text{ for } L > L_{ref}$$

where: L_{ref} — reference length of ship, in m, taken as:

$L_{ref} = 315C_W^{-1.3}$ for the determination of vertical wave bending moments according to 7.2.2.3(2);

$L_{ref} = 330C_W^{-1.3}$ for the determination of vertical wave shear forces according to 7.2.2.3(3).

(2) Vertical wave bending moments

The distribution of the vertical wave induced bending moments, M_W in kN·m, along the ship length is given in Figure 7.2.2.3(2), where:

$$M_{W-Hog} = +1.5 f_R L^3 C C_W \left(\frac{B}{L}\right)^{0.8} f_{NL-Hog}$$

$$M_{W-Sag} = -1.5 f_R L^3 C C_W \left(\frac{B}{L}\right)^{0.8} f_{NL-Sag}$$

where: f_R —factor related to the operational profile, to be taken as:

$f_R = 0.85$;

$f_{NL\text{-}Hog}$ — non-linear corrosion for hogging, to be taken as:

$f_{NL-Hog} = 0.3\dfrac{C_B}{C_W}\sqrt{d}$, and not more than 1.1;

$f_{NL\text{-}Sag}$ — non-linear corrosion for sagging, to be taken as:

$f_{NL-Sag} = 4.5\dfrac{1 + 0.2 f_{Bow}}{C_W\sqrt{C_B}L^{0.3}}$, and not less than 1.0;

f_{Bow} —bow flare shape coefficient, to be taken as:

$f_{Bow} = \dfrac{A_{DK} - A_{WL}}{0.2Lz_f}$;

A_{DK} — projected area in horizontal plane of uppermost deck, in m^2, including the forecastle deck, if any, extending from 0.8L forward (see Figure 7.2.2.3(1)). Any other structures, e.g. plated bulwark, are to be excluded;

A_{WL} —waterplane area, in m^2, at draught T, extending from 0.8L forward;

z_f — vertical distance, in m, from the waterline at draught d to the uppermost deck (or forecastle deck), measured at FE (see Figure 7.2.2.3(1)). Any other structures, e.g. plated bulwark, are to be excluded.

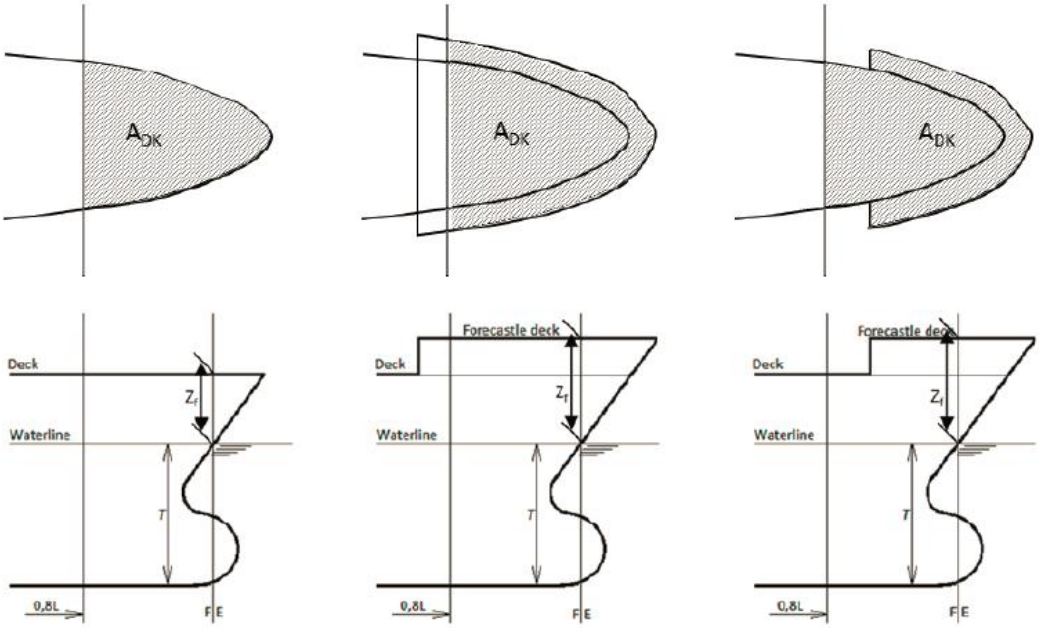

Figure 7.2.2.3(1) Projected area A_{DK} and vertical distance z_f

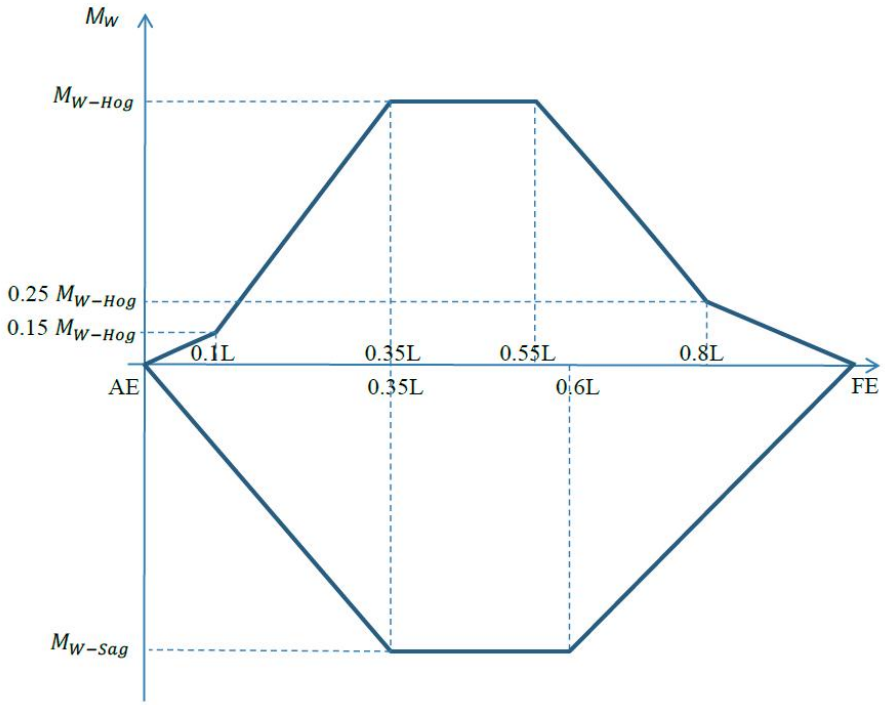

Figure 7.2.2.3(2) Distribution of vertical wave bending moment M_W along the ship length

(3) Vertical wave shear force

The distribution of the vertical wave induced shear forces, F_W in kN, along the ship length is given in Figure 7.2.2.3(3), where,

$$Fw_{Hog}^{Aft} = +5.2 f_R L^2 C C_W \left(\frac{B}{L}\right)^{0.8} \left(0.3 + 0.7 f_{NL-Hog}\right)$$

$$Fw_{Hog}^{Fore} = -5.7 f_R L^2 C C_W \left(\frac{B}{L}\right)^{0.8} f_{NL-Hog}$$

$$Fw_{Sag}^{Aft} = -5.2 f_R L^2 C C_W \left(\frac{B}{L}\right)^{0.8} \left(0.3 + 0.7 f_{NL-Sag}\right)$$

$$Fw_{Sag}^{Fore} = +5.7 f_R L^2 C C_W \left(\frac{B}{L}\right)^{0.8} \left(0.25 + 0.75 f_{NL-Sag}\right)$$

$$Fw^{Mid} = +4.0 f_R L^2 C C_W \left(\frac{B}{L}\right)^{0.8}$$

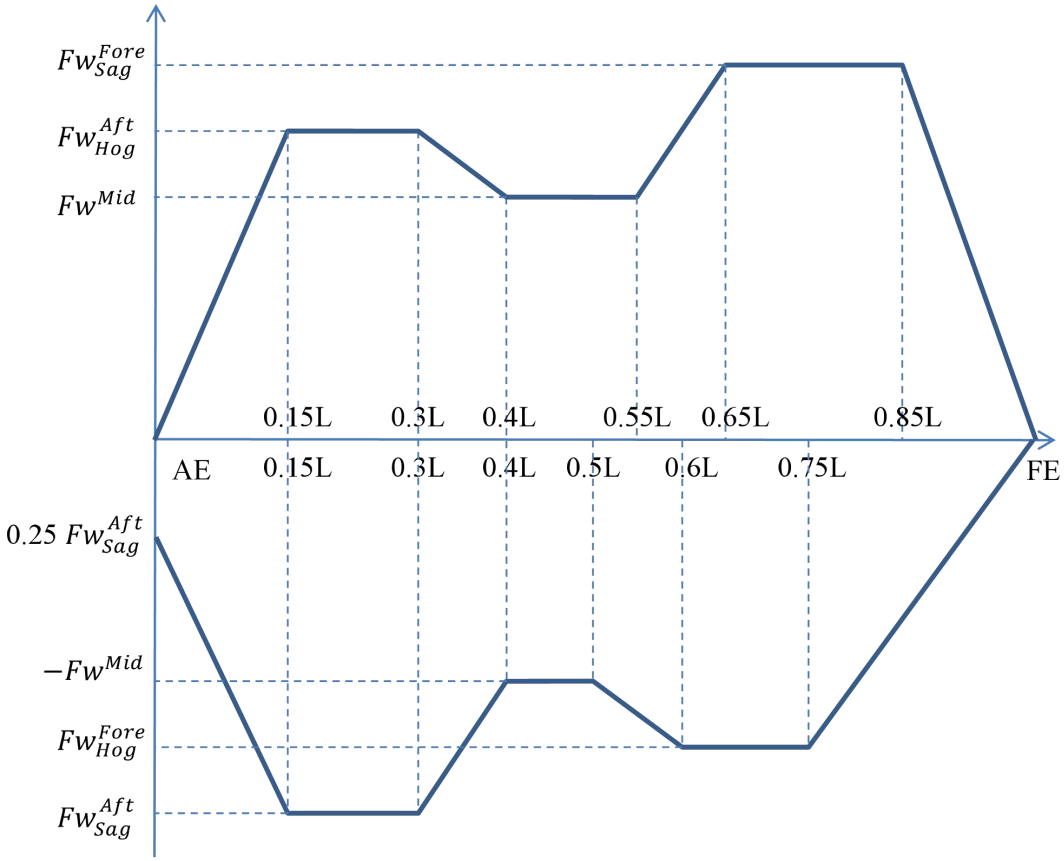

Figure 7.2.2.3(3) Distribution of vertical wave shear force FW along the ship length

7.2.2.4 Load cases

For the strength assessment, the maximum hogging and sagging load cases given in Table 7.2.2.4 are to be checked. For each load case the still water condition at each section as defined in 7.2.2.2 is to be combined with the wave condition as defined in 7.2.2.3, refer also to Figure 7.2.2.4.

Combination of still water and wave bending moments and shear forces Table 7.2.2.4

Load case	Bending moment		Shear force	
	M_S	M_W	F_S	F_W
Hogging	M_{Smax}	M_{WH}	F_{Smax} for $x \leq 0.5L$	F_{Wmax} for $x \leq 0.5L$
			F_{Smin} for $x > 0.5L$	F_{Wmin} for $x > 0.5L$
Sagging	M_{Smin}	M_{WS}	F_{Smin} for $x \leq 0.5L$	F_{Wmin} for $x \leq 0.5L$
			F_{Smax} for $x > 0.5L$	F_{Wmax} for $x > 0.5L$

M_{WH}: Wave bending moment in hogging at the cross section under consideration, to be taken as the positive value of M_W as defined in Figure 7.2.2.3(2).

M_{WS}: Wave bending moment in sagging at the cross section under consideration, to be taken as the negative value of M_W as defined Figure 7.2.2.3(2).

F_{Wmax}: Maximum value of the wave shear force at the cross section under consideration, to be taken as the positive value of F_W as defined Figure 7.2.2.3(3).

F_{Wmin}: Minimum value of the wave shear force at the cross section under consideration, to be taken as the negative value of F_W as defined Figure 7.2.2.3(3).

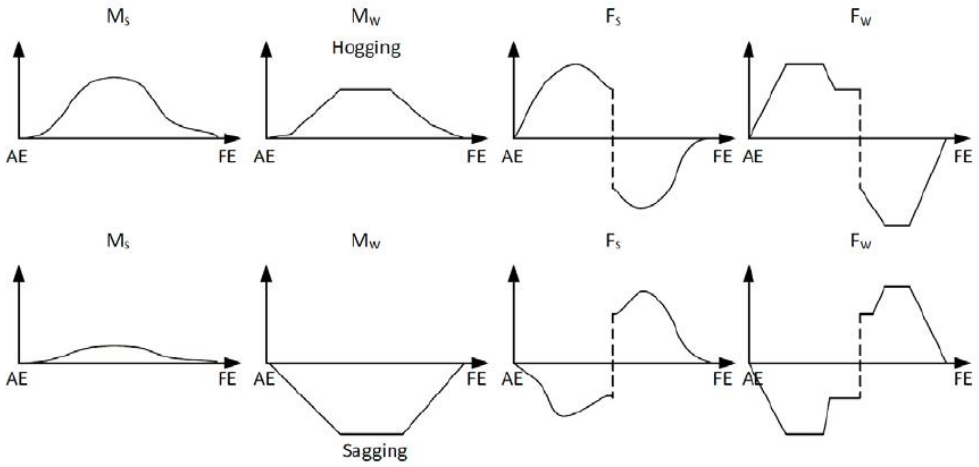

Figure 7.2.2.4 Load combination to determine the maximum hogging and sagging load cases as given in Table 7.2.2.4

7.2.2.5 Hull girder stress

The hull girder stresses, in N/mm^2, are to be determined at the load calculation point under consideration, for the "hogging" and "sagging" load cases defined in 7.2.2.4 as follows:

Bending stress:

$$\sigma_{HG} = \frac{\gamma_S M_S + \gamma_W M_W}{I_{net}}(z - z_n)10^{-3}$$

Shear stress:

$$\tau_{HG} = \frac{\gamma_S F_S + \gamma_W F_W}{t_{net} / q_v}10^3$$

where: γ_S, γ_W — partial safety factor, to be taken as:

$\gamma_S = 1.0$

$\gamma_W = 1.0$

7.2.3 Strength assessment

7.2.3.1 General requirements

Continuity of structure is to be maintained throughout the length of the ship. Where significant changes in structural arrangement occur adequate transitional structure is to be provided.

7.2.3.2 Stiffness criterion

The two load cases "hogging" and "sagging" as listed in 7.2.2.4 are to be checked.

The net moment of inertia, I_{net}, in m^4, is not to be less than:

$$I_{net} \geq 1.55L\left|M_S + M_W\right|10^{-7}$$

7.2.3.3 Yield strength assessment

(1) General acceptance criteria

The yield strength assessment is to check, for each of the load cases "hogging" and "sagging" as defined in 7.2.2.4, that the equivalent hull girder stress σ_{eq}, in N/mm^2, is less than the permissible stress σ_{perm}, in N/mm^2, as follows:

$$\sigma_{eq} < \sigma_{perm}$$

where: $\sigma_{eq} = \sqrt{\sigma_x^2 + 3\tau^2}$

$$\sigma_{perm} = \frac{R_{eH}}{\gamma_1 \gamma_2}$$

γ_1 — partial safety factor for material, to be taken as $\gamma_1 = K\frac{R_{eH}}{235}$;

γ_2 — partial safety factor for load combinations and permissible stress, to be taken as:

- $\gamma_2 = 1.24$, for bending strength assessment according to 7.2.3.3(2);
- $\gamma_2 = 1.13$, for shear stress assessment according to 7.2.3.3(3).

(2) Bending strength assessment

The assessment of the bending stresses is to be carried out according to 7.2.3.3(1) at the following locations of the cross section:

- at bottom;
- at deck;
- at top of hatch coaming;
- at any point where there is a change of steel yield strength.

The following combination of hull girder stress as defined in 7.2.2.5 is to be considered:

$$\sigma_x = \sigma_{HG}$$

$$\tau = 0$$

(3) Shear strength assessment

The assessment of shear stress is to be carried out according to 7.2.3.3(1) for all structural elements that contribute to the shear strength capability①.

The following combination of hull girder stress as defined in 7.2.2.5 is to be considered:

$$\sigma_x = 0$$

$$\tau = \tau_{HG}$$

7.2.4 Buckling strength

7.2.4.1 Application

These requirements apply to plate panels and longitudinal stiffeners subject to hull girder positive bending and shear stresses. For the positive stress acted on plate panels and longitudinal stiffeners induced by hull girder bending, the buckling strength is to be taken into account only when the positive stress is the compression stress.

Definitions of symbols are given in Appendix 4 “Buckling Capacity”.

7.2.4.2 Buckling criteria

The acceptance criterion for the buckling assessment is defined as follows:

$$\eta_{act} \le 1$$

where: η_{act} — maximum utilisation factor as defined in 7.2.4.3.

7.2.4.3 Buckling utilisation factor

The utilisation factor, η_{act} , is defined as the inverse of the stress multiplication factor at failure γ_c, see Figure 7.2.4.3.

$$\eta_{act} = \frac{1}{\gamma_c}$$

Failure limit states are defined in:

- Appendix 4 of this Chapter, 2 for elementary plate panels;
- Appendix 4 of this Chapter, 3 for overall stiffened panels;
- Appendix 4 of this Chapter, 4 for longitudinal stiffeners.

Each failure limit state is defined by an equation, and γ_c is to be determined such that it satisfies the equation.

Figure 7.2.4.3 illustrates how the stress multiplication factor at failure γ_c , of a structural member is determined for any combination of longitudinal and shear stress, where:

σ_x, τ — applied stress combination for buckling given in 7.2.4.4(1);

σ_c, τ_c— critical buckling stresses to be obtained according to Appendix 4 of this Chapter for the stress combination for buckling σ_x and τ.

① Where the shear strength is checked beyond the range of 0.2L to 0.75L, the permissible stress is generally to be in accordance with 7.2.3.3(1).

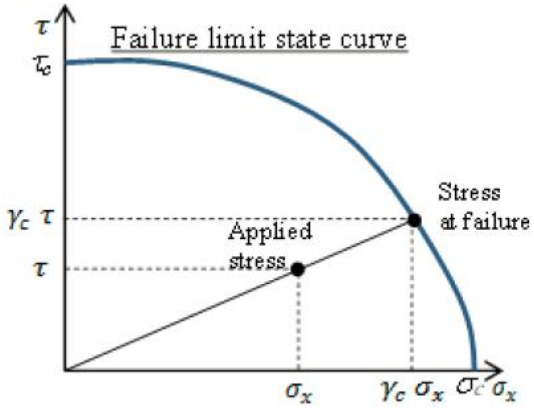

Figure 7.2.4.3 Example of failure limit state curve and stress multiplication factor at failure

7.2.4.4 Stress determination

(1) Stress combinations for buckling assessment

The following two stress combinations are to be considered for each of the load cases "hogging" and "sagging" as defined in 7.2.2.4. The stresses are to be derived at the load calculation points defined in 7.2.4.4(2).

(a) Longitudinal stiffening arrangement:

Stress combination 1 with:

$$\sigma_x = -\sigma_{HG}$$

$$\sigma_y = 0$$

$$\tau = 0.7\tau_{HG}$$

Stress combination 2 with:

$$\sigma_x = -0.7\sigma_{HG}$$

$$\sigma_y = 0$$

$$\tau = \tau_{HG}$$

(b) Transverse stiffening arrangement:

Stress combination 1 with:

$$\sigma_x = 0$$

$$\sigma_y = -\sigma_{HG}$$

$$\tau = 0.7\tau_{HG}$$

Stress combination 2 with:

$$\sigma_x = 0$$

$$\sigma_y = -0.7\sigma_{HG}$$

$$\tau = \tau_{HG}$$

(2) Load calculation points

The hull girder stresses for elementary plate panels (EPP) are to be calculated at the load calculation points defined in Table 7.2.4.4.

Load calculation points (LCP) coordinates for plate buckling assessment

Table 7.2.4.4

LCP coordinates	Hull girder bending stress		Hull girder shear stress
	Non horizontal plating	Horizontal plating	
x ordinate	Middle length of the EPP		
y coordinate	Both upper and lower ends of EPP (points A1 and A2 in Figure 7.2.4.4)	Outboard and inboard ends of EPP (points A1 and A2 in Figure 7.2.4.4)	Middle point of EPP (point B in Figure 7.2.4.4)
z coordinate	Corresponding to *x* and *y* values		

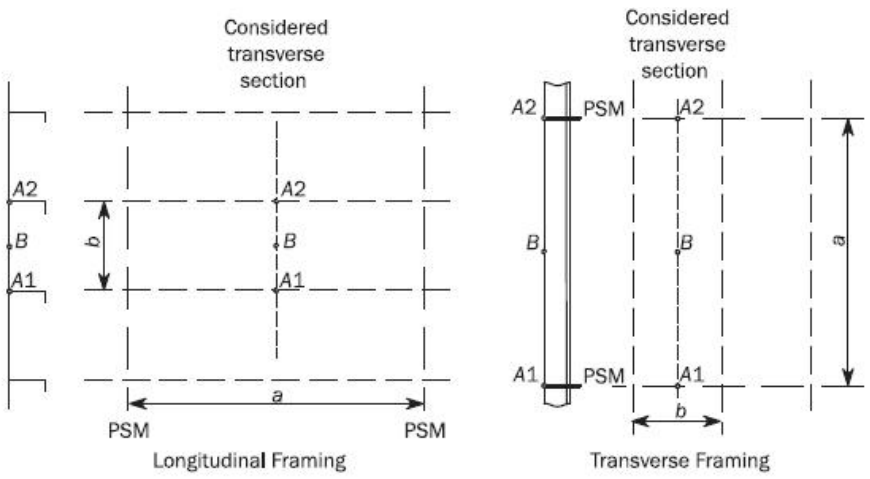

Figure 7.2.4.4 LCP for plate buckling assessment (PSM stands for primary supporting members)

The hull girder stresses for longitudinal stiffeners are to be calculated at the following load calculation point:

- at the mid length of the considered stiffener;
- at the intersection point between the stiffener and its attached plate.

7.2.5 Hull girder ultimate strength

7.2.5.1 General requirements

The hull girder ultimate strength is to be assessed for ships with length L equal to or greater than 150 m.

The acceptance criteria, given in 7.2.5.4 are applicable to intact ship structures.

The hull girder ultimate bending capacity is to be checked for the load cases "hogging" and "sagging" as defined in 7.2.2.4.

7.2.5.2 Hull girder ultimate bending moments

The vertical hull girder bending moment, M in hogging and sagging conditions, to be considered in the ultimate strength check is to be taken as:

$$M = \gamma_S M_S + \gamma_W M_W$$

where: M_s — permissible still water bending moment, in kN·m, defined in 7.2.2.2;

M_w — vertical wave bending moment, in kN·m, defined in 7.2.2.3;

γ_S — partial safety factor for the still water bending moment, to be taken as: γ_S = 1.0;

γ_W — partial safety factor for the vertical wave bending moment, to be taken as:

γ_W = 1.2.

7.2.5.3 Hull girder ultimate bending capacity

(1) General requirements

The hull girder ultimate bending moment capacity, M_U is defined as the maximum bending moment capacity of the hull girder beyond which the hull structure collapses.

(2) Determination of hull girder ultimate bending moment capacity

The ultimate bending moment capacities of a hull girder transverse section, in hogging and sagging conditions, are defined as the maximum values of the curve of bending moment M versus the curvature χ of the transverse section considered (M_{UH} for hogging condition and M_{US} for sagging condition, see Figure 7.2.5.3). The curvature χ is positive for hogging condition and negative for sagging condition.

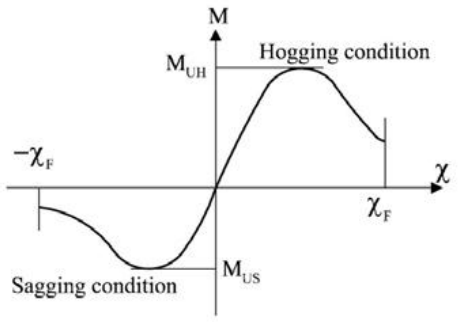

Figure 7.2.5.3 Bending moment M versus curvature χ

The hull girder ultimate bending moment capacity M_U is to be calculated using the incremental-iterative method as given in Appendix 5 of this Chapter or using an alternative method as indicated in Appendix 5.

7.2.5.4 Acceptance criteria

The hull girder ultimate bending capacity at any hull transverse section is to satisfy the following criteria:

$$M \leq \frac{M_U}{\gamma_M \gamma_{DB}}$$

where: M — vertical bending moment, in kN·m, to be obtained as specified in 7.2.5.2

M_U — hull girder ultimate bending capacity, in kN·m, to be obtained as specified in 7.2.5.3;

γ_M — partial safety factor for the hull girder ultimate bending capacity, covering material, geometric and strength prediction uncertainties, to be taken as: γ_M =1.05;

γ_{DB} — partial safety factor for the hull girder ultimate bending moment capacity, covering the effect of double bottom bending, to be taken as:

- for hogging condition: γ_{DB} = 1.15;
- for sagging condition: γ_{DB} = 1.0.

For cross sections where the double bottom breadth of the inner bottom is less than that at amidships or where the double bottom structure differs from that at amidships (e.g. engine room sections), the factor γ_{DB} for hogging condition may be reduced based upon agreement with CCS.

7.2.6 Additional requirements for large container ships

7.2.6.1 General requirements

The requirements of 7.2.6.2 and 7.2.6.3 are applicable, in addition to requirements of 7.2.3 to 7.2.5, to container ships with a breadth B greater than 32.26 m.

7.2.6.2 Yielding and buckling assessment

Yielding and buckling assessments are to be carried out taking into consideration additional hull girder loads (wave torsion, wave horizontal bending and static cargo torque), as well as local loads. All in-plane stress components (i.e. bi-axial and shear stresses) induced by hull girder loads and local loads are to be considered. See 3 of appendix 2 to this Chapter for detailed analysis methods.

7.2.6.3 Whipping

Hull girder ultimate strength assessment is to take into consideration the whipping contribution to the vertical bending moment. For detailed methods, see CCS Guidelines for Direct Calculation Assessment of Hull Structure Including Springing and Whipping.

Section 3 DECK STRUCTURE

7.3.1 General requirements

7.3.1.1 In addition to the requirements of Sections 4 and 8, Chapter 2 of this PART, the scantlings of the deck structure are to comply with the requirements for the longitudinal strength in Section 2 of Chapter 2 of this PART and Section 2 of this Chapter.

7.3.1.2 The strength deck throughout the region of container holds is to be longitudinally framed and the scantlings of the structural members of the strength deck determined in accordance with the hull section modulus required in Section 2 of Chapter 2 of this PART and Section 2 of this Chapter are to be kept unchanged over the region of container holds.

7.3.1.3 In order to ensure the hull structural strength, particular attention is to be paid to continuity of the deck structure and abrupt changes of shape, section or plate thickness are to be avoided. Effective transition arrangements are to be fitted at both end structures of the deck opening length. Arrangement in way of hatch corners and openings are to be such as to minimize the creation of stress concentrations.

7.3.1.4 Where the difference between the thicknesses of plating inside and outside the line of strength deck openings exceeds 12 mm, a transition plate with a thickness equal to the mean of the adjacent plate thicknesses is to be fitted.

7.3.1.5 Where the lower deck acts as a primary support for the side framing, the deck plating thickness may be required to be suitably increased.

7.3.2 Cross deck strips

7.3.2.1 Where the cross deck strips of the strength deck form the top of a transverse bulkhead, their breadth b is not to be less than that obtained from the following formula:

$$b = 1000 + 1.5L \quad \text{mm}$$

where: L — length of ship, in m.

7.3.2.2 Where a transverse bulkhead top box is fitted, a reduced width of cross deck strips of the strength deck may be considered by calculation as appropriate.

7.3.2.3 In addition to complying with the requirement of 2.4.2.2, Chapter 2 of this PART, the thickness t of cross deck strips of the strength deck is not to be less than that obtained from the following formula:

$$t = 10 + 0.01L \quad \text{mm}$$

where: L — length of ship, in m.

7.3.2.4 The thickness t of cross deck strips of the second tier deck below the strength deck is not to be less than that obtained from the following formula, but not less than 8 mm:

$$t = 12s \quad \text{mm}$$

where: s — spacing of beams, in m, to be taken as not less than the standard spacing of beams.

7.3.2.5 The thickness of cross deck strips of other decks below the second tier deck may be 8 mm.

7.3.2.6 The cross deck strips are to be sufficiently stiffened in the transverse direction, and the thickness of the strips is to be increased locally in way of stress concentration.

7.3.2.7 The ends of cross deck strips are to be effectively connected to the torsion box structures.

7.3.3 Strength deck girders

7.3.3.1 Girders supporting the longitudinal coaming plating are to be fitted under the strength deck (except where torsion box structures are fitted).

7.3.3.2 The strength deck girders are to be continuous throughout the container hold area, including the engine room where this is situated between container holds.

7.3.3.3 The ends of strength deck girders are to be integrated into the structures outside the container hold area. Special consideration is to be given to the connection of the girders with the transverse box girders.

7.3.4 Deck openings

7.3.4.1 The corners of hatchway openings in the strength deck are to be rounded. The radius of hatch corners near the ship's sides is not to be less than $0.35 + 0.0005L$ m (L being the length of ship, in m), and the radius of hatch corners in way of the intersection of deck girders with cross deck strips is not to be less than 0.25 m. For rounded corners with negative radii, the designer is to provide technical reasons.

7.3.4.2 The radius of the hatch corners of the cargo hatchway openings adjacent to the engine room is to be made as large as practicable, with a radius of approximately $0.04B$ mm (B being the breadth of ship, in m).

7.3.4.3 Insert plates are required at the hatch corners and to have a thickness increased by 15% above that of the strength deck plating. For container holds adjacent to the engine room, such insert plates are to be increased in thickness by 25% above that of the strength deck plating but not less by 4 mm and not more than 7 mm, and they are to be made of the same material as the strength deck. If the thickness of the insert plate can not meet above requirements, direct calculation method covering yield, buckling and fatigue is to be adopted for verification. The extension of the insert plates is to comply with Figure 7.3.4.3 (R is the radius of hatch corner, e is not to be less than 760 mm and for longitudinal framing, not to be less than one longitudinal spacing).

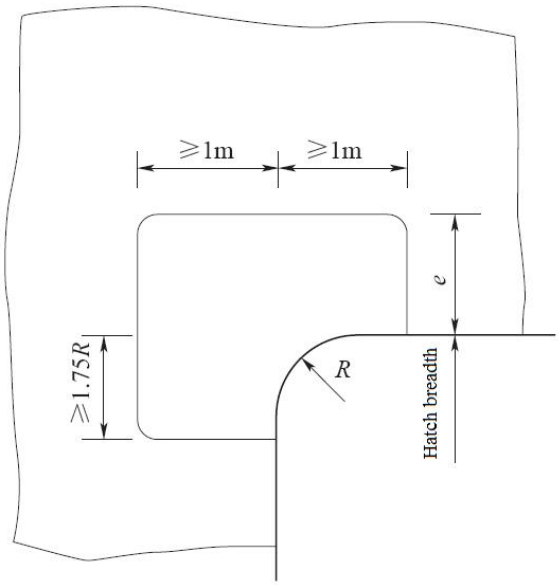

Figure 7.3.4.3

7.3.4.4 Openings are generally not to be arranged in the strength deck outside the line of hatch openings in the region of container holds.

7.3.5 Hatch coamings

7.3.5.1 Where the hatch coaming is to be continuous over the entire opening area, the ends of the coaming are to have an appropriate structural transition.

7.3.5.2 The structure of hatch coamings is to comply with the relevant requirements in Section 20 of Chapter 2 of this PART.

Section 4 SHELL PLATING

7.4.1 Bottom plating and bilge strakes

7.4.1.1 In addition to the requirements of Section 3 of Chapter 2 of this PART, the thickness of bottom plating is to comply with the requirements for longitudinal strength in Section 2 of Chapter 2 of this PART and Section 2 of this Chapter.

7.4.1.2 For transversely framed bottom plating and bilge strakes, special attention is to be paid to their buckling strength.

7.4.2 Sheer strake and side shell plating

7.4.2.1 In addition to the relevant requirements of Section 3 of Chapter 2 of this PART, the thickness of sheer strake and side shell plating is to comply with the requirements for longitudinal strength in Section 2 of Chapter 2 of this PART and Section 2 of this Chapter. At positions where high forces are present and at positions of the side shell plating where the double side skin structures terminate, local increases in thickness may be required.

7.4.2.2 The difference in thickness between the sheer strake and the shell plating below is not to exceed 1/2 of the thickness of sheer strake.

Section 5 SIDE FRAMING

7.5.1 Single side skin framing

7.5.1.1 The arrangement and the scantlings of side framing are to comply with the requirements of Section 7, Chapter 2 of this PART. CCS may require that direct calculation be carried out for checking the strength of the primary supporting members.

7.5.1.2 Where longitudinal side framing is adopted, the web frames are to be arranged in line with the solid floors in the double bottom and the transverse frames in the torsion box to form a ring system so as to ensure the transverse strength of the ship.

7.5.2 Double side skin framing

7.5.2.1 The minimum plate thickness t of transverse frames and horizontal flats (including perforated flats) within the double side skin construction is not to be less than that obtained from the following formula, but need not be greater than 9 mm:

$$t = 7.5 + 0.015L \quad \text{mm}$$

where: L — length of ship, in m.

7.5.2.2 Transverse frames and horizontal flats are to be fitted with stiffening members and their thickness is to be increased locally where high shear forces are present.

Section 6 DOUBLE BOTTOM

7.6.1 General requirements

7.6.1.1 Unless otherwise stated by this Section, the scantlings of structural members of double bottom are to comply with the relevant provisions of Section 6, Chapter 2 of this PART, but local stiffening is to be required under container corner seatings. Where the double bottom is interconnected with side tanks or deep cofferdams, the watertight floors and watertight girders are to comply with the requirements for deep tanks in Section 13 of Chapter 2 of this PART.

7.6.1.2 The requirements of 2.6.9.2(2), Section 6, Chapter 2 of this PART do not apply to the cargo holds carrying containers only.

7.6.1.3 For container ships of 150 m and over in length, the double bottom structure may comply with the requirements of 7.9.10 of this Chapter, except 7.9.10.12.

7.6.2 Girders and floors

7.6.2.1 Side girders are to be arranged under container corner seatings.

7.6.2.2 Vertical or horizontal stiffeners are to be fitted for girders in region of container holds, the height of stiffener is normally not less than 150 mm. When the length of ship is less than 150 m, the height of stiffener is not to be less than L (mm) but not less than 50 mm.

7.6.2.3 For double bottoms longitudinally framed, solid floors are to be fitted under transverse bulkheads and below mid-hold or quarter-length-of-hold supporting structures.

7.6.2.4 The thickness of solid floors in region of container holds is to comply with the following requirements:

(1) The thickness t of solid floor is not to be less than the value obtained from the following formula, but need not be greater than 12 mm:

$$t = 0.6\sqrt{LK} + 2.5 \quad \text{mm}$$

where: L — length of ship;

K— material factor.

(2) In addition to complying with the requirements of (1) of this paragraph, the thickness t of watertight floors is not to be less than that obtained from the following formula:

$$t = 0.02L\sqrt{K} + 7 \quad \text{mm}$$

where: L and K are defined in (1) of this paragraph.

7.6.2.5 For longitudinally framed containership, the thickness t of the centre girders in region of container holds is not to be less than:

$$t = f_{db}\left(0.0077h_0 + 4\right)\sqrt{K} \quad \text{mm}$$

The thickness t of side girder in region of container holds is not to be less than the value obtained from the following formula:

$$t = f_{db}\left(0.0077h_0 + 1\right)\sqrt{K} \quad \text{mm}$$

where: f_{db} —correction factor of height of double bottom;

$f_{db} = 1$ when L<150m;

$f_{db} = h_0/h_a$ when $L \geq$150m, but not to be less than 0.9; Where the longitudinal girder complies with the requirements for direct calculation of global strength of ship in Appendix 2, $f_{db} = h_0/h_a$ but not to be less than 0.85.

h_0 — considered height of double bottom, in mm, see Section 6 of Chapter 2;

h_a — actual height of double bottom, in mm;

K — material factor.

7.6.2.6 Where container holds are fitted between engine room and aft peak tank, the primary members at bottom are to comply with relevant requirements in Section 6, Chapter 2 of this PART.
7.6.2.7 For double bottom framed longitudinally and fitted with center girders, brackets leading to adjacent longitudinals are to be fitted respectively at both sides of the center girder between the solid floors.
7.6.2.8 Where torsion box center girder is used for double bottom framed longitudinally, the arrangement and the section modulus of web frame ring are to comply with relevant requirements of 7.9.10.6 of Section 9 of this Chapter.

7.6.3 Supporting structure of double bottom

7.6.3.1 Where mid-hold or quarter-length-of-hold supports for the double bottom structure are arranged, these are to take the form of an efficiently stiffened transverse box or other equivalent structures.

Section 7 BULKHEADS

7.7.1 Inner skin longitudinal bulkheads

7.7.1.1 In addition to the relevant requirements of Sections 12 and 13 of Chapter 2 of this PART, the scantlings of inner skin longitudinal bulkheads are to comply with the requirements for longitudinal strength in Section 2 of Chapter 2 of this PART and Section 2 of this Chapter.
7.7.1.2 The longitudinal members of inner skin longitudinal bulkheads are to be continuous throughout the container hold area and maintained continuous in way of the machinery space where this is situated between container holds.
7.7.1.3 Where the inner skin bulkheads are stepped, the scarfing arrangements in way of the steps are to be sufficient to ensure an efficient overlap having a length of not less than 3 frame spacings for transition.
7.7.1.4 Adequate transition arrangements are to be fitted at both ends of the inner skin longitudinal bulkhead.
7.7.1.5 The difference in thickness between the top strake and the bulkhead plating below (at the torsion box) is not to exceed 25 mm.

7.7.2 Watertight transverse bulkheads

7.7.2.1 In general, a transverse box structure is to be arranged at the top and bottom of watertight transverse bulkheads. In addition, vertical webs and horizontal girders are to be fitted on the bulkheads to support bulkhead stiffeners. The upper and lower ends of vertical webs are to be aligned with strength deck girders and double bottom side girders respectively. Where the depth to breadth ratio of the bulkhead is large, the scantlings of such vertical webs are to be determined by direct calculation.

Section 8 BOW SIDE STRUCTURE STRENGTHENING

7.8.1 General requirements

7.8.1.1 The bow (including forecastle) side structure is to be strengthened within 0.1L aft of the fore perpendicular above the summer load line. Where the maximum flare angle α at 0.15L from forward perpendicular (see Figure 7.8.1.3(1)) is greater than 40 degrees, the strengthened longitudinal extent is to be extended to 0.15L from forward perpendicular. The scantlings of side members in the strengthened area are to comply with the requirements of this Section.
7.8.1.2 In addition to the requirements of this Section, the bow side structure is to comply with the other relevant requirements in this PART.
7.8.1.3 The bow slamming head h_s under consideration is to be obtained from the following formula:

$$h_s = C_s \left(0.22 + 0.15 \tan\alpha\right)\left(0.4V \sin\beta + 0.6\sqrt{L}\right)^2 \quad \text{m}$$

where: C_s = 0.144 (C – 0.5h_1), and not to be greater than 0.8;
where: h_1 — vertical distance between summer load line and the point under consideration, in m, see Figure 7.8.1.3(1). For shell plating, the point is to be taken at centre of plate panel; for members, the point is to be taken at mid-span;
C — coefficient of wave, see 2.2.3.1 of this PART;
α — flare angle at the point under consideration, defined as angle (°) between vertical line and shell plating tangent in the cross section, see Figure 7.8.1.3(1);

β — entrance angle at the point under consideration, defined as angle (°) between centreline and shell plating tangent in the horizontal plane, see Figure 7.8.1.3(2);
V — maximum service speed, in kn;
L — length of ship, in m, but need not be taken as greater than 250 m.

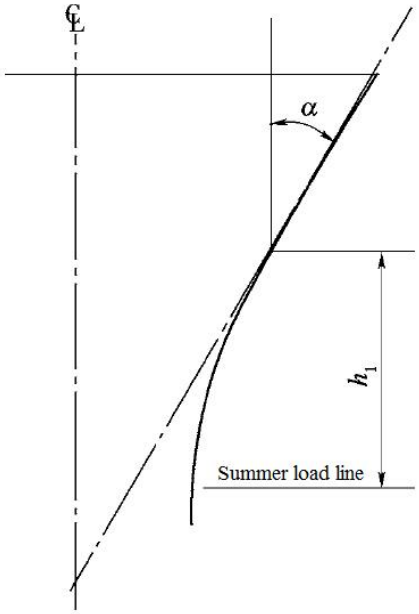

Figure 7.8.1.3(1)

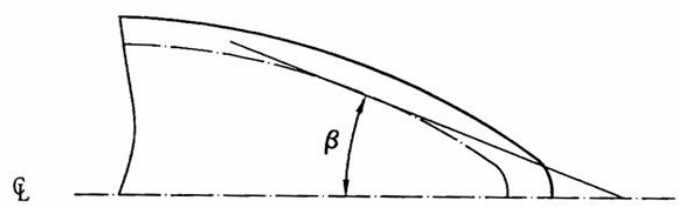

Figure 7.8.1.3(2)

7.8.2 Shell plating

7.8.2.1 The thickness t of shell plating is not to be less than that obtained from the following formula:

$$t = 3.2\, b_{r1}\, s\sqrt{h_s K} + 1.5 \quad \text{mm}$$

where: b_{r1} — coefficient, to be taken from the following, and not to be less than 0.72:

$$b_{r1} = 1.0 \qquad \frac{s}{l} \le 0.4$$

$$b_{r1} = 1.187 - 0.467\frac{s}{l} \qquad \frac{s}{l} > 0.4$$

where: s — spacing of secondary members, in m;
l — span of secondary member, in m;
h_s — bow slamming head under consideration, see 7.8.1.3 of this Section;
K — material factor.

7.8.3 Secondary members

7.8.3.1 The section modulus W and the web sectional area A of secondary members such as side longitudinals or side frames are not to be less than those obtained from the following formulae:

$$W = 2.7 s h_s l^2 K \quad \text{cm}^3$$
$$A = 0.38 b_{r2} l s h_s K \quad \text{cm}^2$$

where: $b_{r2} = 1 - \frac{s}{2l}$;
s — spacing of secondary members, in m;
h_s — bow slamming head under consideration, see 7.8.1.3 of this Section;
l — span of secondary member, in m;

K — material factor.

7.8.3.2 Where the angle between web plating and shell plating of secondary members such as side longitudinals or side frames is less than 70º, tripping brackets are to be provided at mid-span of the members to improve the transverse stability of plate panels.

7.8.4 Primary members

7.8.4.1 The section modulus W and the web sectional area A of primary members such as side horizontal girders or vertical webs are not to be less than those obtained from the following formulae:

$$W = 2.1Sh_s l^2 K \quad \text{cm}^3$$

$$A = 0.265Sh_s l K \quad \text{cm}^2$$

where: S — spacing of girders or webs, in m;

h_s — bow slamming head under consideration, see 7.8.1.3 of this Section;

l — span of girder or web, in m;

K — material factor.

Section 9 ADDITIONAL REQUIREMENTS FOR CONTAINER SHIPS OF GREATER THAN 250 M IN LENGTH

7.9.1 General requirements

7.9.1.1 This Section applies to large full container ships of more than 250 m in length.

7.9.1.2 Those not covered in this Section are to comply with the relevant requirements of Chapters 1 and 2 of this PART.

7.9.1.3 The bow (including forecastle) side structure strengthening is to comply with the requirements of Section 8 of this Chapter.

7.9.2 Longitudinal strength

7.9.2.1 The longitudinal strength is to comply with the requirements of Section 2 of this Chapter.

7.9.3 Deck structure

7.9.3.1 The deck structure is to comply with the relevant requirements of Sections 4 and 8, Chapter 2 of this PART.

7.9.3.2 The primary members of the deck structures in the region of container holds are to be verified by direct calculations.

7.9.3.3 The minimum thickness $t_{\min}$ of strength deck is to be calculated by the following formula:

$$t_{\min} = (0.02L + 5.5)\sqrt{K} \quad \text{mm}$$

where: L — length of ship, in m;

K — material factor.

7.9.3.4 Where the difference between the thicknesses of plating inside and outside the line of strength deck openings is large, two intermediate transition plates are at least to be fitted inside the line of opening. The difference between the thicknesses of adjacent plates, in general not exceeding 1/2 of the thickness of the thicker plate, is to be gradually reduced towards the inside of the line of opening. In general the higher edge of the thicker plate is tapered in way of connections with a ratio not more than 1:4.

7.9.4 Box cross deck structure

7.9.4.1 The box cross deck structure means the transverse box girder structure at the top of transverse bulkheads of container holds.

7.9.4.2 The width and structural scantling of box cross deck structure are to be verified by direct calculations.

7.9.4.3 During the initial design, the width of box cross deck structure may be calculated by the following formula:

$$b = \max(32.5B + 400, 1000) \quad \text{mm}$$

where: B — breadth of ship, in m.

7.9.4.4 In the strength deck plane, the minimum deck thickness of box cross deck structure is to be calculated by the following formula:

$$t = (10 + 0.01L)\sqrt{K} \text{ mm, but not to be less than 12 mm}$$

where: L — length of ship, in m, L need not be taken as greater than 300 m in calculation;

K — material factor.

7.9.4.5 The minimum thickness of bottom plating of box cross deck structure is to be calculated by the following formula:

$$t = 10s\sqrt{K} \quad \text{mm, but not less than 8 mm}$$

where: s — spacing of stiffeners, in m, to be taken not less than 0.95 m in calculation;

K — material factor.

7.9.4.6 The side plating of box cross deck structure (see Figure 7.9.4.6) is to comply with the following requirements:

(1) The thickness t_1 of side plating is not to be less than that obtained from the following formula:

$$t_1 = 12s \quad \text{mm, but not less than 10.5 mm}$$

where: s — spacing of stiffeners of side plating, in m.

(2) The thickness t_2 of the end insert plate is not to be less than that obtained from the following formula:

$$t_2 = 12s \quad \text{mm, but not less than 14.5 mm}$$

where: s — spacing of stiffeners of side plating, in m.

(3) The minimum scope of end insert plate is calculated by the following formulae:

$$a_1 = 1.75R \quad \text{m}$$

$$a_2 = 0.5b_s \quad \text{m}$$

where: R — radius of the hatch corners of the cargo hatchway opening in the strength deck plane, in m;

b_s — width of double side skin, in m.

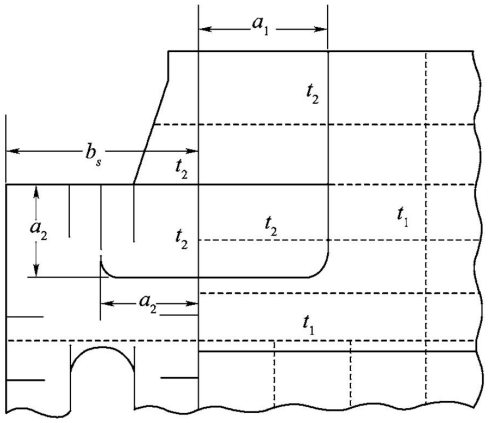

Figure 7.9.4.6

7.9.5 Strength deck openings

7.9.5.1 The corners of hatchway opening in the strength deck are to be rounded or rounded corners with negative radii. The design of hatch corners is to be verified by direct calculations.

7.9.5.2 For rounded corners near the ship's sides, their radius is not to be less than that obtained from the following formula:

$$R = 0.35 + 0.0005L \quad \text{m}$$

where: L — length of ship, in m.

7.9.5.3 The radius of rounded corners in way of the intersection of deck girders with box cross deck structures is not to be less than 0.25 m.

7.9.5.4 For strength deck, insert plates are required at the hatch corners, generally extending to the extent not less than the requirements of Figure 7.9.5.4. The thickness of insert plates is to be greater than or equal to that of adjacent strength deck. The strengthening of the strength deck at the hatch corners is to be verified by means of fatigue assessment.

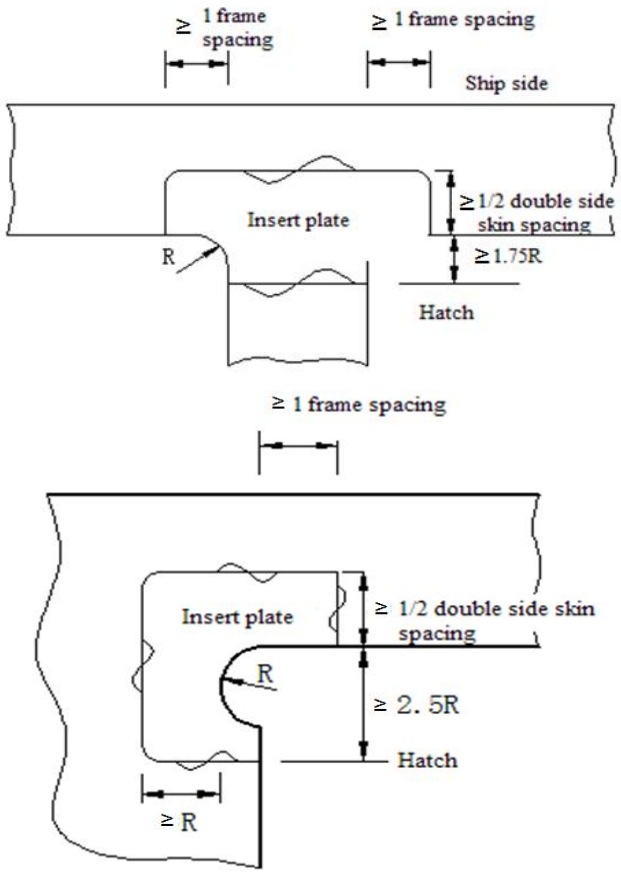

Figure 7.9.5.4

7.9.5.5 Large access openings are generally not to be arranged in the strength deck outside the line of hatch openings in the region of container holds.

7.9.5.6 Small openings, such as those for ventilation pipes or scuppers, are to be kept clear of hatch corners, ends of longitudinal hatch coamings, ends of box cross deck structures and other locations of stress concentration.

7.9.6 Hatch coamings of container hold

7.9.6.1 The hatch coaming is to be continuous over the entire opening area except for the engine room area. The ends of the coaming are to have an appropriate structural transition.

7.9.6.2 The structure of coaming is to comply with relevant requirements of Section 20 of Chapter 2 of this PART.

7.9.6.3 Hatch coamings are to be provided with brackets spaced not more than 3.15 m apart, and they are also to be provided with face plates. However, the spacing between brackets is not to exceed 6.3 m upon direct strength calculation. The brackets of hatch coamings are to be capable of effectively supporting the face plates. The toe ends of brackets are to terminate at the strength deck longitudinals. Brackets of hatch coamings in way of box cross deck structures are also to comply with 7.9.4.6 of this Section.

7.9.6.4 For face plates of hatch coamings, insert plates are required at the hatch corners, and the scope is shown in Figure 7.9.6.4. The thickness of insert plates is to be greater than or equal to that of adjacent face plates of hatch coamings. The strengthening of face plates of hatch coamings at hatch corners is to be verified by means of fatigue assessment.

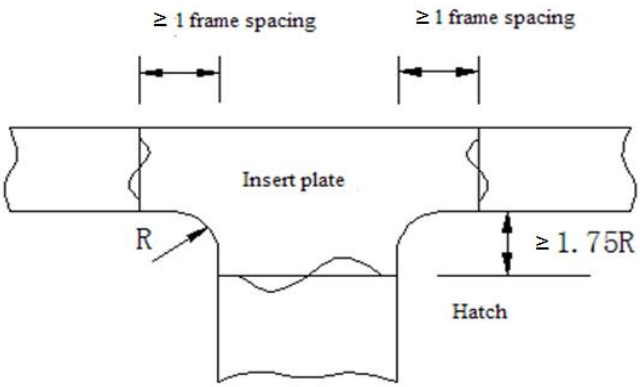

Figure 7.9.6.4

7.9.7 Shell plating

7.9.7.1 Except where stated by this Section, the shell plating is to comply with relevant requirements of Section 3, Chapter 2 of this PART.

7.9.7.2 In addition to 7.9.7.1 of this Section, the thickness of shell plating is not to be less than that obtained from the following formula:

$$t = \sqrt{LK} \quad \text{mm, but need not be greater than 16 mm}$$

where: L — length of ship, in m;

K — material factor.

7.9.7.3 The difference in thickness between the sheer strake and the adjacent shell plating is in general not to exceed 1/2 of the thickness of the thicker plate. In general the higher edge of the thicker plate is tapered in way of connections with a ratio not more than 1:4.

7.9.8 Structural arrangement of double side skin construction

7.9.8.1 Double side skins are to be fitted throughout the container hold area. The inner skin structure is to extend as far forward and aft as possible and effectively connected with the structures in way with adequate transition arrangements. The supporting members of inner skin are to be fitted in the double side skin, instead of in the container hold.

7.9.8.2 The inner skin is to be of continuous construction, and also maintained continuous in way of the engine room area. The inner skin may be stepped along the ship's length, considering the change of lines and arrangement of container bays. The scarfing arrangements in way of the steps are to be sufficient to ensure an efficient overlap of inner skin bulkheads having a length of not less than 3 frame spacings for transition.

7.9.8.3 Considering the change of lines and arrangement of container bays, the inner skin may be stepped horizontally in the vertical direction.

7.9.8.4 A transverse ring structure or vertical web is to be provided in line with the transverse watertight bulkheads of container holds in the double side skin. Watertight vertical webs are to be provided as far as practicable below the freeboard deck. Wash bulkheads are to be provided for ballast tanks.

7.9.8.5 A transverse ring structure or vertical web is to be provided in line with the transverse non-watertight pillar bulkheads of container holds in the double side skin.

7.9.8.6 A transverse ring structure or vertical web in the double side skin is to be provided in line with the floors in the double bottom.

7.9.8.7 Manholes are to be provided in vertical webs and horizontal girders. The manholes may either be round or elliptical. The long axis of elliptical manholes is to be vertical or along the length of the ship. Except for access openings, the holes on upper and lower adjacent horizontal girders are not to be on the same vertical line. The edge around the holes is to be strengthened.

7.9.9 Scantling of double side skin construction

7.9.9.1 The primary members of double side skin construction include side shell platings, vertical transverse webs, horizontal flats, inner skin longitudinal bulkhead platings. The scantling of primary members is to be verified by direct calculations.

7.9.9.2 The inner skin plating is to comply with the following requirements:

(1) The minimum thickness t of inner skin plating is to be calculated by the following formula:

$$t = 7 + 0.02L\sqrt{K} \quad \text{mm}$$

where: L — length of ship, in m, L need not be taken as greater than 300 m in calculation;
K — material factor.

(2) The inner skin plating is to comply with the requirements of 7.9.11.4 of this Section.

(3) The thickness t of inner skin plating forming boundary of tanks within 0.4 L amidships is, in addition to complying with the requirement of (4), not to be less than:

$$t = (4 + 0.6\frac{z - z_n}{D - z_n})s\sqrt{hK} + 2.5 \quad \text{mm, above the horizontal neutral axis}$$

$$t = \left(4 + 0.2\frac{z_n - z}{z_n}\right)s\sqrt{F_b hK} + 2.5 \quad \text{mm, below the horizontal neutral axis}$$

where: s — spacing of stiffeners, in m;
h — vertical distance, in m, measured from a third of the height from the lower edge of the plate in a strake to the top of the tank, or half the distance to the top of overflow, whichever is the greater;
D — moulded depth, in m;
Z_n — the height of horizontal neutral axis, from base line, of hull cross section, in m;
Z — the height of calculation point from base line, in m;
F_b — reduction factor, see 2.2.5.6, Chapter 2 of this PART;
K — material factor.

(4) The thickness t of inner skin plating forming boundary of tanks is not to be less than:

$$t = 4s\sqrt{hK} + 2.5 \quad \text{mm}$$

where: s — spacing of stiffeners, in m;
h — vertical distance, in m, measured from a third of the height from the lower edge of the plate in a strake to the top of the tank, or half the distance to the top of overflow, whichever is the greater;
K — material factor.

(5) The difference in thickness between the top strake of inner skin and the strake below is in general not to exceed 25 mm, and the maximum difference in thickness is not to exceed 35 mm. In general the higher edge of the thicker plate is tapered in way of connections with a ratio not more than 1:4.

7.9.9.3 Longitudinals (ship's side, inner skin) are to comply with relevant requirements of Chapter 2 of this PART. The minimum thickness of webs of longitudinals is 10 mm. Longitudinals are to penetrate continuously vertical transverse webs. Where side longitudinals are determined according to 2.7.5.1, Chapter 2 of this PART, the calculated pressure head h is to be obtained from following formulae:

$$h = 0.26C + d - \frac{Z}{D_F}d \quad \text{m, if } Z<D_F$$

$$h = 0.2C + 0.06C\frac{D - Z}{D - D_F} \quad \text{m, if } Z\geq D_F$$

where: D — moulded depth, in m;
D_F — minimum moulded depth, in m, in the middle of ship length, vertical distance from upper edge of flat keel to upper edge of side freeboard deck beam;
d — draught, in m;
C — coefficient, see 2.2.3.1, Chapter 2 of this PART;
Z— height of longitudinal to baseline, in m.

7.9.9.4 The thickness t of vertical transverse webs and horizontal flats forming boundary of tank is not to be less than:

$$t = 4s\sqrt{hK} + 2.5 \quad \text{mm}$$

where: s — spacing of stiffeners, in m;
h — vertical distance, in m, measured from a third of the height from the lower edge of the plate in a strake to the top of the tank, or half the distance to the top of overflow, whichever is the greater;
K — material factor.

The minimum thickness of vertical transverse webs and horizontal flats is to be 10 mm. The minimum thickness of watertight flats is 11 mm.

7.9.10 Double bottom

7.9.10.1 Except where stated by this Section, the double bottom structure is to comply with the relevant requirements of Section 6, Chapter 2 of this PART.

7.9.10.2 The primary members of double bottom include inner bottom platings, solid floors, girders and bottom platings. The scantlings and arrangements of primary members are to be verified by direct calculations.

7.9.10.3 Where mid-hold or quarter-length-of-hold supports for the double bottom structure are arranged, these are to take the form of an efficiently stiffened transverse box or open section structure.

7.9.10.4 The side plates of the duct keel are in general not to be spaced more than 2 m apart; However, where the direct strength assessment has been carried out, the maximum spacing between the side pates are not to be greater than 3 m.

7.9.10.5 Bottom and inner bottom longitudinals are to be fitted within the region of duct keels. The longitudinals are to be maintained continuous. The bottom longitudinals at the center line of the ship are to be suitably increased in scantling.

7.9.10.6 A strength frame ring is to be provided to the duct keel in the plane of solid floors and the middle of spacing of solid floors. For transverse girders of inner bottom in the strength frame ring, their section modulus is not to be less than 85% of those of ship's bottom. The section modulus W of transverse girders of ship's bottom is not to be less than that obtained from the following formula:

$$W = 10.6Sdl^2K \quad \text{cm}^3$$

where: S — spacing of the strength frame ring, in m;
d — draught, in m, to be taken not less than 0.66 times the vertical distance from the ship's bottom to the freeboard deck;
l — span, in m, to be taken as the spacing between two side plates;
K — material factor.

7.9.10.7 At least three side girders spaced apart generally not more than 3.5 m are to be fitted on each side of the centreline. Forward of 0.2L from the F.P., the spacing of side girders is not to be greater than 4 longitudinal spaces. Side girders are to be equally spaced and extend forward and aft as far as practicable.

7.9.10.8 Side girders are to be arranged and local stiffening is to be required under container corner seatings.

7.9.10.9 Solid floors in the region of container holds are to comply with the following requirements:

(1) Solid floors are to be fitted under transverse watertight bulkheads, transverse non-watertight pillar bulkheads/mid-hold supports, under container corners at hold quarter length locations and at other locations. Solid floors are in general to be spaced not more than 3.6 m apart.

(2) The thickness t of solid floors is to comply with relevant requirements of Section 6 of this Chapter and not to be less than that obtained from the following formula:

$$t = 10s\sqrt{\frac{R_{eH}}{235}} + 2.5 \quad \text{mm}$$

where: s — spacing of stiffeners, in m;
R_{eH} — yield stress of the material, in N/mm^2.

(3) In addition to complying with the requirements of (2) of this paragraph, the thickness t of watertight floors is to comply with relevant requirements of Section 6 of this Chapter.

7.9.10.10 The thickness t of inner bottom plating of container holds is not to be less than that obtained from the following formula:

$$t = 1.36(s + 0.66)\sqrt[4]{LdK^2} \quad \text{mm}$$

where: L — length of ship, in m;
d — draught, in m;
s — spacing of longitudinals, in m;
K — material factor.

The thickness t of inner bottom plating of container holds forming boundary of tanks is also to comply with the requirements for deep tanks in Section 13, Chapter 2 of this PART.

7.9.10.11 The section modulus W of inner bottom longitudinals of container holds is not to be less than that obtained from the following formula:

$$W = \frac{9.54dsl^2K}{2.1 - F_b} \quad \text{cm}^3$$

where: s — spacing of longitudinals, in m;
l — span of longitudinals, in m;
d — draught, in m;

F_b — reduction factor at calculation point;
K — material factor.

7.9.10.12 Strengthening of bottom forward is to comply with the relevant requirements of 2.15.3 of Section 15, Chapter 2 of this PART. In the strengthening region, for the strengthening of double bottom framed longitudinally, 2.15.3.3(1) of Section 15, Chapter 2 of this PART may not be required, but the spacing of plate floors is not to exceed 3.2 m or 4 times the spacing of longitudinals (whichever is the greater).

7.9.10.13 The thickness of center girders and side girders in region of container holds and the arrangement of supporting bracket of center girders are to comply with relevant requirements of Section 6 of this Chapter.

7.9.11 Transverse bulkhead of container hold

7.9.11.1 The primary members of transverse bulkhead include bulkhead platings, vertical webs and horizontal girders. The scantling of primary members is to be verified by direct calculations.

7.9.11.2 The web thickness t of girders of transverse bulkhead is not to be less than that obtained from the following formula:

$$t = 10s\sqrt{\frac{R_{eH}}{235}} + 0.5 \quad \text{mm , and not less than 9 mm}$$

where: s — spacing of web stiffeners, in m;
R_{eH} — yield stress of the material, in N/mm^2.

7.9.11.3 In general, a transverse box structure is to be arranged at the top and bottom of watertight transverse bulkheads. In addition, vertical webs and horizontal girders are to be fitted on the bulkheads to support bulkhead stiffeners. The upper and lower ends of vertical webs are to be aligned with strength deck girders and double bottom side girders respectively.

7.9.11.4 The scantlings of watertight transverse bulkhead platings and stiffeners are to be determined in accordance with the requirements of Section 12, Chapter 2 of this PART. The design head h is to be determined in accordance with the following requirements:

(1) For watertight transverse bulkhead platings, the design head h is to be determined in accordance with the following requirements (whichever is the greatest):

① vertical distance measured from the lower edge of the plate in a strake to the deepest equilibrium waterline obtained from the applicable damage stability calculations;

② vertical distance measured from the lower edge of the plate in a strake to the freeboard deck;

③ 2.5 m.

(2) For stiffeners, the design head h is to be determined in accordance with the following requirements (whichever is the greatest):

① vertical distance measured from the mid-span of stiffeners to the deepest equilibrium waterline obtained from the applicable damage stability calculations;

② vertical distance measured from the mid-span of stiffeners to the freeboard deck;

③ 2 m.

7.9.11.5 The minimum thickness of watertight transverse bulkhead platings is 8 mm.

7.9.11.6 One non-watertight transverse pillar bulkhead is to be fitted at every two 20 feet container bays along the ship's length in the container hold. The non-watertight transverse pillar bulkhead generally consists of vertical webs and horizontal girders.

7.9.12 Design verification

7.9.12.1 Except where otherwise stated, the design verification is not to lower the requirements for hull structures of this Section. The design verification of hull structures includes:

(1) direct calculation of strength assessment;

(2) fatigue strength assessment.

7.9.12.2 Direct calculations are to be carried out for strength assessment of the whole ship, primary structures of cargo holds and local structure of deck hatch corner under specified loads in accordance with Appendix 2 of this Chapter.

7.9.12.3 Fatigue strength assessment is to be carried out to the container hold structures in accordance with CCS Guidelines for Fatigue Strength of Ship Structure.

Section 10 LONGITUDINAL STRENGTH OF COMBINED BENDING AND TORSIONAL MOMENTS FOR SHIPS WITH LARGE OPENINGS

7.10.1 General requirements

7.10.1.1 For ships with large openings on deck, the longitudinal strength of combined bending and torsional moments is to be checked by the following:

(1) for length $L \leq 250$ m, the method defined in this Section or the method defined in (2);

(2) for length $L > 250$ m, the direct strength calculation of whole ship defined in Appendix 2;

7.10.1.2 Stresses are to be calculated for at least seven transverse sections in the cargo area as follows:

(1) at the forward end of the engine room;

(2) at the forward end of the opening length, opening length being the distance from the aft end of the cargo hatch before the engine room to the forward end of the foremost cargo hatch;

(3) at five intermediate sections within the opening length, at least three of which are to be within 0.4L amidships. The intermediate sections are to be arranged as far as possible in way of abrupt changes of longitudinal structures.

7.10.1.3 In addition, the stresses at transverse sections in way of abrupt changes of any other longitudinal structures beyond the requirements of 7.10.1.2 of this Section are to be calculated.

7.10.2 Wave bending moment

7.10.2.1 The vertical wave bending moment M_v is to be calculated by the following formula:

$$M_v = 9.81MKFL^2B(C_b + 0.7)\times 10^{-2} \qquad \text{kN·m}$$

where: L — length of ship, in m;

B — breadth of ship, in m;

M — distribution factor of bending moment, see 2.2.3.1 of Section 2, Chapter 2 of this PART;

C_b — block coefficient, taken as 0.6 for actual C_b less than 0.6;

$$K = 4.47(\frac{L}{1000} - 0.230)^2 + 0.817$$

F—factor, obtained from the following formulae:

$F = 9.4 - 0.95(\frac{300 - \mathrm{L}}{100})^{3/2}$, for $L \leq 300$ m;

$F = 9.4$, for $300 < L < 350$ m;

$F = 9.4 - 0.45(\frac{\mathrm{L} - 350}{100})^{3/2}$, for $350 \leq L \leq 500$ m.

7.10.2.2 The midship horizontal wave bending moment M_H is to be calculated by the following formula:

$$M_H = 0.431L^2B \qquad \text{kN·m}$$

where: L, B — see 7.10.2.1 of this Section.

M_H is equal to zero at ends, and the distribution of M_H along the length of the ship is to follow a straight line.

7.10.3 Torque

7.10.3.1 The hydrodynamic torque $M_T(x)$ at any cross section along the length of the ship is to be calculated by the following formula:

$$M_T(x) = 9.81e^{-0.00295L}\frac{LB^3C_T}{20000}(1.75 + 1.5\frac{\varepsilon}{D})(1 - \cos\frac{2\pi}{L}x) \quad \text{kN·m}$$

where: e — base of natural logarithms;

L — length of ship, in m;

B — breadth of ship, in m;

D — moulded depth, in m;

$C_T = 13.2 - 43.4C_W + 78.9{C_W}^2$;

where: C_w — the water plane area coefficient, need not be greater than $0.165 + 0.95C_b$;

ε — the distance measured from the shear centre below the baseline of the ship to the baseline, in m;

x — distance from any one cross-section to A.P., in m;

C_b — block coefficient, see 7.10.2.1 of this Section.

7.10.3.2 Cargo torque is caused by the uneven transverse distribution of cargoes, consumables or ballast. Unless any other loading case is specified, the cargo torque M_{TC} amidships is to be calculated by the following formula:

$$M_{TC} = 15.7Bn_Bn_t \quad \text{kN·m}$$

where: B — breadth of ship, in m;

n_B — number of stacks of containers in cargo holds amidships along the breadth of ship;

n_t — number of tiers of containers in cargo holds amidships, excluding the containers on deck and on hatch covers.

M_{TC} is equal to zero at ends and the distribution of M_{TC} along the length of the ship is to follow a straight line.

7.10.4 Stress calculation and criteria

7.10.4.1 The still water bending stresses σ_s is to be calculated by the following formula:

$$\sigma_s = \frac{M_s}{W_V} \times 10^3 \quad \text{N/mm}^2$$

where: M_s — permissible still water bending moment, in kN·m;

W_V — vertical bending section modulus at deck or bottom, in cm³, to be calculated in accordance with the relevant requirements of Section 2, Chapter 2 of this PART.

The permissible still water bending stress $[\sigma_s]$ at strength deck and keel is $88/K$, in N/mm², where K is material factor.

7.10.4.2 The combined vertical bending stress σ_c for ships under the heading wave condition is to be calculated by the following formula:

$$\sigma_c = \frac{M_s + M_V}{W_V} \times 10^3 \quad \text{N/mm}^2$$

where: M_s, W_v — same as defined in 7.10.4.1 of this Section;

M_V — vertical wave bending moment, in kN·m, see 7.10.2.1 of this Section.

The permissible combined vertical bending stress $[\sigma_c]$ is $157/K$ at the strength deck, in N/mm² and $150/K$ at the keel, in N/mm², where K is referred to 7.10.4.1.

7.10.4.3 The combined stress for ships under the oblique sea condition is to be the sum of the following stresses:

(1) The combined vertical bending stress σ_c is to be determined by the following formula:

$$\sigma_c = \frac{M_s + 0.6M_V}{W_V} \times 10^3 \quad \text{N/mm}^2$$

where: M_s, W_v — same as defined in 7.10.4.1 of this Section;

M_V — see 7.10.2.1 of this Section.

(2) The horizontal bending stress σ_H is to be determined by the following formula:

$$\sigma_H = \frac{yM_H}{I_H} \times 10^5 \quad \text{N/mm}^2$$

where: M_H — horizontal wave bending moment, in kN·m, see 7.10.2.2 of this Section;

y — horizontal distance from the point under consideration to centreline of the transverse section, in m;

I_H — horizontal moment of inertia, in cm⁴.

(3) The warping stress due to the hydrodynamic torque M_T and cargo torque M_{TC}.

The permissible combined stresses at strength deck and bottom is $157/K$, in N/mm², where K is referred to 7.10.4.1.

Appendix 1 CONTAINER SECURING

1 General Requirements

1.1 Application

1.1.1 Container stowage and securing requirements in this Appendix are based on containers manufactured in compliance with ISO 1496-1:2013.

This Appendix sets forth the survey requirements for the initial installation of container securing systems aboard vessels classed by CCS. It is to be clearly understood that no representation is made as to the ability of any container to withstand the loads allowed. The allowable loads have been derived from successful usage over a number of years and may exceed the design loads set forth in ISO Standard. It is the responsibility of the shipowner, or operator to ascertain that the containers used in the system can withstand the loads applied to them.

1.1.2 External dimensions, rated weights and corner fitting locations for common freight containers are given in Table 1.1.2.

External Dimensions, Rated Weights and Corner Fitting Locations for Common Freight Containers①

Table 1.1.2

Nominal Size	Container Designation	Length (mm)	Width (mm)	Height (mm)	Dimensions Center to Center of Corner Fittings(longitudinal) (mm)	Dimensions Center to Center of Corner Fittings(transverse)(mm)	Rated Weight (kg)
20 ft ISO668	1CC	6058	2438	2591	5853	2259	30480 (24000)②
	1C			2438			
	1CX			<2438			
40 ft ISO668	1AAA	12192	2438	2896	11985	2259	30480
	1AA			2591			
	1A			2438			
	1AX			<2438			
45 ft ISO668	1EEE	13716	2438	2896	11985 13509	2259	30480
	1EE			2591			
43 ft		13103	2438	2591	11985	2259	30480
48 ft		14630	2591	2908	11985 14422	2259	30480
53 ft		16154	2591	2908	11985 15947	2259	30480

Notes: ① The statistics of containers of ISO standard in the Table are determined according to ISO 668:2013.

② The rated weight for containers of 20 ft manufactured in accordance with the previous version of Amd 1:2005 of ISO 668:1995 is 24,000 kg. In the design of securing system, the recommended weights of empty containers are as follows:

20 ft container	2.5 t
40 ft container	3.5 t
43 ft and 45 ft container	4.0 t
48 ft and 53 ft container	4.5 t

1.2 Class notation

1.2.1 Ships other than container ships, fitted with container securing arrangements complying with the requirements of 1 to 5 of this Appendix, will be assigned the class notation “Equipped with Container Securing Arrangements”.

1.2.2 Where the ship has onboard container lashing program which has the ability to evaluate the safety of container stowage and lashing arrangement according to the requirements of 1 to 4 of this Appendix, and the lashing program is installed and maintained in accordance with the requirements of 6 of this Appendix, the notation CLC may be assigned upon application by the shipowner.

1.2.3 In addition to the requirements for CLC, the notation CLC(V) may be assigned, taking into account of the requirements for specific routes in 7.1 of this Appendix.

1.2.4 In addition to the requirements for CLC(V), the notation CLC(V,W) may be assigned, taking into account of the seasons and weather factors of specific routes in 7.2 of this Appendix.

1.3 Plans and documents

1.3.1 The following plans and documents are to be submitted for approval:
(1) General arrangement plan showing the disposition and design weights of the containers;
(2) Details of the cell guide structure, where fitted;
(3) Plans of lashing bridges, where fitted;
(4) Plans of stanchions on the deck, where fitted;
(5) Plans of securing arrangements of containers not associated with cell guides, where fitted;
(6) Details of securing devices (fixed and portable equipment, including safe working load);
(7) Arrangement plan of fixed securing devices and plan of hull supporting structure;
(8) Container securing manual/arrangement plan (container securing manual/arrangement plan approved by CCS is to be kept on board).

1.4 Limitation on ship handling

Improper ship handling related to course and speed or threshold phenomena like parametric rolling can create adverse loads acting on the ship and the cargo which are in excess of the loads determined on the basis of 4 of this Appendix. It is the responsibility of the master to apply good seamanship in order to mitigate excessive ship motions to reduce loads acting on the cargo stowage arrangements.

1.5 Definitions

1.5.1 **Bay**: An indication of the longitudinal position of a stack on ship. An athwartship block of containers associated with a hatch or hatch cover containing multiple stacks (or rows).
1.5.2 **Cell Guides**: A rigid securing system of vertical steel angles, spaced with some margin on container length and width that provides alignment and horizontal restraint for container stacks.
1.5.3 **Container Block**: A number of container stacks interconnected by double cones and/or bridge fittings.
1.5.4 **Container Stac**k: A single vertical stack of containers which may be secured by lock fittings, lock fittings plus lashings, or cell guides.
1.5.5 **Corner Fittin**g: A fixture, typically a casting, consisting of standard apertures and faces, which provide a common interface for handling and securing containers. It is an integral part of the container end frame structure and is generally in compliance with ISO Standard 1161. A similar fitting can also be found at intermediate posts located some distance from the end frame structure (such as at the 40-ft location on a 45-ft container).
1.5.6 **Corner Post**: Reinforced vertical structure between the corner fittings at the ends of containers designed to take the compressive and tensile forces exerted by lifting, stacking, and securing. Some containers also have intermediate 'corner' posts located some distance in from their ends at a nominal 40-ft spacing.
1.5.7 **Design Breaking Load**: The design breaking load of a component is determined by prototype testing. The design breaking load is not to be more than the last load recorded during the test prior to failure.
1.5.8 **Design GM Value**: The *GM* values used in the lashing calculations of containers are determined by the designer and specified in the container securing manual/arrangement plan. At least the minimum value and the maximum value are to be included. The minimum value is not to be less than the *GM* value in the condition where the maximum number of containers is loaded and the maximum value is not to be less than the maximum value of all expected container loading conditions. In the initial design, the minimum design *GM* value may be taken as 0.025*B*, and the maximum design *GM* value may be taken as 0.075*B,* where *B* is the breadth of the ship.
1.5.9 **ISO Freight Container**: Containers meeting the design dimensions and rated weights of ISO container standards such as:
ISO 1496-1 Series 1 freight containers
ISO 668 External dimensions and ratings
ISO 1161 Corner fittings and specifications
1.5.10 **Lashing Assembly**: A tension element made-up of a rod, wire rope or chain, a tensioning device, and a lashing point; used to secure a stack of containers.
1.5.11 **Lashing Point**: Fittings welded to the deck, hatch cover, stanchion, and lashing bridge, connecting lashing devices to the vessel structure or hatch covers. These include D-rings, lashing eyes plates, etc.
1.5.12 **Lashing Bridge**: An athwartship, elevated platform on deck from which container stacks on the hatch covers or deck may be secured with lashing assemblies.
1.5.13 **Safe Working Load (SWL)**: The SWL of a securing device is the design breaking load divided by an appropriate safety factor. The maximum resultant load upon a component is not to exceed the SWL.
1.5.14 **Proof Load**: A test load applied to a container securing device during production testing. The

minimum proof load is to be determined according to Table 2.2.1.
1.5.15 **Row/Stack**: An indication of the transverse position of a container in a stack.
1.5.16 **Racking**: Distortion of the container end or side due to horizontal forces.
1.5.17 **Securing Devices**: The general name of all fixed and portable devices used to secure and support containers.
1.5.18 **Tier**: An indication of the vertical position of a container in a stack. The first tier is the lowest position in the stack.
1.5.19 **Turnbuckle**: A specific type of Tensioning Device, used to connect the lashing rod and the lashing point.
1.5.20 **Twist lock**: A fitting inserted into corner fittings and used to secure containers stacked on top of each other in tension, compression, and shear.

1.6 Special Requirements
1.6.1 For containers not covered by ISO Standard 1496-1 as well as special ways of containers arrangement, the securing of such containers is to be considered according to the parameters and allowable loads as specified in 4.8 of this Appendix.

2 Materials and Testing

2.1 Materials
2.1.1 Steels used for the construction of the cell guides and the fixed securing devices attached to the hull are to comply with the relevant requirements of CCS Rules for Materials and Welding.

2.2 Prototype testing
2.2.1 Except for cell guides, prototype tests are to be carried out to determine the breaking loads of securing devices. The testing is to be carried out on at least two randomly selected samples of each item. The relationship between design breaking load and safe working load is to be as indicated in Table 2.2.1. No permanent deformation (other than that due to initial embedding of component parts) is to be induced by test loads up to the proof load given in the Table.

Design Breaking Loads and Proof Loads

Table 2.2.1

Item	Min. design breaking load (kN)		Min. proof load (kN)	
	$SWL \leq 400$	$SWL > 400$	$SWL \leq 400$	$SWL > 400$
Lashings:				
Wire rope	$3 \times SWL$			
Rod (higher tensile steel)	$2 \times SWL$		$1.5 \times SWL$	
Chain (mild steel)	$3 \times SWL$			
Chain (higher tensile steel)	$2.5 \times SWL$			
Other securing devices	$2 \times SWL$	$SWL + 400$	$1.5 \times SWL$	SWL + 200

Notes: ① The yield stress of higher tensile steel is not to be less than 315 N/mm^2.
② Breaking and proof loads for lashings of material other than steel will be specially considered.
③ *SWL* means the safe working load, in kN.

2.2.2 Where one of the two test samples fails before the design breaking load is reached, an additional sample is to be tested. The prototype testing may be accepted provided that the following conditions are met:
(1) The failure load is not less than 95% of the design breaking load;
(2) An additional sample is tested satisfactorily;
(3) The average failure load of the three samples, taking the additional sample into account, is not less than the design breaking load.
2.2.3 Securing devices may be tested in accordance with Table 2.2.3.

Test Mode

Table 2.2.3

Securing device	Test mode	Recommended minimum value (kN)		
		SWL	Proof load	Breaking load
Lashing rod (higher tensile steel)		180	270	360
Lashing rod		250	375	500
Lashing chain (higher tensile steel)		80	—	200
Lashing chain		100	—	300
Lashing wire		120	—	360
Turnbuckle		250	375	500
Twist lock		200	300	400
		250	375	500
Cone		200	300	400
Embedded stacking device		250	375	500
Stacking device		250	375	500
		200	300	400
D-ring		250	375	500
Lashing eye plate		250	375	500
Buttress		*SWL* is to be the individual calculation result of the stowage arrangement and test load is to be determined according to Table 2.2.1.		

2.3 Product testing

2.3.1 For production by a manufacturer in batches according to the plans and documents of the securing devices which have been accepted in the prototype testing, such products are to be subjected to testing according to one of the following requirements.

(1) Batch testing: For securing devices except for chain or wire rope lashings, one randomly selected sample from every 50 pieces, or from each batch if less than 50 pieces, is to be proof loaded to 1.5 times the safe working load. For chain or wire rope lashings, one randomly selected sample from every 50 pieces, or from each batch if less than 50 pieces, is to be tested to breaking.

(2) Individual testing: Every securing device is to be proof loaded to the safe working load of the item. In addition, one randomly selected sample from every batch of chain or wire rope lashings is to be tested to breaking prior to delivery.

2.3.2 For production test carried out in accordance with 2.3.1(1) of this Appendix, permanent deformation will not be accepted within the range of loading up to:

(1) $1.5 \times SWL$, where $SWL < 250$ kN;

(2) $SWL + 125$, where $SWL \geq 250$ kN.

2.3.3 In the event of premature failure or serious plastic deformation occurring in a test sample, two further samples are to be selected for testing. In the event that these samples are found to be satisfactory, the associated batch may be accepted.

2.3.4 For production test carried out in accordance with 2.3.1(2) of this Appendix, permanent deformation will not be accepted.

3 Stowage and Securing of Containers

3.1 General requirements

3.1.1 Containers are to be secured by one, or a combination of the following systems: corner locking devices, lashings, cell guides, buttresses, shores or equivalent structural restraint.

3.1.2 The method of securing containers is to be determined by calculating the forces acting on the containers in accordance with 4 of this Appendix and is to be capable of ensuring the strength of containers and securing devices.

3.2 Arrangements for stowage and securing on exposed decks

3.2.1 The stowage of containers on exposed decks is to satisfy the following requirements.

(1) The arrangements are to be such as to permit safe access for personnel in the necessary working of the ship, and to provide sufficient access for installation and inspection of the securing devices.

(2) Containers stowed on deck or on hatch covers are generally to be aligned in the fore and after direction.

(3) Containers are to be stowed so that they do not extend beyond the ship's side; adequate support is to be provided where they overhang hatch coamings or other deck structures.

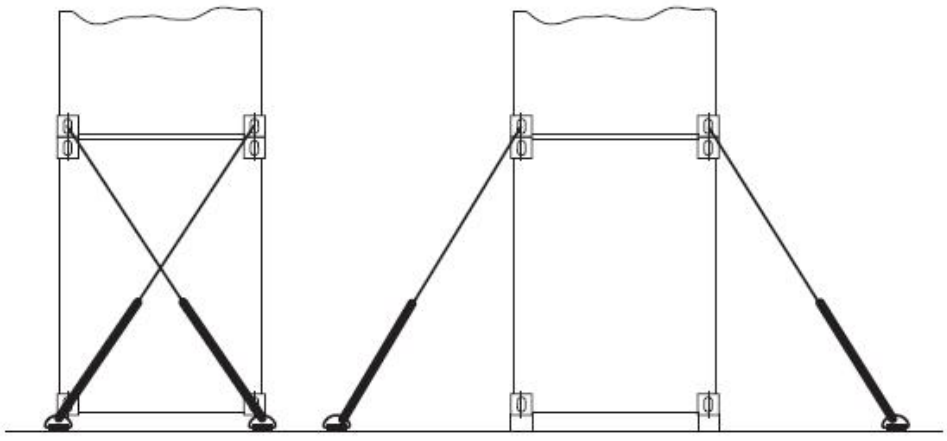
(4) Where containers are stowed on hatch covers, the covers are to be effectively restrained against sliding by approved type stoppers or equivalent.

3.2.2 The securing for containers stowed on the exposed deck is to comply with the following requirements:

(1) Twist locks and/or lashing arrangements are to be used for securing containers.

(2) In order to improve the lashing efficiency, the fixed lashing points can be arranged on the lashing bridge. In such case, the relative displacement between the structure of lashing bridge and the container stack is to be considered for calculating the lashing force.

(3) Normally, the internal lashing type is to be used for securing, as shown in Figure 3.2.2(a). For the external lashing type as shown in Figure 3.2.2(b), when the corner fitting connected to the lashing rod is in tension, due to the clearance existing between the twist locks and the container corner fittings, the twist locks will not be subject to the pulling force until such clearance between the twist lock and corner fitting of container is closed. In such case, the lashing rod may be broken as a result of excessive pulling force. When the external lashing type is selected, this situation is to be considered in securing calculation. Where no actual data is available, 12 mm vertical clearance is to be considered for semi-automatic twist lock and 20 mm vertical clearance for automatic twist lock.



(a) Internal lashing (b) External lashing

Figure 3.2.2 Internal lashing and external lashing

3.2.3 Cell guides may be used.

3.2.4 Up to a calculated remaining lifting force of 375 kN a vertical lashing can be applied for securing containers.

3.3 Arrangements for stowage and securing in holds

3.3.1 Without cell guides

(1) Containers are generally to be stowed in holds and 'tween decks in the fore and after direction.

(2) Containers may be secured by locking devices only or by a combination of locking devices, buttresses, shores or lashings, and the method of securing may be referred to 3.2 of this Appendix.
(3) Where the calculations indicate that remaining lifting forces could occur at any particular level, twist locks are to be fitted at that level. Elsewhere, consideration will be given to the use of double stacking cones.
(4) Where the calculations indicate that remaining lifting forces will not occur between containers at any level, consideration will be given to the use of double stacking cones in lieu of locking devices throughout.
(5) Buttresses are to be securely attached to the ship's structure. Where practicable, the attachment to the ship's structure is to include means for vertical adjustment of the buttresses to match container stacks of different heights.
(6) Shores of the compression type only may be permanently attached to the ship's structure or they may be hinged or portable and the ship's structure in way is to be reinforced as necessary. The shores are to abut the container corner fittings with minimal clearance.
(7) Adjacent stacks of containers are to be linked in line with buttresses or shores in order to transmit lateral loads, and the fittings used for these linkages are to be of adequate strength as buttresses or shores.
(8) The ship's structure supporting shores and buttresses is to be reinforced as necessary.

3.3.2 Using cell guides

(1) The cell guides are not to form an integral part of the ship's structure; the guide system is to be so designed as to keep it free from the main hull stresses.
(2) Cell guides are to be of robust construction; they are to be designed to resist loads caused by loading and unloading of the containers, to prevent shifting of the containers and to transmit the loads caused by motions of the ship into the main hull structure. The thickness of guides is not to be less than 12 mm.
The allowable stresses of cell guides are to be as follows (R_{eH} being the yield stress of the material, in N/mm^2):

Allowable shear stress: $[\tau] = 0.4R_{eH}$
Allowable normal stress: $[\sigma] = 0.67R_{eH}$

(3) Cell guides are generally to be fabricated from steel plate and rolled sections; the guides are to be adequately supported at their upper ends.
(4) Athwartship cross ties are to be fitted between cell guides as a spacing determined from the loading on the guides but, generally, not more than 5 m apart. Wherever possible, cross ties are to be arranged in line with the corners of the containers as stowed and are to be supported against fore and after movement at a minimum of two points across the breadth of the hold. Where, however, the maximum fore and after deflection in the cross tie can be shown not to exceed 20 mm, then one support point may be accepted.
(5) The intersection between cell guide and cross ties is to provide adequate torsional stability.
(6) Intermediate brackets are to be fitted to vertical cell guides at suitable intervals.
(7) Longitudinal tie bars may be required to be fitted where shown necessary by the force calculations for the structure. Where fitted, they are to comply with the requirements for spacing and deflection as specified in 3.3.2(4) of this Appendix.
(8) Where, at the sides or ends of holds, the guide rails are fitted to transverse or longitudinal bulkheads, the bulkhead is to be locally reinforced to resist the additional loads.
(9) The cell guides are to give a total clearance between the container and guide bars not exceeding 25 mm in the transverse direction and 40 mm in the longitudinal direction. Attention is to be given to the accuracy in fitting cell guides so as to ensure smooth loading and unloading of containers.
(10) A device to pre-centre the container and direct it into the cell guides is to be of robust construction, and is normally to be fitted at the top of the guide bars.
(11) Where containers of different height are stacked in the cargo holds, the horizontal force acting at the middle of each two cross ties needs to be considered for the strength of guides.

3.4 Mixed stacks of 20 ft and 40 ft containers

3.4.1 Where the cell guides are arranged for the carriage of 40 ft containers, provision may be made for the installation of temporary intermediate cell guides for 20 ft containers. The permanent structure is to be designed such that it is suitable for either loading pattern.
3.4.2 Alternatively, permanent means for the support of 20 ft containers at the mid-length of a cell arranged for 40 ft containers will be considered.
3.4.3 Where it is desired to stow 20 ft containers in the lower tiers without external support at the mid-bay location, the following requirements are to be complied with.
(1) Overall stacked container weights allowed for 20 ft containers stowed in cell guides with no 40 ft container overstowed can be derived from Tables 3.4.3(1) depending on the acceleration and the number of tiers in the stack.

(2) Overall stacked container weights allowed for 20 ft containers stowed in cell guides with at least one 40 ft container overstowed can be derived from Table 3.4.3(2) depending on the acceleration and the number of tiers in the stack.
(3) Racking forces acting on end walls of 20 ft containers stowed in the lowest tier at the mid-length of a cell arranged for 40 ft containers are not to exceed 185 kN. The orientation of the containers is to ensure as far as possible that all door ends or closed ends are facing in one direction. Weights listed in Table 3.4.3(1) and Table 3.4.3(2) apply to 20 ft containers the maximum rated weight of which is 30,480 kg.
(4) Stacking cones are to be fitted between each tier of the 20 ft containers and between the 20 ft containers and bottom of the hold to prevent transverse sliding.
(5) Where fore and aft tension/pressure adapter cones are used to link two 20 ft containers to equate to a 40 ft container, the storage of 40 ft containers above is not required.

Stowage Weights of 20 ft Containers (t)

Note: In the above table, "tiers" is the number of tiers of 20 ft containers and "a_t" the transverse acceleration of the stack in the intermediate tier. For example, where 7 tiers of 20 ft containers are stacked with no 40 ft containers overstowed, if the transverse acceleration of the stack in the intermediate tier a_t is 0.45g, then the overall weight of the stack is not to exceed 110.9 t, but the weight of container of each tier of stack may be different.

At least One Tier of 40 ft Containers Stowed above 20 ft Containers (t)

5	91.5	90.3	89.1	88.0	86.8	85.7	84.7	83.6	82.6	81.6	80.6
4	86.7	85.6	84.5	83.4	82.3	81.3	80.2	79.3	78.3	77.3	76.4
3	80.6	79.5	78.5	77.5	76.5	75.5	74.5	73.6	72.7	71.9	71.0
2	61.0	61.0	61.0	61.0	61.0	61.0	61.0	61.0	61.0	61.0	61.0

Note: In the above table, "tiers" is the number of tiers of 20 ft containers, excluding the number of 40 ft containers stacked on the top, and "a_t" the transverse acceleration of the stack in the intermediate tier. For example, where 7 tiers of 20 ft containers are stacked with at least a tier of 40 ft containers overstowed, if the transverse acceleration of the stack in the intermediate tier a_t is 0.45g, then the overall weight of the stack is not to exceed 162.7 t, excluding the number of 40 ft containers stacked on the top, but the weight of container of each tier of stack may be different.

4 Determination of Forces Acting on Containers and Strength of Securing Arrangements

4.1 General requirements

4.1.1 The forces acting on the containers are to be determined according to loading conditions and associated motions of the ship. The following forces are to be taken into account: inertial forces of the containers generated by accelerations due to roll, pitch and heave motions of the ship, static gravity forces, wind forces, forces imposed by the securing arrangements and wave impact forces.

4.1.2 The resultant force acting on the containers can be divided into three components as F_x, F_y and F_z, as shown in Figure 4.1.2, where ox is the central axis of roll and F_x, F_y and F_z act on the centre of the container, which means that the centre of gravity of the container is assumed to be at the centre of the container. In securing calculation, it may be accepted that the centre of gravity of the container is at 45% of container height.

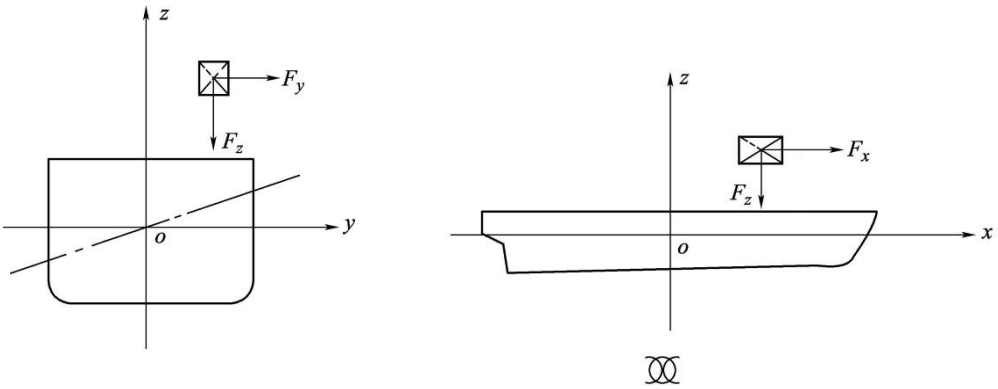

Figure 4.1.2 Forces Acting on Containers

4.2 Container securing acceleration

4.2.1 The transverse acceleration a_t for container securing calculation is calculated as follows:

$$a_t = (g + b_v) \cdot \sin\phi_m + b_h \cdot \cos\phi_m + (\frac{2\pi}{T_R})^2 \cdot \phi_m \cdot (z - z_{ROLL}) \quad \text{m/s}^2$$

where: g—gravity acceleration, to be taken as 9.81 m/s^2;
b_v—acceleration of vertical motion due to pitch and heaving, in m/s^2;
b_h—acceleration of transverse motion due to yawing and swaying, in m/s^2;
φ_m —rolling angle of ship, in rad;
T_R—rolling period of ship, in s;
z—height from container gravity center position to baseline, in m;
z_{ROLL}—height from ship rolling centerline to baseline, in m.

In above calculation formula of transverse acceleration, b_v and b_h are determined by main dimension, block coefficient and speed of ship, and rolling angle and rolling period are determined by main dimension and metacentric height of ship. Transverse acceleration a_t may be determined through CCS ship calculation system.

4.2.2 The vertical acceleration a_v for container securing calculation is calculated as follows:

$$a_v = 0.866 k_x \cdot g \qquad \text{m/s}^2$$

where: g—gravity acceleration, to be taken as 9.81 m/s^2;
k_x—longitudinal distribution coefficient which can be determined through CCS ship calculation systems.

4.2.3 The longitudinal acceleration a_l for container securing calculation is calculated as follows:

$$a_l = g \cdot (0.4 - 0.001 L_{BP}), \text{ but need not be less than 1.5 m/s}^2$$

where: g—gravity acceleration, to be taken as 9.81 m/s^2;
L_{BP}—length between perpendiculars, in m.

4.3 Forces acting on containers

4.3.1 The transverse force component F_y parallel to deck is to be calculated as follows:

$$F_y = G a_t + Q \qquad \text{kN}$$

where: G—gross weight of the container, in t;
a_t—transverse acceleration, in m/s^2, see 4.2.1 of this Appendix;
$Q = qA$, in kN, where q is the wind pressure, to be taken as 0.95 kPa for outermost containers at side (for containers at bottom, a splash force of 0.95 kPa is also to be taken into consideration), and as zero for others; A is the projected side area of containers bearing the wind pressure, in m^2. If the distance between adjacent container stacks is not more than 1 m, the wind load at containers inside can be omitted. If the distance between adjacent container stacks is 5 m or over, the wind load at containers inside is to be included in its entirety. If the distance is between 1 m and 5 m, linear interpolation is needed. If the exposed area is less than 1/3 of the side area, the wind load can be omitted.

4.3.2 The vertical force component F_z normal to deck is to be calculated as follows:
When checking the strength of the vertical supporting structure of containers:

$$F_z = G a_v \qquad \text{kN}$$

where: G — see 4.3.1 of this Appendix;
a_v — see 4.2.2 of this Appendix.

4.3.3 The longitudinal force component F_x parallel to deck is to be calculated as follows:

$$F_x = G a_l \qquad \text{kN}$$

where: G — see 4.3.1 of this Appendix;
a_l — see 4.2.3 of this Appendix.

4.4 Distribution and combination of forces acting on containers

4.4.1 The forces acting on each container are distributed as follows.

(1) The transverse component F_y of force is transmitted to the supporting point x from fore and after end walls of the container. The transverse force H_i transmitted from each end wall of the no. i container is to be obtained from the following formula:

$$H_i = F_{yi}/2 \qquad \text{kN}$$

The distribution of force H_i: if the center of gravity of the container is assumed to be the center of the container, H_i /2 acting on top of end wall and H_i /2 on bottom of end wall of the container; if the center of gravity of the container is assumed to be 45% height of the container, 0.45 H_i acting on top of end wall and 0.55 H_i on bottom of end wall of the container.

where: F_{yi} — transverse component of force, see 4.3.1 of this Appendix.

(2) The vertical component F_z of force is transmitted to the supporting structure from the four lower corners of the container. The vertical force *Vi* at each lower corner of the no. *i* container is to be obtained from the following formula:

$$V_i = F_{zi}/4 \qquad \text{kN}$$

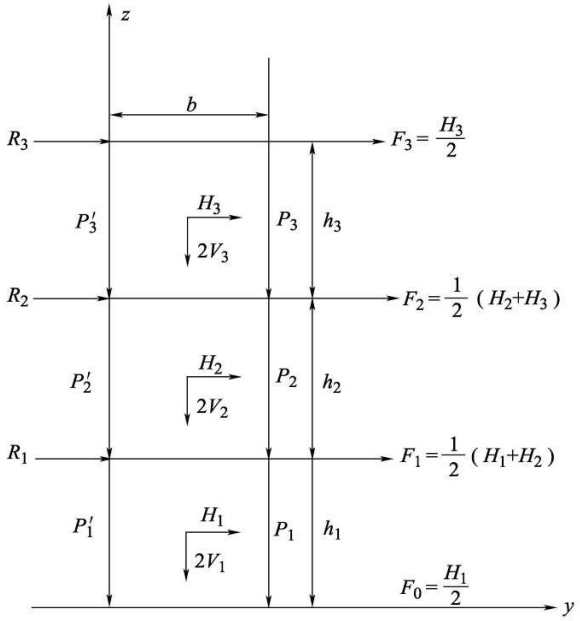
where: F_{zi} — vertical component of force of the no. *i* container, see 4.3.2 of this Appendix.

(3) The longitudinal component of force is transmitted to the supporting point *x* from both side walls of the container. The longitudinal component force L_i transmitted from each side wall of the no. *i* container is to be obtained from the following formula:

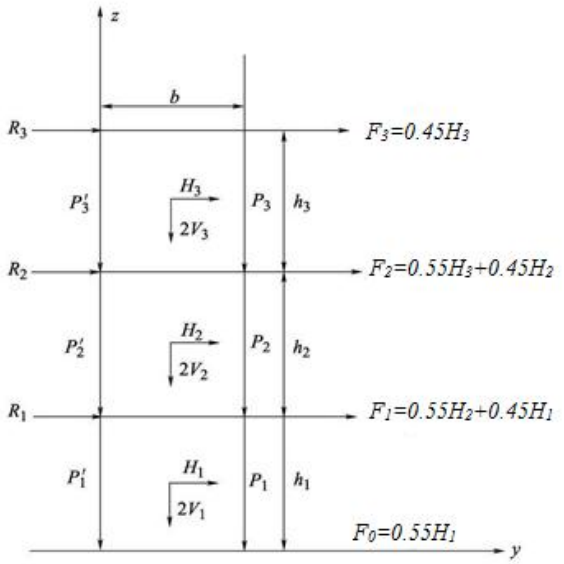
$$L_i = F_{xi}/2 \qquad \text{kN}$$

where: F_{xi} — longitudinal component of force of the no. *i* container, see 4.3.3 of this Appendix.

4.4.2 For containers in a three tier stack, the distribution of force at closed ends is given in Figure 4.4.2 and Table 4.4.2. The distribution of force on side walls may be treated in the same way.



(a) Gravity center at container center



(b) Gravity center at 45% height of container

Figure 4.4.2 Distribution of Force at Closed Ends of Containers

Distribution of Force at Closed Ends of Containers of Each Tier

Table 4.4.2

Force \ Tier	1st tier	2nd tier	3rd tier
Transverse racking force R_i per container end	$F_3 + F_2 + F_1$	$F_3 + F_2$	F_3
Maximum vertical pressure P_i per bottom corner	$V_3 + \frac{F_3}{b}(h_3 + h_2 + h_1) + V_2 + \frac{F_2}{b}(h_2 + h_1) + V_1 + \frac{F_1}{b} h_1$	$V_3 + \frac{F_3}{b}(h_3 + h_2) + V_2 + \frac{F_2}{b} h_2$	$V_3 + \frac{F_3}{b} h_3$
Minimum vertical pressure $P_i^{'}$ per bottom corner	$V_3 - \frac{F_3}{b}(h_3 + h_2 + h_1) + V_2 - \frac{F_2}{b}(h_2 + h_1) + V_1 - \frac{F_1}{b} h_1$	$V_3 - \frac{F_3}{b}(h_3 + h_2) + V_2 - \frac{F_2}{b} h_2$	$V_3 - \frac{F_3}{b} h_3$
Shear force S_i per bottom corner	$0.55(H_3 + H_2 + H_1)$	$0.55(H_3 + H_2)$	$0.55 H_3$

Note: Where $P_i^{'}$ indicates a negative value, it is a lifting force.

4.5 Calculation for lashings

4.5.1 Wire ropes, steel rods or steel chains may be adopted for lashings, the safe working load of which may be determined according to the breaking loads listed in Table 2.2.1 of this Appendix.

4.5.2 Figure 4.5.2 shows a two tier stack of containers, in which internal lashing is arranged to the second tier. If the center of gravity of the container is assumed to be the center of the container, for the selection of the effective sectional area A of the lashing, the residual racking force T (T being as required in 4.7.2 (2) of this Appendix) acting on the containers may be calculated in accordance with the following formula:

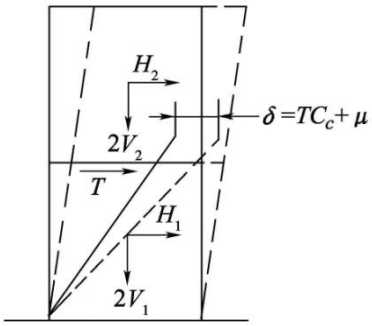


Figure 4.5.2 Two-Tier Stack

$$T = \frac{\frac{1}{2} H_1 + H_2 - \frac{AEI_y^2}{l^3}\mu}{\frac{AEI_y^2}{l^3} C_c + 1} \qquad \text{kN}$$

where:

H_1, H_2 — see 4.4.1 (1) of this Appendix;

l — overall length of lashing assembly, which is to include torsion element, turnbuckle and eye plate. l can be obtained as follows: $l = \sqrt{l_x^2 + l_y^2 + l_z^2}$, in mm;

l_x — longitudinal length component of lashing assembly, in mm;

l_y — transverse length component of assembly, in mm;

l_z — vertical length component of lashing assembly, in mm;

E — elastic modulus of lashings, to be taken as 10,000 kN/cm^2 for steel wire rope, 4,000 kN/cm^2 for steel chain based on its nominal diameter, 14,000 kN/cm^2 for steel rod (lashed to top of 1st tier containers or bottom of 2nd tier containers), or 17,500 kN/cm^2 for steel rod (lashed to top of 2nd tier containers or bottom of 3rd tier containers) or 19,000 kN/cm^2 for steel rod (lashed to top of 3rd tier containers or bottom of 4th tier containers);

A — effective sectional area of lashings, in cm^2;

μ — sliding at lower corners of container, in mm, to be taken as 4 mm for 1st and 2nd tier of container door end and 0 for closed end;

C_c — spring constant for container transverse frame, if no actual information available, 0.27 mm/kN for door end, 0.06 mm/kN for closed end and 0.168 mm/kN for side wall.

4.5.3 The lashing forces generated by the lashings are not to exceed the allowable loads as required in 4.7.2 (1) of this Appendix on container corner fittings.

4.6 Shoring forces

4.6.1 Where rigid shoring is used for the stowage of containers in holds without cell guide systems, the shoring forces may be determined by the following calculation.

The shoring forces Q_3 and Q_5 as shown in Figure 4.6.1 are to be calculated as follows:

$$Q_3 = \frac{1}{h_1}[H_4(h_1 - Z_4) + H_5(h_1 - Z_5)] + \frac{1}{h_2}[H_1Z_1 + H_2Z_2 + H_3Z_3] \quad \text{kN}$$

$$Q_5 = \frac{1}{h_1}(H_4Z_4 + H_5Z_5) \quad \text{kN}$$

where: for H_1, H_2, H_3, H_4 and H_5, see 4.4.1(1) of this Appendix.

Q_i is the shoring force for a stack of containers. Where there are n stacks of containers arranged in the transverse direction and the number n does not exceed 4, the shoring force is to be nQ_i; where n exceeds 4, the shoring force Q_i (n) may be calculated as follows:

$$\text{If } n-m \le 4, \quad Q_i(n) = Q_i \cdot \left[1 - \frac{(n-4)^2}{2 \cdot n \cdot m}\right]$$

$$\text{If } n-m > 4, \quad Q_i(n) = Q_i \cdot \left(\frac{8+m}{2 \cdot n}\right)$$

where: n—number of stacks using the same transverse support;

m—maximum tiers of all container stacks.

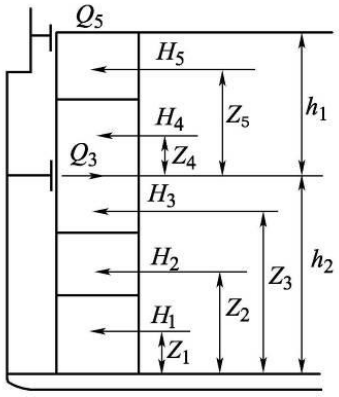

Figure 4.6.1 Rigid Shoring Forces

4.6.2 Where elastic shoring is used for the stowage of containers in holds, the shoring forces may be determined by the following calculation:

As shown in Figure 4.6.2, there are three elastic shoring points in one stack of containers, i.e. i, j and k; and the shoring forces are expressed as Q_i, Q_j and Q_k respectively. The shoring forces may be obtained according to the principle that the displacement of the elastic shoring points is equal to the total displacement of containers, with consideration being given to the mutual influence between the shoring forces. The shoring forces Q_i, Q_j and Q_k may be obtained as follows:

$$Q_k(C_{sk} + kC_c) + (kQ_i + kQ_j)C_c + \delta_k = C_c[(H_{k+1} + H_{k+2} + H_{k+3} + H_{k+4})k + \sum_{r=1}^{k} H_r(r - \frac{1}{2})]$$

$$Q_j(C_{sj} + jC_c) + jQ_iC_c + \delta_j = C_c[(H_{j+1} + H_{j+2})j + \sum_{r=1}^{j} H_r(r - \frac{1}{2})]$$

$$Q_i(C_{si}+iC_c)+\delta_i=C_c[H_{i+1}i+\sum_{r=1}^{i}H_r(r-\frac{1}{2})]$$

where: C_{si}, C_{sj}, C_{sk} — spring constants of shoring points i, j, k respectively, in mm/kN;
δ_i, δ_j, δ_k — initial gaps at shoring points i, j, k respectively;
C_c — see Table 4.5.2.

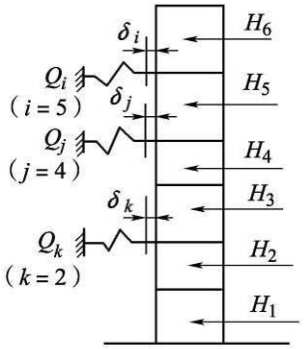

Figure 4.6.2 Elastic Shoring Forces

4.7 Allowable loads on containers

4.7.1 Forces acting on containers are not to exceed the allowable loads on containers irrespective of the methods of securing arrangements for containers.

4.7.2 As shown in Figure 4.7.2, the allowable loads on freight containers of ISO Standard Series 1 are as follows:

(1) lashing forces acting on the corner fittings:

the horizontal component of force on each end or side wall is not to exceed 150 kN or 225kN, the criteria value depends on the direction of horizontal component, see Figure 4.7.2a) for details;

the vertical component of force on each end or side wall is not exceed 300 kN;

in no case is the resultant of horizontal and vertical components of force to exceed 300 kN.

(2) Racking forces acting on end or side walls:

the transverse racking force on each end or side wall is not to exceed 150 kN;

the vertical racking force on each end or side wall is not to exceed 100 kN.

(3) Vertical tensile and compressive forces acting on the corner fittings:

the vertical tensile force acting at each top corner is not to exceed 250 kN;

the vertical tensile force acting at each bottom corner is not to exceed 250 kN;

the compressive force at each corner post is not to exceed 848 kN.

(4) Transverse compressive and tensile forces acting on the corner fittings:

the transverse compressive (tensile force) at each top corner of 20 ft containers is not to exceed 225 kN;

the transverse compressive (tensile force) at each top corner of 40 ft containers is not to exceed 340 kN;

the transverse compressive (tensile force) at each bottom corner of 20 ft containers is not to exceed 350 kN;

The transverse compressive (tensile force) at each bottom corner of 40 ft containers is not to exceed 500 kN.

Where a buttress supports the stack at an intermediate level, the total transverse compressive (tensile) force acting at the level is not to exceed 575 kN for 20 ft containers and 840 kN for 40 ft containers.

(5) For 45 ft containers, vertical compressive forces acting on the corner fittings:

if the container is stacked at 45 ft position and supported in 45 ft position, the compressive force at bottom corner post is not to exceed 942 kN;

if the container is stacked at 40 ft position and supported in 40 ft position, the compressive force at bottom corner fitting is not to exceed 404 kN.

For 45 ft containers, other allowable loads are the same as those for 40 ft containers.

(6) For containers with special dimensions (e.g. 43 ft, 48 ft and 53 ft), test results need to be submitted.

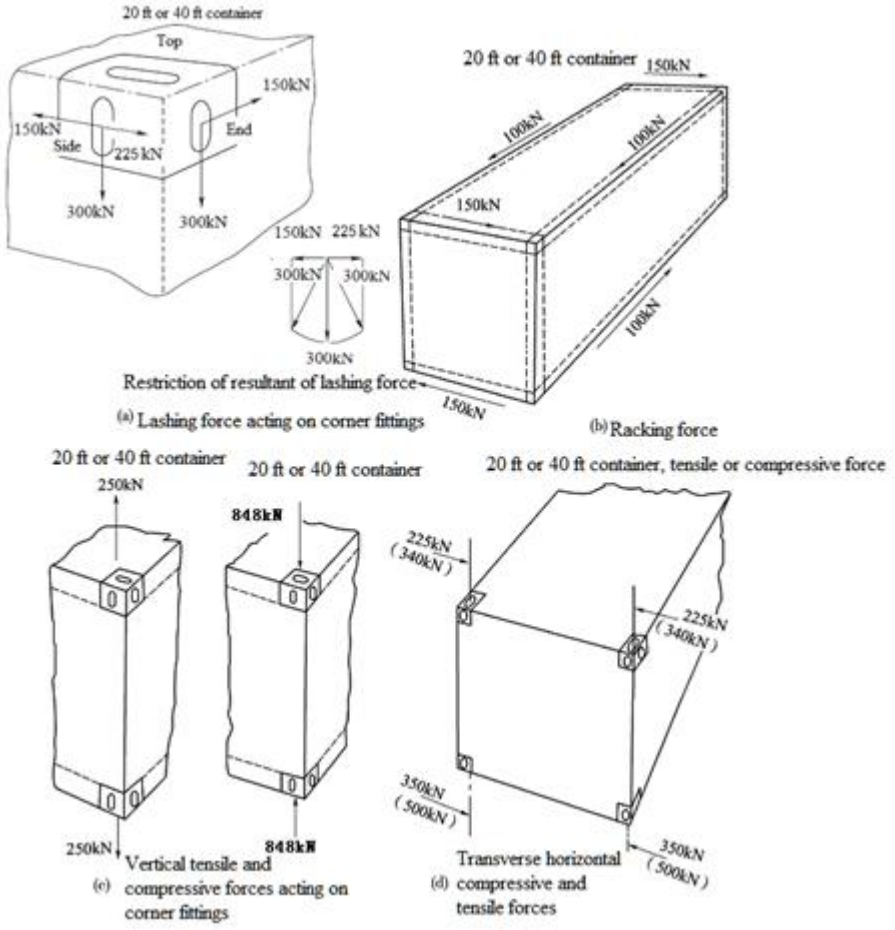

Figure 4.7.2 Allowable Loads on 20/40 ft Containers

4.8 Direct calculation of container securing

4.8.1 General requirements

4.8.1.1 2-dimensional beam model may be used to model containers and calculate the strength of containers and their lashings.

4.8.1.2 Each stack may be analysed separately unless there are connections between the stacks such as double cones or similar.

4.8.1.3 The flange thickness of twist locks or cones are to be included in clearances between container stacks.

4.8.2 Modelling of geometry

4.8.2.1 Beam elements are used to model container frames according to the dimension of containers.

4.8.2.2 The spring constant of the door end and of closed end are to be obtained respectively by adjusting the cross sectional area of the corner post as indicated by Figure 4.8.2.2:

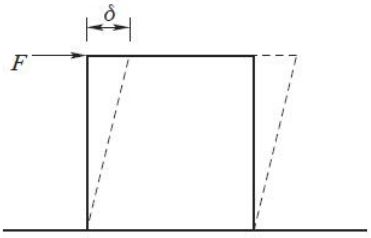

Figure 4.8.2.2 Spring Constant of Door End and of Closed End

For example: If the spring constant of the door end of the container is 0.291 mm/kN, when F=1,000 kN, the deflection of the frame is 291 mm.

4.8.2.3 Twist locks between two tiers of containers are to be modeled as rigid elements, with a hinge at one end to avoid transfer of bending moments.

4.8.2.4 Cones between two tiers of containers are to be modeled as non-linear elements capable of taking compression but not tension.

4.8.2.5 Lashing rods are to be modeled according to actual elastic modulus and cross sectional area.
4.8.3 Boundary conditions and loading
4.8.3.1 Elements attached to the ship structure are to be restricted from translation.
4.8.3.2 Loads should be applied as point loads in the corners of the containers. The transverse forces are applied to the top and bottom corners while vertical forces are only applied to the bottom corners of the container.
4.8.4 Calculation results
4.8.4.1 Results are to be extracted from the model to check whether the containers comply with the allowable loads of containers specified in 4.7 of this Appendix and whether the loads on the securing devices exceed their SWL.

5 Strength Evaluation of Container Securing Structure

5.1 General requirements
5.1.1 These requirements apply to the lashing bridge and stanchion structure and supporting structure of fixed securing devices (lashing eye plate, deck ring, etc.) on the deck of container ships.

5.2 Lashing bridge
5.2.1 The SWL of lashing rods (50% of the breaking load) is theoretically the maximum load to check the strength of lashing bridges.
5.2.2 To check the strength of a lashing bridge, loads are to be applied according to the condition where the maximum lashing force may occur in the container securing manual/arrangement plan, and the lashing force is to be obtained by calculating according to the container securing manual/arrangement plan. The lashing force is to be applied in line with the lashing rods and can be decomposed into force components in longitudinal, transverse and vertical direction. The lashing force is applied to the securing eye plate of the lashing bridge. In calculating lashing forces, the relative displacement between the lashing bridge and the container stacks are to be taken into account, which is not to exceed the values given in Table 5.2.2.

Relative displacement between lashing bridge and container stacks

Table 5.2.2

Lashing bridge of 1-tier container height	Lashing bridge of 2-tier container height	Lashing bridge of 3-tier container height
10 mm	25 mm	35 mm

5.2.3 In the initial design, forces may be applied according to the condition where the maximum lashing force may occur in reality. The lashing force is to be taken as 60% safe working load of each lashing rod (or other securing devices).
5.2.4 When checking the strength of lashing bridges, conditions where lashing forces are applied to forward and aft part lashing bridges together as well as respectively are to be calculated.
5.2.5 To better describe the force distribution of each structural part in each direction, strength checking of lashing bridge is to adopt 3-dimensional finite element structural analysis. The extent of the model, the elements and the boundary conditions are based on the following principles:
(1) The finite element model is to include all lashing bridges above the deck or hatch cover. The boundary conditions are to restrict all translations between elements and deck or hatch cover.
(2) The mesh size of the plate element is generally 100 mm × 100 mm, and triangle elements are to be avoided as far as possible in high stress areas and high stress changing areas.

5.3 Deck stanchion
5.3.1 In design of deck stanchion, the most critical conditions are to be taken into account, as well as the transverse load and vertical load acting on the stanchion.
5.3.2 Where lashing points are arranged on the stanchion, the horizontal and vertical components of lashing forces are also to be taken into account.

5.4 Fixed securing device
5.4.1 SWL of the connected securing device is to be used as the design load of supporting structure of fixed securing device.

5.5 Strength criteria
5.5.1 Allowable stresses for lashing bridge structures, deck stanchion structures and supporting structures

of fixed cargo securing devices under various conditions are as follows:

Allowable shear stress: $[\tau] = 0.4\ R_{eH}$

Allowable equivalent stress: $[\sigma] = 0.88\ R_{eH}$

where R_{eH} is the yield stress of the material, in N/mm^2.

6 Lashing Software

6.1 General requirements

6.1.1 All seagoing dedicated container ships are to be provided with lashing software complying with the requirements of this section.

6.1.2 Lashing software is an electronic data processing tool for onboard analysis of forces in container stacks and thereby reflects the parameters of the lashing system as described in the Cargo Securing Manual.

6.1.3 An approved lashing software is not a substitute for the approved Cargo Securing Manual. It is considered as a supplement to the approved Cargo Securing Manual.

6.1.4 The lashing software is a ship specific tool, and the results of the calculations are only applicable to the ship for which it has been approved.

6.2 Operation manual

6.2.1 An operation manual is to be provided for the lashing software and be kept on board, which is to be approved by CCS.

6.2.2 The language of the operation manual is to be the same as the language of the approved Cargo Securing Manual. A translation into another language considered appropriate may be required.

6.2.3 The operation manual is to contain descriptions and instructions, as appropriate, as per the following list:

(1) a general description of the lashing software;

(2) installation;

(3) function keys;

(4) menu displays;

(5) input and output data;

(6) required minimum hardware to operate the software;

(7) instruction on testing the lashing software with the test loading condition;

(8) a list of all terms, definitions, error messages and warnings likely to be encountered by the user; and

(9) in the case of error messages and warnings, there are to be unambiguous user instructions for subsequent action to be taken in each case.

6.3 Functional requirements

6.3.1 The lashing software is to be capable of calculating forces on containers and container securing equipment for any loading conditions for each container stack.

6.3.2 It is also to be capable of indicating the respective permissible values in order to assist the master in his/her judgement on whether the ship is loaded within the approved limits. The following parameters are to be presented:

(1) summary of ship particulars such as IMO No., length, and breadth;

(2) summary of loading conditions showing relevant input parameters such as draught and GM;

(3) stack and container positions;

(4) actual stack weights verified against permissible stack weights;

(5) relevant properties of securing devices, including permissible loads;

(6) accelerations and other external forces such as wind containers are exposed to;

(7) listing of all calculated forces on containers and container securing equipment, and evaluation of compliance of the calculated forces with the corresponding allowable values.

6.3.3 The container and lashing arrangements in each bay on deck and in holds are to be shown graphically.

6.3.4 The data are to be presented on screen and in hard copy printout in a clear and unambiguous manner.

6.3.5 A clear warning is to be given on screen and in hard copy printout if any of the allowable forces are exceeded.

6.3.6 In addition to the printout content, each page of the printout is to contain ship's identification, lashing software name and version number, date and time of the printout, and the title of the loading

condition. The printout is to be paginated sequentially, and the total number of printout pages are to be shown.
6.3.7 Units of measurement are to be clearly identified and used consistently.
6.3.8 Incorrect data input by the users, such as negative draught values, are to be prohibited. An error message is to be prompted on screen and in hard copy printout in a clear and unambiguous manner.

6.4 Test Loading Conditions

6.4.1 The lashing software is to be delivered with test loading conditions for selected stacks and bays covering applicable stowage patterns for containers of different dimensions contained in the Cargo Securing Manual. It is generally to cover the container stacking of the ship's bow, amidships and stern bay, including at least one lashing calculation for the conditions listed in the Cargo Securing Manual. For ships assigned the CLC (V) or CLC (V,W) notation, the corresponding additional conditions are to be supplemented.
6.4.2 The test loading conditions and their results are to be permanently stored in the computer where the lashing software is installed and be protected against unintentional or unauthorized modifications and access.

6.5 Approval of Lashing Software

6.5.1 The lashing software is subject to approval and is to include:
(1) verification of type approval, if any;
(2) verification that the latest ship data has been used;
(3) verification and approval of the test loading conditions and their results;
(4) verification if requirements of 6.3 are satisfied;
(5) checking of proper installation, and verification of the instrument on board in accordance with the approved test loading conditions;
(6) checking the availability of the operation manual on board.
6.5.2 In case of modifications implying changes in the ship’s design or container securing arrangement, the software is to be modified accordingly and re-approved.
6.5.3 Any changes in software version related to the container securing calculations are to be reported and be approved.
6.5.4 Upon installation, the lashing software is to be verified with the approved test loading conditions in the presence of surveyor. It is to be checked that the operation manual for the lashing software is available on board.
6.5.5 Verification does not absolve the shipowner of responsibility for ensuring that the information supplied into the lashing software is consistent with the current condition of the ship and approved Cargo Securing Manual.

6.6 Acceptable Tolerances

6.6.1 The results of the lashing software are compared with those of the CCS plan approval software. The tolerance of the accuracy of the results from the lashing software is to be below 1.0% of the allowable values. However, deviations may be accepted provided that there is a satisfactory explanation for the deviation and that there will be no adverse effects on the safety of the ship.

6.7 Annual and Special Survey

6.7.1 At each annual and special survey, it is to be checked that the operation manual is available on board.
6.7.2 The lashing software is to be checked for accuracy annually by the ship's Master by applying the test loading conditions. If the surveyor is not present for lashing software check, a copy of the test loading condition results obtained by this check is to be retained on board as documentation of satisfactory testing for the surveyor's verification at the next scheduled survey.
6.7.3 At each special survey this checking is to be done in the presence of surveyor.

7 Specific Route and Season

7.1 Transverse acceleration for specific route

7.1.1 For container securing of specific route, transverse acceleration a_{vt} is to be calculated as follows:

$$a_{vt} = a_t \cdot f_{route} \qquad \text{m/s}^2$$

where: a_t — transverse acceleration calculated according to 4.2.1 of this Appendix, in m/s^2;

f_{route} —specific route factor.

7.1.2 For each specific route, CCS will determine route factor f_{route} by statistical calculation of ship motion. CCS will develop specific wave scatter diagram based on acceptable wave statistical data to obtain f_{route}. For each specific route, latitude and longitude coordinates of a series of points along the route is to be provided by the shipowner or the information on sea areas passed by the route is to be provided. Division of sea areas and statistical data of wave in sea area are to be agreed by CCS. For each passed sea area, at least one point is to be given. If possible, time percentage for each passed sea area is to be provided.

7.1.3 For container securing of short voyage (port to port, navigation time within 72 hours), the specific route factor may be calculated as follows:

$$f_{route} = 1 - (H_s - 13)^2 / 240$$

where: H_s — the maximum expected significant wave height on the route during the navigation time, in m.

7.2 Transverse acceleration for specific season

7.2.1 For container securing of specific season, transverse acceleration a_{wt} is to be calculated as follows:

$$a_{wt} = a_{vt} \cdot f_{season} \qquad \text{m/s}^2$$

where: a_{vt} — transverse acceleration of specific route which is calculated in accordance with 7.1.1 of this Appendix, in m/s^2;

f_{season}—specific season factor.

7.2.2 Specific season factor f_{season} is the ratio of transverse acceleration calculated in accordance with the wave statistical data of a specific route in different seasons to transverse acceleration calculated in accordance with the wave statistical data throughout the year.

8 Approval and Certification of Container Securing Systems

8.1 General requirements

8.1.1 All seagoing dedicated container ships are to comply with the requirements of this section.

8.1.2 It is important for the safety of the ship and the protection of the cargo and personnel that the cargo is secured properly especially accounting for strength of the supporting structures and securing fittings. Hereto, a scope containing the following for approval and/or certification of container securing systems is defined:

(1) fixed and portable container securing fittings;

(2) arrangement plan of fixed container securing fittings;

(3) drawings of container supporting structures (container stanchions, hatch covers, lashing bridges, and cell guides, if any);

(4) cargo safe access plan;

(5) container stowage and securing plan;

(6) lashing software.

8.2 Fixed and Portable Container Securing Fittings

8.2.1 Fixed container securing fittings are used to secure and support containers and are permanently welded to the ship structure.

8.2.2 Portable1 container securing fittings are used to secure containers and are not categorised as fixed container securing fittings.

8.2.3 Minimum Breaking Load corresponds to the minimum load at which the first crack appears in the tested representative samples.

8.2.4 Minimum Proof Load corresponds to the test load below which visible permanent deformation is not allowed.

8.2.5 Drawings of fixed and portable container securing fittings are to show dimensions, materials, design loads, and manufacturer's markings.

8.2.6 Each fixed and portable container securing fitting type is subject to prototype testing to determine the minimum breaking loads. The minimum breaking load obtained from prototype testing is to be equal to

or exceed the design minimum breaking load. Requirements for prototype testing are given in 2.2 of this Appendix.

8.2.7 Fixed and portable container securing fittings are subject to production testing prior to delivery or installation. A number of samples from a batch of the container securing fittings is to be loaded to minimum proof load of the fittings. The production testing approval documents of delivered container securing fittings are to be kept on board and may be included in the approved Cargo Securing Manual. Requirements for production testing are given in 2.3 of this Appendix.

8.2.8 The plan detailing the arrangement of the fixed container securing fittings is to be approved. The arrangement plan is to include the following for all areas where the fittings are installed:

(1) The type of fixed container securing fittings such as container foundations and lashing eye plates;

(2) Unambiguous location of installed fittings such as their location relative to clearly described locations of the ship structures.

8.3 Drawings of Container Supporting Structures

8.3.1 The drawings of the structures necessary for conducting container stowage and securing are subject to approval. The drawings are to be detailed enough to allow their model generation for structural analyses. A plan is to be provided showing all relevant design loads for structural assessment of the container supporting structures and their foundations.

8.3.2 Structures involved in container stowage and securing include hatch covers, container stanchions, lashing bridges and cell guides.

8.4 Cargo Safe Access Plan

8.4.1 The cargo safe access plan is to be examined for its compliance with the requirements prescribed in MSC.1/Circ.1353/Rev.2 (refer to CCS Guidelines for the Preparation of the Cargo Securing Manual).

8.5 Container Stowage and Securing Plan

8.5.1 If the stowage and securing plan, as referred to in MSC.1/Circ.1353/Rev.2 4.2.1 and 4.2.2 (refer to CCS Guidelines for the Preparation of the Cargo Securing Manual), is required by the Administration, the plan is subject to approval in accordance with 8.5.2 and 8.5.3.

8.5.2 The container stowage plan is to include at least the following information for each container type the ship is designed for:

(1) longitudinal and athwartship views of under deck and on deck stowage locations of containers including reefers as appropriate;

(2) alternative stowage patterns for containers of different dimensions;

(3) maximum stack masses;

(4) maximum stack heights with respect to approved sight lines; and

(5) maximum nominal container capacity.

8.5.3 The container securing arrangement plan is to contain all information necessary to prepare lashing calculations. The container securing arrangement plan is to include at least the following information:

(1) summary of ship particulars such as IMO No., length and breadth;

(2) summary of loading conditions showing relevant input parameters such as draught and GM;

(3) longitudinal views of under deck and on deck stowage locations of containers as appropriate showing nominal capacity;

(4) maximum stack masses;

(5) relevant properties of securing fittings, including permissible loads;

(6) graphical presentation of container and lashing arrangements in each bay on deck and in holds for sample loading conditions for each container type the ship is allowed to carry;

(7) stack total mass and the sequence of masses in a stack;

(8) minimum quantity of fittings required to secure containers for the presented sample loading conditions.

8.6 Lashing Software

8.6.1 If the ship is provided with lashing software on board, the approval is to follow the requirements of Section 6 of this Appendix.

Appendix 2 DIRECT STRENGTH CALCULATION OF CONTAINER SHIPS

1 General

1.1 Application

1.1.1 This Appendix applies to direct strength calculations of container ships as required by this Chapter.

1.1.2 For those not covered in this Appendix, the relevant requirements of Section 5, Chapter 1 of this PART are to be complied with.

2 DIRECT CALCULATIONS OF STRENGTH OF PRIMARY STRUCTURES OF CARGO AREA

2.1 General requirements

2.1.1 The direct strength calculations for cargo holds are applicable to the evaluation of the strength of the following primary structures within cargo area in typical loading conditions:

(1) double bottom structure (bottom plating, inner bottom plating, girders, floors);

(2) double side structure (side shell plating, inner hull plating, longitudinal stringers and transverse web frames);

(3) Transverse bulkhead structure (transverse bulkhead plating, bulkhead webs);

(4) Deck structure (deck, torsion box).

2.1.2 Where fuel oil tanks are arranged between cargo holds amidships, strength evaluation is to be carried out for fuel oil tank area in accordance with 2.8 of this Appendix.

2.2 Structural modeling

2.2.1 Unless stipulated otherwise in this Appendix, see Section 5, Chapter 1 of this PART for requirements for structural modeling.

2.2.2 Normally, the longitudinal extent is to cover the length of 1/2 hold + 1 hold + 1/2 hold within the cargo area amidships, namely the length of one 40 ft bay + two 40 ft bays + one 40 ft bay. The vertical extent is to be taken up to the hatch coaming. A full-breadth model is to be required for transverse extent.

2.2.3 The model is generally to cover transverse watertight bulkheads and transverse support bulkheads. The transverse support bulkheads are at both ends and the middle of the model, and typical finite element models are shown in Figures 2.2.3(1) to (3).

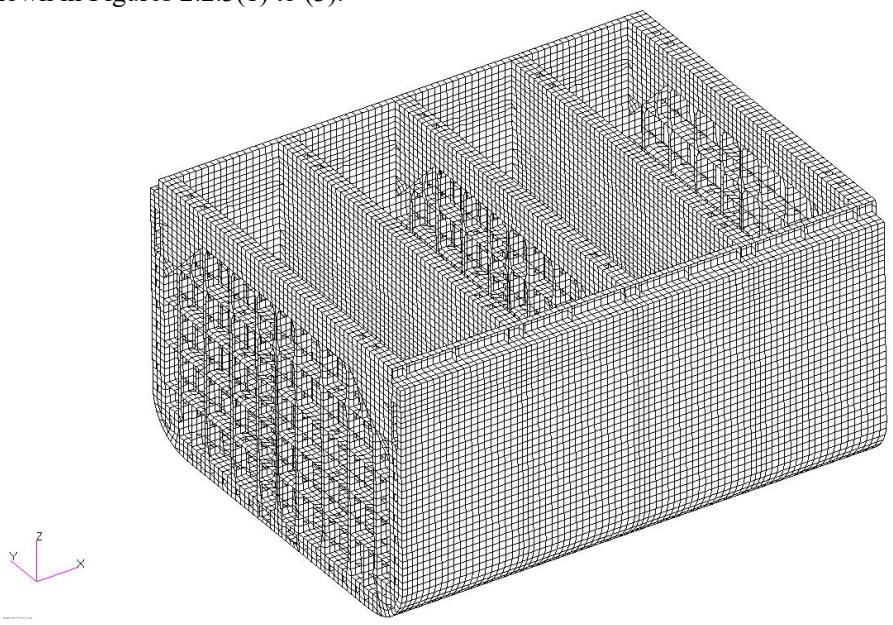

Figure 2.2.3(1) Typical finite element model

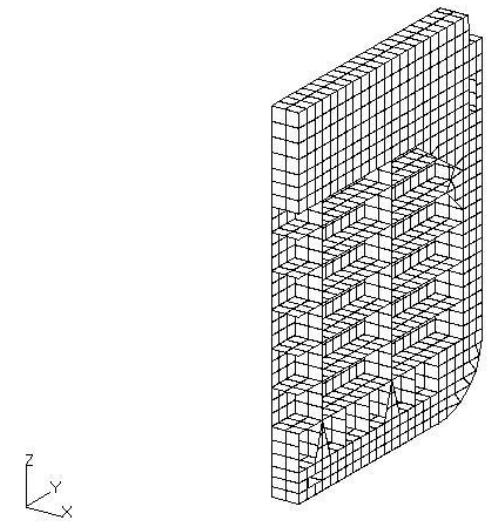

Figure 2.2.3(2) Typical finite element model of watertight transverse bulkhead (half-breadth)

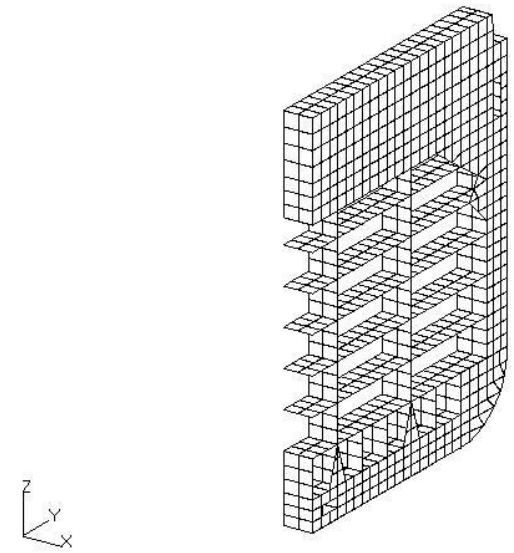

Figure 2.2.3(3) Typical finite element model of transverse support bulkhead (half-breadth)

2.3 Design loads

2.3.1 Unless stipulated otherwise in this Appendix, see Section 5, Chapter 1 of this PART for design loads.

2.3.2 The global loads include still water bending moment and wave bending moment. The still water bending moment M_S is to be taken as the permissible hogging moment $\overline{M}_{S-Hog}$ and permissible sagging moment $\overline{M}_{S-Sag}$ provided by the designer. Vertical wave bending moment M_W includes hogging wave bending moment M_{W-Hog} and sagging wave bending moment M_{W-Sag}, is to be calculated in accordance with 7.2.2.3 of Section 2 of this Chapter.

2.3.3 Local loads include:

(1) hydrostatic pressure;

(2) hydrodynamic wave pressure;

(3) self-weights of hull structure and containers;

(4) dynamic loads of hull structure and container induced by the ship's motions, see 2.3.5 for the acceleration of ship's motions.

2.3.4 External hydrodynamic wave pressure is an additional pressure induced by local wave loads,

consisting of hydrodynamic wave crest pressure and hydrodynamic wave trough pressure. See 1.5.3.3(4) and (5) of Chapter 1 of this PART for hydrodynamic wave crest pressure p_{hd}. The hydrodynamic wave trough pressure p_{hd1} is to be calculated as follows, the distribution is shown in Figure 2.3.4.

$$p_{hd1} = \max\left(-p_{hd}, \rho_w g\left(z - d_1\right)\right) \quad \text{KN/m}^2$$

where: p_{hd} — to be taken in accordance with 1.5.3.3(4) of Chapter 1 of this PART;

ρ_w — density of seawater, taken as 1.025 t/m^3;

g — acceleration due to gravity, g = 9.81 m/s^2;

z — vertical distance from calculation point to baseline, in m;

d_1 — draught in the considered load condition, in m.

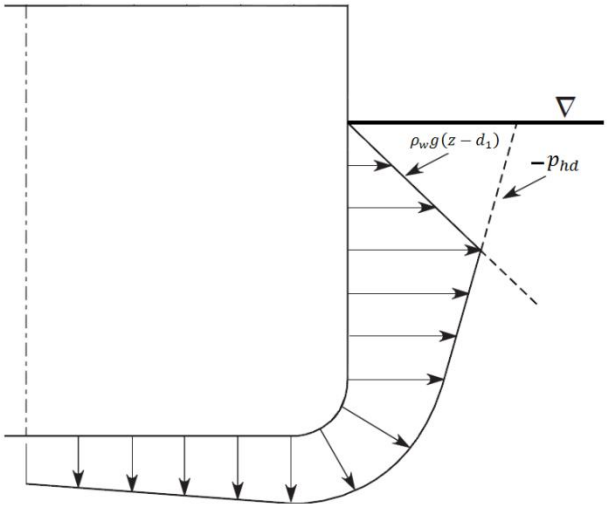

Figure 2.3.4 Distribution of hydrodynamic wave trough pressure on transverse section of the hull

2.3.5 The vertical acceleration a_v induced by the ship's motions is to be calculated as follows, positive downwards:

$$a_v = f_{LC}(C_{ZH}a_z - C_{ZP}a_p(x - 0.45L)) \quad \text{m/s}^2$$

where: f_{LC} — coefficient, to be taken as follows:

= -1.0 where the considered load condition is sagging condition;

= 1.0 where the considered load condition is hogging condition;

C_{ZH} — load combination factor of heave acceleration, C_{ZH} =0.15-0.5 f_T, $f_T = d_1/d$;

a_z — to be calculated in accordance with 1.5.2.1(3) of Chapter 1 of this PART;

C_{ZP} — load combination factor of pitch acceleration, taken as 0.7;

a_p — to be calculated in accordance with 1.5.2.1(5) of Chapter 1 of this PART;

x — X coordinate of the calculation point, in m;

L — length of the ship, in m.

The longitudinal acceleration a_1 induced by the ship's motions is to be calculated in accordance with 1.5.2.2(7) of Section 5, Chapter 1 of this PART and the speed is to be taken as half of the maximum service speed.

2.4 Loading conditions

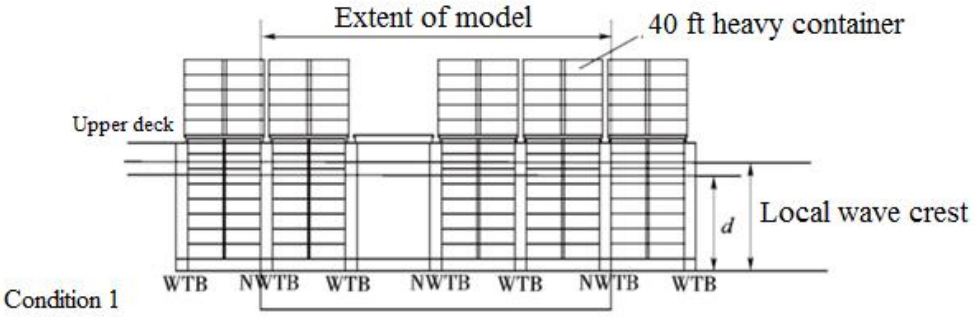
2.4.1 The applicable loading conditions are to be checked according to Table 2.4.1. For more severe loading conditions in the loading manual not covered by the Table, direct strength calculation is to be carried out. Figure 2.4.1 shows various loading conditions.

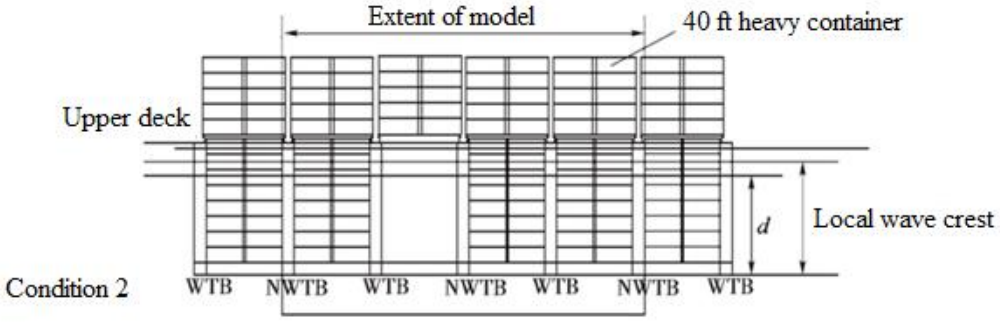
Loading Conditions **Table 2.4.1**

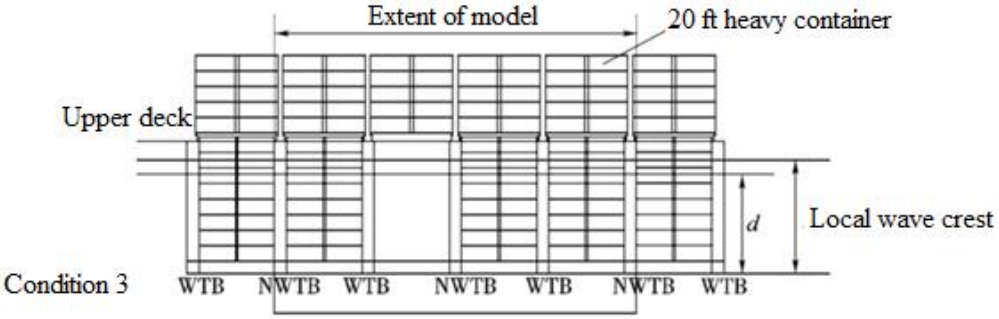
Loading condition	Condition description	Still water bending moment	Wave bending moment	Draught	hydrodynamic wave pressure	Container weight	dynamic acceleration of hull structure and containers
1	Empty within one 40 ft bay and hatch covers over the bay; full within other bays and hatch covers	$\overline{M}_{s-Hog}$	M_{w-Hog}	d	p_{hd}	40ft heavy container	a_v
2	Empty within one 40 ft bay and full on hatch covers over the bay; full within other bays and hatch covers	$\overline{M}_{s-Hog}$	M_{w-Hog}	d	p_{hd}	40ft heavy container	a_v
3	Empty within one 40 ft bay and full on hatch covers over the bay; full within other bays and hatch covers	$\overline{M}_{s-Hog}$	M_{w-Hog}	d	p_{hd}	20ft heavy container	a_v
4	Full within hold of all holds and on all hatch covers	$\overline{M}_{s-Sag}$	M_{w-Sag}	$0.9d$	p_{hd1}	20ft heavy container	a_v
5	Full within hold of all holds and on all hatch covers	$\overline{M}_{s-Hog}$	M_{w-Hog}	d	p_{hd}	40ft light container	a_v
6	Full within hold of all holds and on all hatch covers	$\overline{M}_{s-Hog}$	M_{w-Hog}	d	p_{hd}	40ft heavy container	a_v
7	Empty within one 40 ft bay and hatch covers over the bay; full within other bays and hatch covers (heeling of ship)	—	—	d	—	40ft heavy container	—
8	Full within hold of all holds and on all hatch covers (heeling of ship)	—	—	d	—	20ft heavy container	—
9	Full within hold of all holds and on all hatch covers (longitudinal motions of ship)	$\overline{M}_{s-Sag}$	M_{w-Sag}	d	p_{hd1}	40ft heavy container within holds, 20ft heavy container on hatch covers	a_l, a_v
10	Damage (heeling of ship)	$\overline{M}_{s-Sag}$	—	d_{dam}	—	40ft Heavy container (except the damaged tank in the middle)	—

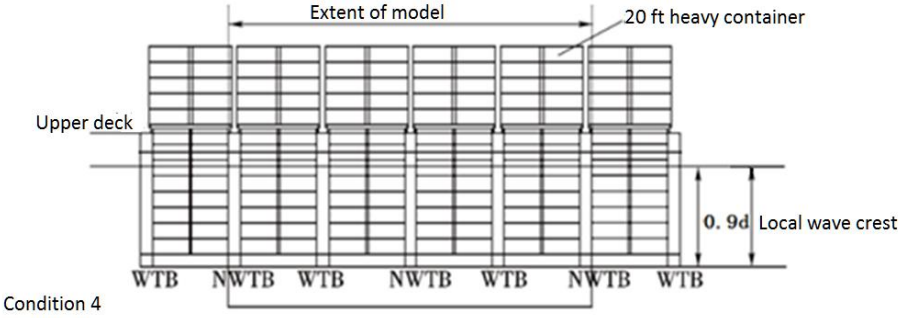
Notes:
(1) d — draught, in m;
(2) Heavy container — the weight of a container is to be taken as permissible stack weight divided by the maximum number of tiers;
(3) Light container — the weight of a container is not to be greater than the values taken as follows:
In hold: 55% of the weight of heavy container;

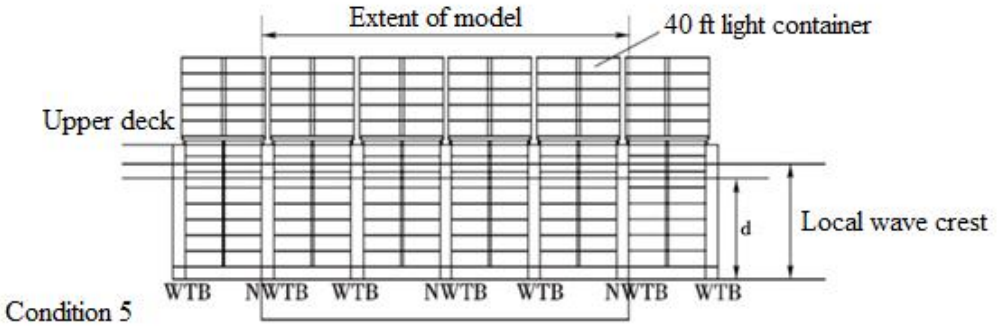
On hatch covers: to be taken as 90% of the permissible stack weight divided by the maximum number of tiers or 17 tons, whichever is the lesser;
(4) for condition 7 and 8, the heeling angle is to be calculated in accordance with Section 5, Chapter 1 of this PART; Where the direct calculation of wave load is available, the heeling angle predicted by direct calculation may be accepted, but not to be less than 18°;
(5) for condition 9, loads within hold and on hatch covers to be determined as specified in 2.4.3 and 2.4.4;
(6) where a hold consists of two or more 40 ft bays, then each bay is to be considered as entirely empty;
(7) definition for d_{dam} is defined in 2.4.5 of this appendix.



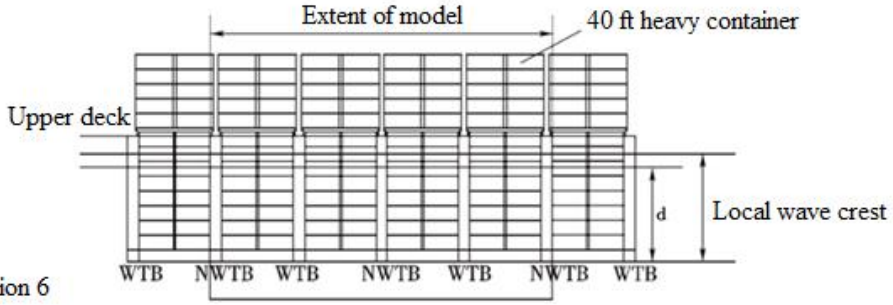




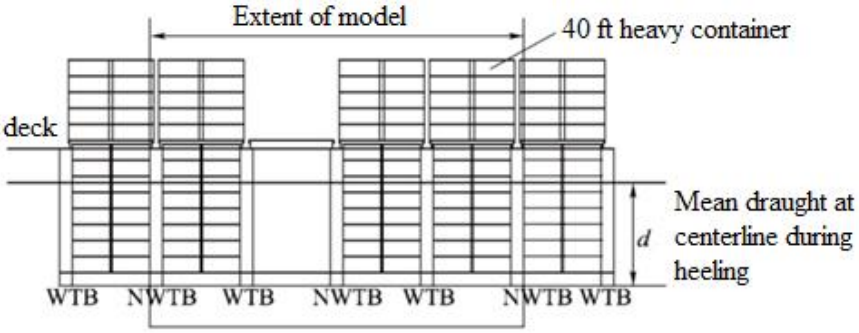




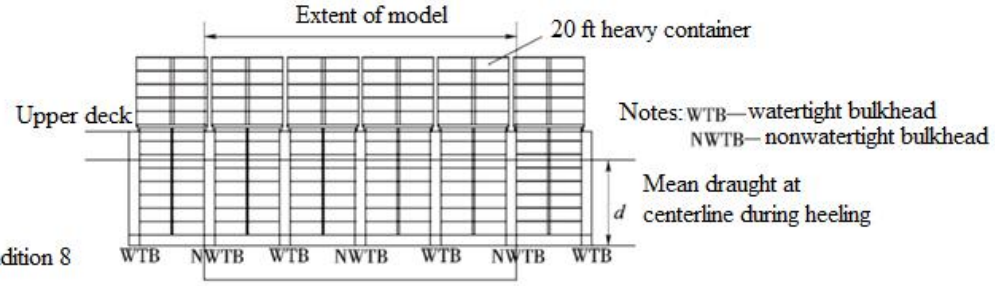
Condition 5



Condition 6



Condition 7



Condition 8

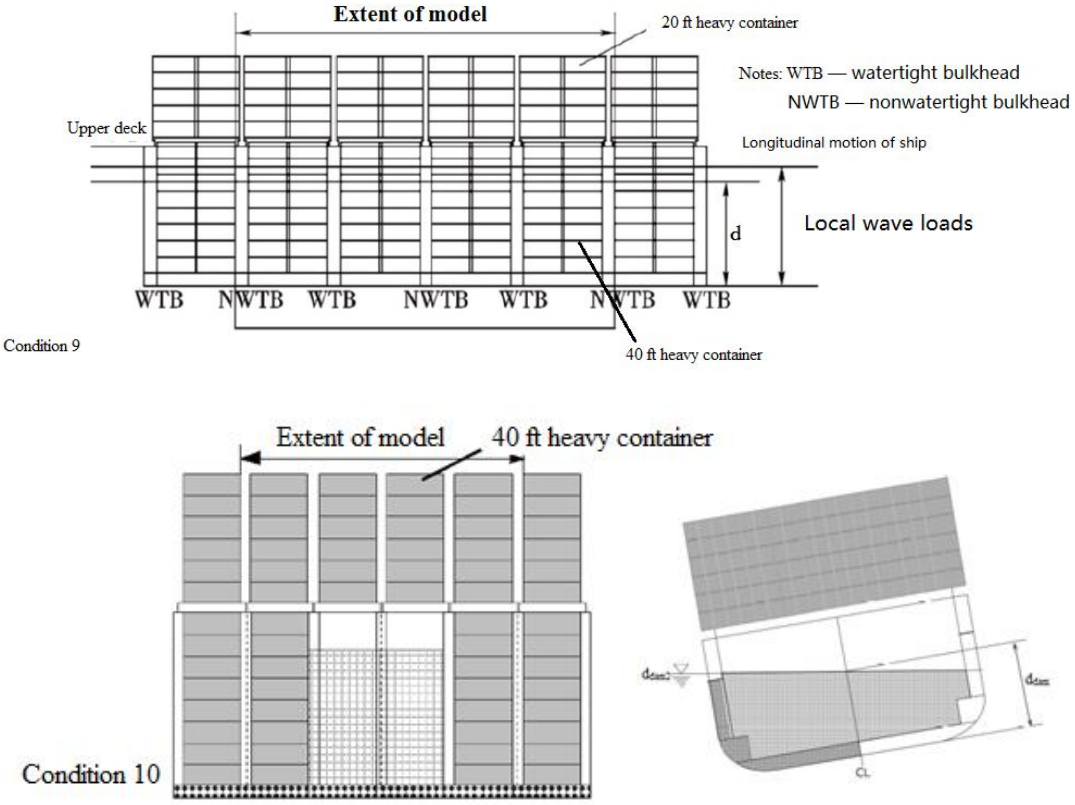


Figure 2.4.1 Loading conditions

2.4.2 For heeling conditions (conditions 7 and 8), the load components are to be calculated assuming that the ship heels to maximum heeling angle. The transverse load components of containers in holds are to act as a group of concentrated forces on transverse bulkheads, with the locations of container corners corresponding to transverse bulkheads as acting points. The load components from containers on deck are to act as a group of horizontally distributed shear forces on nodes of top elements of the transverse coaming.

2.4.3 Where deck is fitted with torsion box girders and the span of the cross deck box is not greater than 13.0 m, the condition 9 need not be considered.

2.4.4 For surging condition (condition 9), the forces arising from acceleration of the longitudinal motion of each container within hold is to be distributed from corresponding corners of the container to primary members of the transverse bulkhead (or the transverse support bulkhead) in way of cell guides. Determination of loads due to containers on hatch covers is as follows:

(1) The longitudinal forces from containers on each hatch cover are to be calculated at mid-height of the stack. The moment about the stack base caused by longitudinal forces may be ignored.

(2) The number of tiers of containers is the maximum one of loaded containers, and the maximum stack weight and the number of tiers are to be those permitted in the loading manual or the cargo handling manual.

(3) The longitudinal forces from containers sited between the ship's side and the longitudinal hatch coamings may be ignored.

(4) 15% of the total longitudinal force acting on hatch covers is to be distributed on nodes at top of longitudinal and transverse hatch coamings to simulate the friction force to which the bearing pads at hatch coamings are subjected due to longitudinal motion.

(5) The remaining 85% of the longitudinal forces on hatch covers are to act on nodes corresponding to the longitudinal stopper positions at one end of the hatch cover (top of the transverse hatch coaming). If the stopper positions are unknown, they are assumed to be located at the mid-breadth of the aft end of the hatch cover. Three covers are to be assumed if the number of hatch covers is unknown.

2.4.5 For damage condition (condition 10), it is assumed that any cargo hold of ship is flooded to the deepest equilibrium waterline. Only the damage of middle hold and the ballast tank on the same side is considered in the FE model. The loads are applied to the container in the same way of that specified in 2.4.2. The maximum height of damage point d_{dam2} and d_{dam} in way of longitudinal centerline is to be determined by the deepest equilibrium waterline.

2.5 Boundary conditions

2.5.1 Boundary conditions for local loads

2.5.1.1 For symmetric loading cases (conditions 1, 2, 3, 4, 5, 6, 9, 10), see Table 2.5.1.1(1) for boundary conditions; for asymmetric loading cases (conditions 7 and 8), see Table 2.5.1.1(2) for boundary conditions; nodes, intersection lines and end planes in the Table are shown in Figure 2.5.1.1.

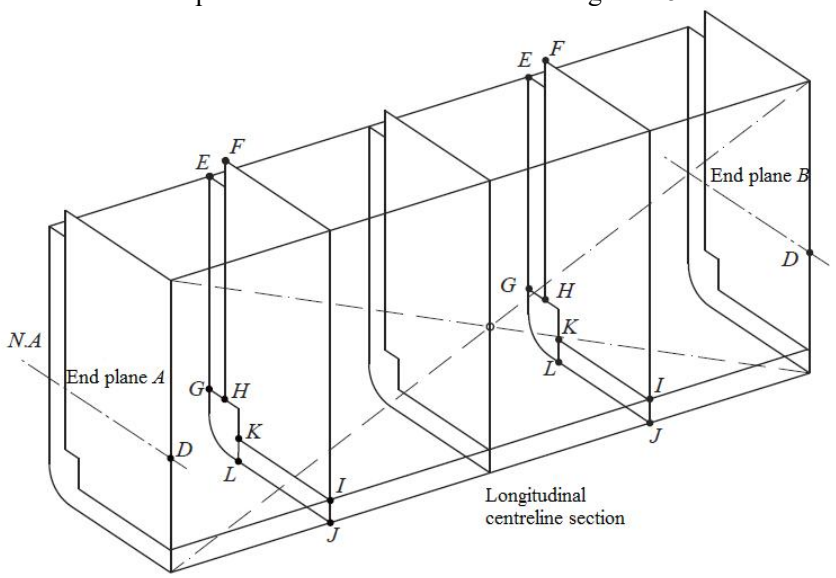

Figure 2.5.1.1 Boundary Conditions

2.5.1.2 For symmetric loading cases, vertical spring elements are to be provided at nodes on intersections of shell plating and inner hull plating with forward and aft transverse bulkheads. For asymmetric loading cases, Horizontal spring elements are to be provided at nodes on intersections of bottom plating and inner bottom plating with forward and aft transverse bulkheads in addition that vertical spring elements are to be provided at nodes on intersections of shell plating and inner hull plating with forward and aft transverse bulkheads. The coefficient of elasticity of spring elements is to be distributed evenly and calculated by the following formula:

$$K = \frac{5GA}{6l_H n} \quad \text{N/mm}$$

where: G — shear modulus of elasticity of material, $G = 0.792\times10^5$ N/mm^2 for steel;

A — shearing area of shell plating, inner hull plating, bottom plating and inner bottom plating in way of forward and aft bulkheads, in mm^2;

l_H — length of midship hold, in mm;

n — number of nodes on vertical intersections of shell plating and inner hull plating or number of nodes on horizontal intersections of bottom plating and inner bottom plating.

Boundary Conditions for Symmetric Loading Cases Table 2.5.1.1(1)

Position	Displacement constraint			Rotation constraint		
	δ_x	δ_y	δ_z	θ_x	θ_y	θ_z
Node *J*	—	Constraint	—	—	—	—
End planes *A*, *B*	Constraint	—	—	—	Constraint	Constraint

End planes A, B	Constraint	—	—	—	Constraint	Constraint
Intersection lines EG, FH	—	—	Spring	—	—	—
Intersection lines IK, JL	—	Spring	—	—	—	—

2.5.2 Boundary conditions for global loads

2.5.2.1 See Table 2.5.2.1 for boundary conditions for global loads. The boundary conditions apply to the calculation of hull girder bending moments for Table 2.4.1 only.

2.5.2.2 An independent point *D* (see Figure 2.5.1.1) is to be set in way of intersection of the neutral axis with the longitudinal centerline section within end planes *A* and *B*, the overall longitudinal bending moment is to be applied on the point *D*, and the degree of freedom δ_x, δ_y and δ_z of each member node for end planes is linked to the independent point.

2.5.2.3 The displacements of the independent point *D* within end planes *A* and *B* in transverse direction, vertical direction, and the rotation around longitudinal axes are restrained, i.e.: $\delta_y = \delta_z = \theta_x = 0$; the displacement of the independent point *D* within end plane *A* in longitudinal direction is restrained, i.e.: $\delta_x = 0$.

Boundary conditions for global loads **Table 2.5.2.1**

Independent point D (End plane B)	—	Constraint	Constraint	Constraint	Bending moment	—

2.6 Strength evaluation

2.6.1 Evaluation area

2.6.1.1 Evaluation is to be carried out for middle hold and the primary members with the scope of a transverse framing extending forward and afterward.

2.6.2 Yield strength evaluation

2.6.2.1 The strength check is to be carried out after the stresses due to local load case and global load case are combined. The in-plane stress of the element is to be taken for stress of plate element.

2.6.2.2 In all conditions, permissible stresses of primary members are shown in Table 2.6.2.2.

Permissible Stresses **Table 2.6.2.2**

Structural member	Loading condition	Permissible stress (N/mm^2)	
		$[\sigma_e]$	$[\tau]$
Deck plating	LC1, 2, 3, 4, 5, 6, 9	225/*K*	—
Bottom plate, inner bottom plate	LC1, 2, 3, 4, 5, 6, 9	225/*K*	—
Shell plating, longitudinal bulkhead	LC1, 2, 3, 4, 5, 6, 9	225/*K*	115/*K*
Bottom girders	LC1, 2, 3, 4, 5, 6, 9	235/*K*	115/*K*
Double bottom floors	LC1, 2, 3, 4, 5, 6, 7, 8, 9	175/*K*	90/*K*
Transverse web frames	LC1, 2, 3, 4, 5, 6, 7, 8, 9	195/*K*	95/*K*
Longitudinal stringers	LC1, 2, 3, 4, 5, 6, 9	225/*K*	—
	LC 7, 8	175/*K*	90/*K*
Transverse bulkhead plating	LC1, 2, 3, 4, 5, 6, 9	180/*K*	100/*K*
	LC10	235/*K*	—
Transverse bulkhead webs	LC1, 2, 3, 4, 5, 6, 7, 8, 9	175/*K*	—
	LC10	235/*K*	—
Connection of the double bottom and side platform to the watertight transverse bulkhead structure	LC10	235/*K*	—
Cross-deck torsion box	LC 7, 8	175/*K*	90/*K*
	LC9	175/*K*	—

Structural member	Loading condition	Permissible stress (N/mm^2)	
		$[\sigma_e]$	$[\tau]$
	LC10	235/K	—
Bracket toe end with local stress concentration	LC1, 2, 3, 4, 5, 6, 7, 8, 9, 10	220/K	—

Notes:
(1) K— material factor;
(2) The elements at king-pin area of hatch coaming are directly subjected to the load resulting from hatch cover under loading condition 9, so the permissible equivalent stress is $[\sigma_e]$=195/K N/mm^2.

2.6.3 Buckling strength evaluation

2.6.3.1 Finite element buckling strength evaluation is to be carried out for members such as shell plating, inner bottom plating, deck, bulkhead plating of hull structure of containership, web plates and pillars of primary and local supporting members, horizontal/vertical girders of supporting bulkhead.

2.6.3.2 See 2.6.1 for evaluation area.

2.6.3.3 In addition to the requirements of 2.6.3.4 to 2.6.3.8, buckling strength evaluation is to be carried out in accordance with the requirements for finite element buckling as specified in Chapter 8 of PART 9-1 of the Rules.

2.6.3.4 In buckling strength evaluation, the calculation of the buckling capacity of all panels and stiffeners is to be carried out based on the size after deduction of the standard thickness deduction t_r. The standard thickness deduction t_r is shown in Table 2.6.3.4.

Standard Thickness Deduction **Table 2.6.3.4**

Position	Standard thickness deduction (mm)
Deck, wing space plating (e.g. second deck, etc.)	1.0
Longitudinal bulkhead (inner hull plating)	1.0
Shell plating (including bottom plating), inner bottom	1.0
Inner structure (girder, floor) of double bottom and wing space	1.0
Transverse bulkhead structure (watertight, non-watertight)	0
Cross-deck torsion box	0

Note: If other thickness deduction method is used for buckling strength evaluation (e.g. based on corrosion allowance), the permissible utilization factor is to be considered otherwise.

2.6.3.5 For stresses obtained by calculation of finite element model (including stress components of direct stress and shear stress), if stress component is local stress or including components of local stress, the correction of stress is to be carried out for the stress calculation according to the following formula:

$$\sigma_A = \frac{\sigma t}{t - t_r} \qquad \text{N/mm}^2$$

where: σ_A — corrected buckling working stress (including components of axial compressive stress and shear stress), in N/mm^2;

σ — stress obtained by finite element calculation ((including components of axial compressive stress and shear stress), in N/mm^2;

t — plate thickness for finite element calculation, in mm;

t_r —standard thickness deduction, in mm, see Table 2.6.3.4.

2.6.3.6 For permissible buckling utilization factor η_{all} used for buckling strength evaluation, see Table 2.6.3.6.

Permissible buckling utilization factor η_{all} **Table 2.6.3.6**

Structural component	Permissible buckling utilization factor η_{all}
— Plating(including web plates in way of opening） — stiffener — stiffened panel	1.00
— strut, pillar — horizontal/vertical girder of supporting bulkhead checked by strut buckling mode	0.75

Structural component	Permissible buckling utilization factor η_{all}
— collision bulkhead (where necessary)	0.90

2.6.3.7 Definition of method for evaluating the stiffened/unstiffened panels of hull panel of containership is shown in Table 2.6.3.7 and Figures 2.6.3.7(1) to 2.6.3.7(6).

Types of panels and corresponding evaluation methods Table 2.6.3.7

Structural element	Evaluation method	Definition for regular panel
Longitudinal structure , see Figures 2.6.3.7(1), (4), (6)		
external shell plate (bottom plating, side shell plating） inner bottom plating inner hull/longitudinal bulkhead plating horizontal and longitudinal stringer of hopper tank and vertical side plating	SP-A	Length: between web frames Width: between primary supporting members (PSM)
Hatch coaming side plating	SP-A or UP-A	Length: between web frames Width: between primary supporting members (PSM)
Upper deck	SP-B[5]	Length: between web frames Width: between primary supporting members (PSM)
Double bottom longitudinal girders	SP-B[5]	Length: between web frames Width: height of the whole web plate
Transverse structure, see Figure 2.6.3.8(2)		
Transverse framing of deck/web plate of cross-deck torsion box, including bracket of regular mesh shape	SP-A[6]	Local stiffener / between face plate/PSM
Transverse framing of deck/ web plate of cross-deck torsion box, including bracket of irregular mesh shape	SP-B[5]	Local stiffener /between face plate/PSM
Transverse webs of double hull wing tank	SP-B[5]	Length: height of the whole web plate Width: between primary supporting members
Transverse webs of double hull wing tank (independent arrangement)	SP-B	Length: height of the whole web plate Width: between primary supporting members
Irregular stiffened panel, such as web plate panel in hopper tank and at bilge (continuous alignment arrangement)	UP-A	Local stiffener / between face plate/PSM
Irregular stiffened panel, such as web plate panel in hopper tank and at bilge (incontinuous alignment arrangement)	UP-B[5]	Local stiffener / between face plate/PSM
Double bottom floors	SP-A[6]	Length: height of the whole web plate Width: between primary supporting members
Watertight transverse bulkhead and transverse supporting bulkhead, see Figure 2.6.3.8(3),(4),(5)		
All regular bulkhead stiffened panels, including secondary buckling stiffeners vertical to the regular stiffeners (e.g. carling)	SP-A	Length: between primary supporting members Width: between primary supporting members
All irregular bulkhead stiffened panels, such as web plate panels in hopper tank and at bilge	UP-A	Local stiffener / between face plates
Bulkhead horizontal web plate, including bracket of regular mesh shape (three arrangement of panel and over)	SP-B[5]	Local stiffener / between face plates
Bulkhead horizontal web plate, including bracket of regular mesh shape (two arrangement of panel and less)	SP-B [5]	Local stiffener / between face plates
Bulkhead horizontal web plate, including bracket of irregular mesh shape	UP-B	Local stiffener / between face plates
Bulkhead vertical web plate, including bracket of regular mesh shape	SP-B [5]	Local stiffener / between face plates
Bulkhead vertical web plate, including bracket of irregular mesh shape	UP-B	Local stiffener / between face plates
Cross deck, see Figure 2.6.3.8(6)		
Longitudinal deck strips between hatchways	SP-B[5]	Local stiffener / between PSM
Cross deck strips between hatchways	SP-B	Local stiffener / between PSM
Notes: ① SP means stiffened panel;		

Structural element	Evaluation method	Definition for regular panel
② UP means unstiffened panel; ③ A means method A; ④ B means method B; ⑤ For a long side of the web plate panel of primary supporting member, if alongside the face plate, or alongside the attached plate without the property of "in-line support", e.g. property of "pull-in", method B (SP-B or UP-B) is to be selected. For other situations, method A (SP-A or UP-A) is to be selected. ⑥ In typical case that the short edge and sheathing (flange of attached plate) are connected with each other, method A (SP-A or UP-A) is to be selected. However, if a long side of the panel is without the property of "in-line support" and may be pulled in, method B (SP-B or UP-B) is to be selected. ⑦ In-line support means an edge of panel (always) subject to the structural support or restraint of adjacent panel and/or edge stiffener. ⑧ Pull-in means an edge of panel may be pulled freely toward the center of the plate. In this Table, "in-line support" and "pull-in" represent opposite mechanical properties.		

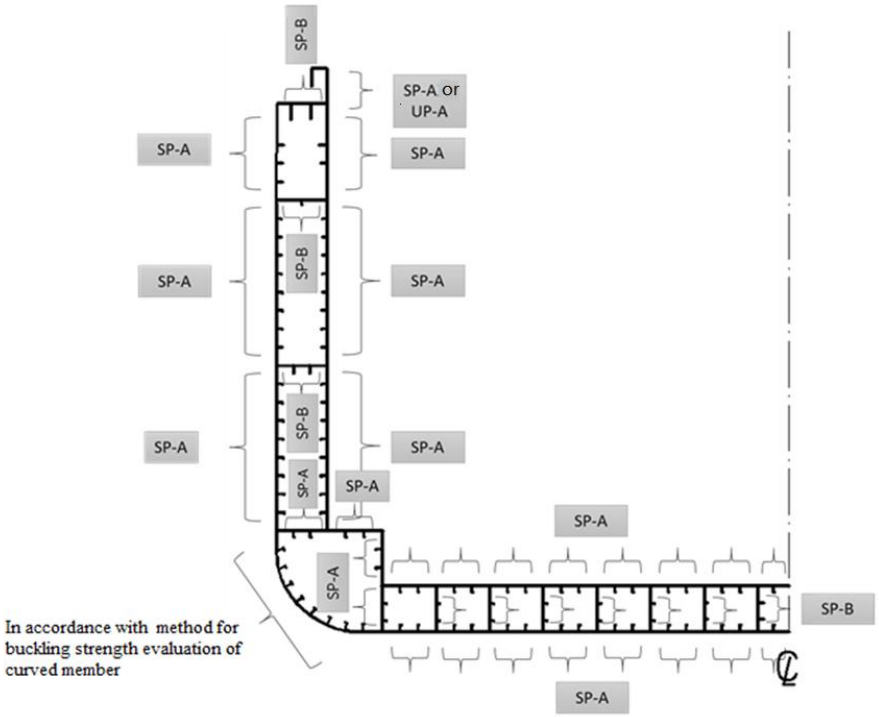

Figure 2.6.3.7(1) Typical longitudinal panels of containership

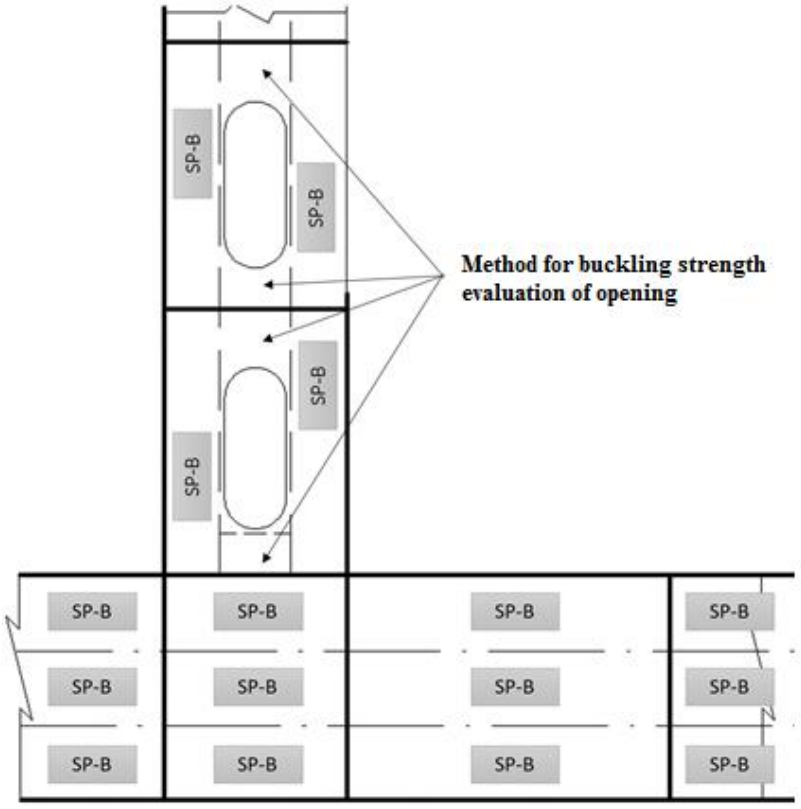

Figure 2.6.3.7(4) Transverse bulkhead vertical girder and double bottom girders

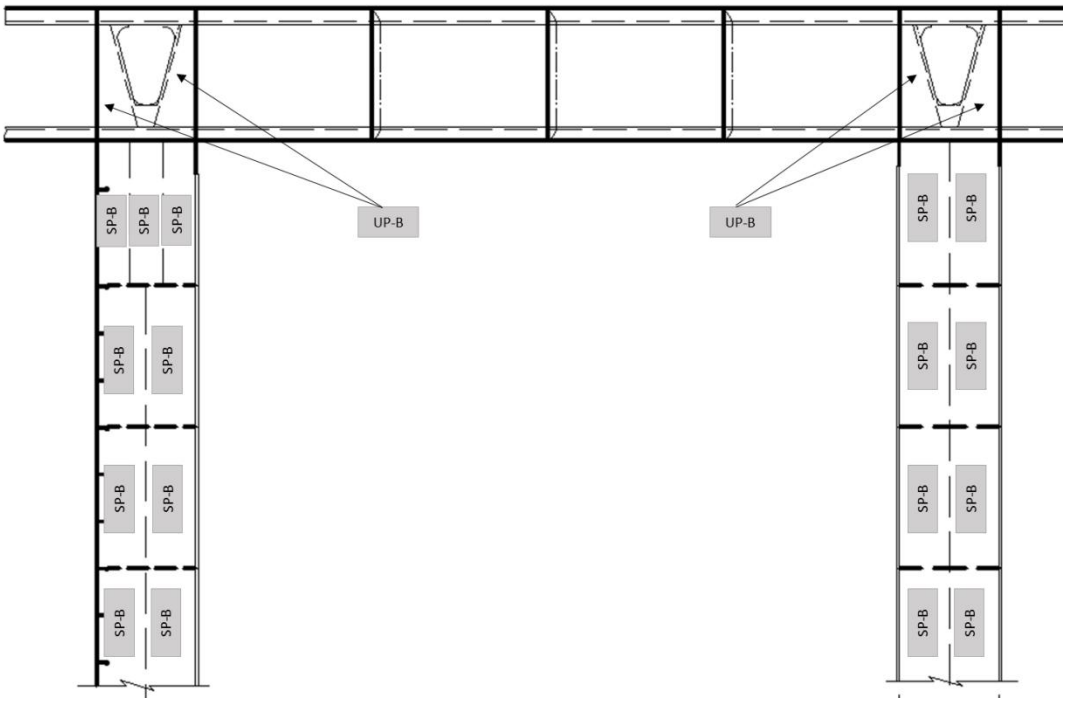

Figure 2.6.3.7(5) Horizontal girder of transverse bulkhead

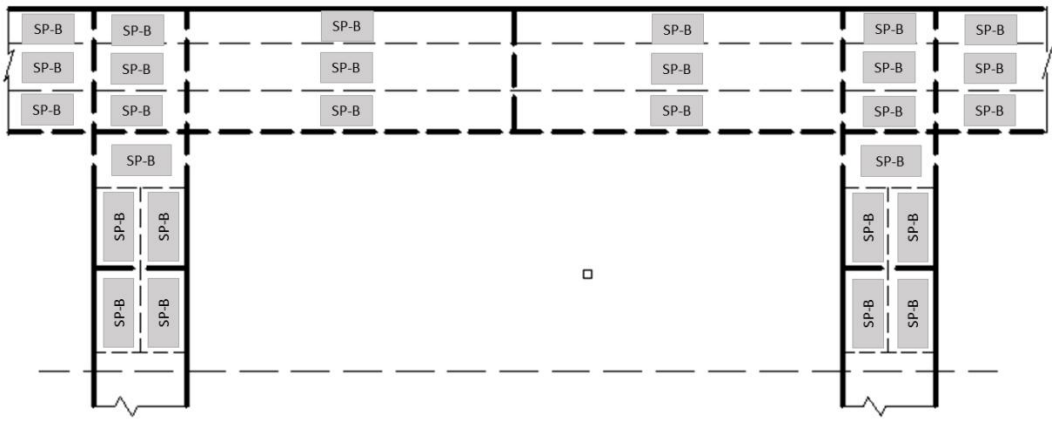

Figure 2.6.3.7(6) Deck strips between hatchways

2.6.3.8 For vertical and horizontal webs of supporting bulkhead, see Figure 2.6.3.8, the buckling utilization factor of its members is to be taken as the greater of the maximum buckling utilization factor of web plate panel (stiffened/unstiffened panel) and the maximum buckling utilization factor of pillars of web.

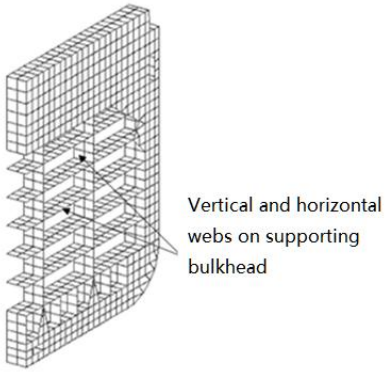

Figure 2.6.3.8 Vertical and horizontal webs on supporting bulkhead

2.7 Fine mesh analysis

2.7.1 In order to evaluate more accurately the stress level and distribution in way of the concentration of local structural stresses, fine mesh analysis and strength evaluation are at least to be carried out to the following critical parts in the evaluation area required by 2.6.1:
(1) in way of the steps of transverse web frames in the middle of supporting bulkhead and watertight transverse bulkhead (for cargo hold with two supporting transverse bulkheads, the location is the middle of the two supporting transverse bulkheads), see Figure 2.7.1(1).
(2) connection of bottom girder to inner bottom plate and bottom plating in watertight transverse bulkhead area, see Figure 2.7.1(2).
(3) large bracket toe near steps of the supporting bulkhead, see Figure 2.7.1(3).
Fine mesh analysis is also to be carried out if the stress in other critical areas exceeds the permissible criteria.

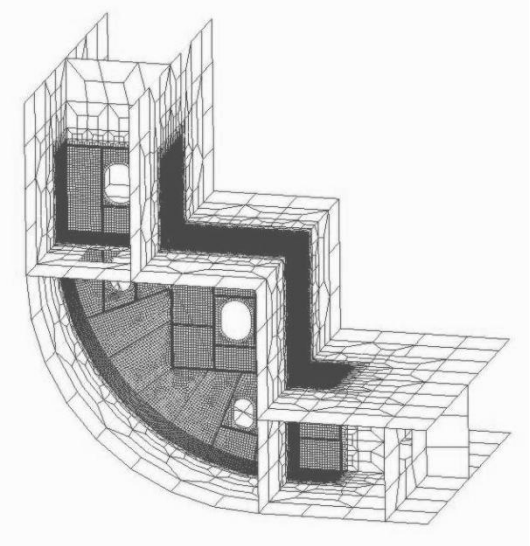

Figure 2.7.1(1) Refined transverse web frame

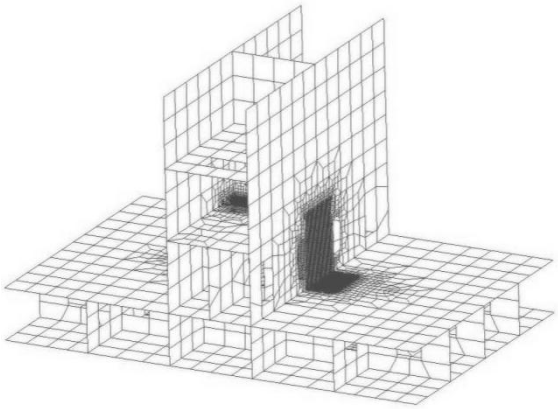

Figure 2.7.1(2) Refined structural connection of girder to inner bottom plating and bottom plating

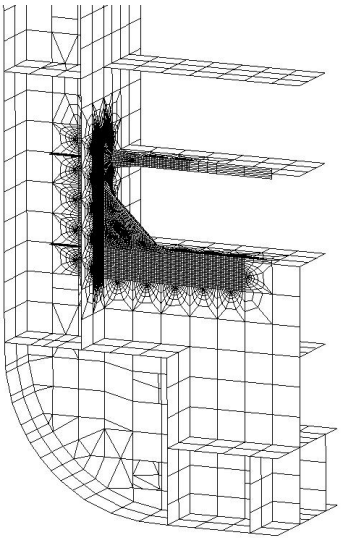

Figure 2.7.1(3) Refined large bracket toe of supporting bulkhead

2.7.2 The fine mesh analysis may be conducted by sub-modeling method and embedding method. The individual local finite element model in fine mesh areas is to be used for sub-modeling method, of which the boundary conditions and loads may be obtained from the finite element model of cargo hold blocks. The embedding method is to carry out analysis by embedding the fine mesh model into the finite element model of cargo hold block.

2.7.3 Where the local finite element model is used, its range is to be such that the stress of critical locations is not significantly affected by boundary conditions and applied loads. The boundaries of refined model are to be in consistent with the main support members (e.g. girders and floors) of finite element model o cargo hold blocks.

2.7.4 The mesh size of fine mesh area is not to be greater than 50 mm ×50 mm. In general, the range of fine mesh area is not to be less than 10 elements in all directions of critical positions.

2.7.5 Plate element simulation is to be used for all plating and stiffeners within fine mesh areas. The transition of mesh density is to be maintained stable. The aspect ratio of elements within fine mesh area is to be close to 1 as far as possible so as to avoid the change of mesh density and use of triangular element, as well as the distortion element of which the angle is less than 60° or greater than 120°. In any case, the aspect ratio of element is not to exceed 3. The stiffeners beyond the fine mesh area may be simulated by beam element.

2.7.6 For the transverse web frames, if finite element sub-model method is used, the longitudinal range of model is at least to be of the spacing of "1+1" web frames, i.e., one web frame spacing is extended both before and after the checked transverse web frames, and the web frames at forward and after ends may not be modeled. In addition, the model is to include the full molded breadth and full molded depth of ship.

2.7.7 The fine mesh analysis is to be carried out in accordance with the design conditions specified in this Appendix.

2.7.8 Where sub-model method is used for fine mesh analysis, node displacement obtained from finite element model calculation for cargo hold block is to be applied to the corresponding boundary node of individual local finite element model as a given displacement.

2.7.9 The stress criteria and check method for fine mesh analysis are shown in Table 2.7.9.

Maximum permissible membrane stress of fine mesh analysis Table 2.7.9

Element stress	Yield utilization factor (applicable to all conditions)
Element not adjacent to welds	$\lambda_y \leq 1.7$
Element adjacent to welds	$\lambda_y \leq 1.5$

where: (1) λ_y — yield utilization factor;

$$\lambda_y = \frac{\sigma_e}{[\sigma_e]}$$

(2) In the block finite element model, if the Von Mises stress of element located in the fine mesh check area exceeds the permissible values given in Table 2.7.9, the mean value of Von Mises stress calculation results obtained from fine mesh analysis with the area equivalent to the mesh size of block finite element model is not to exceed the permissible value specified in Table 2.7.9.

(3) The maximum permissible stress is to be based on the mesh size of 50 mm ×50 mm. If smaller size is used, the element mean Von Mises stress on the equivalent areas of above-mentioned mesh size may be compared with the permissible stress. The mean stress is to be calculated only when all the boundaries of element are within the range of above-mentioned mesh size.

Von Mises mean stress is to be weighted based on element area:

$$\sigma_{e-av} = \frac{\sum_1^n A_i \sigma_{e-i}}{\sum_1^n A_i}$$

Where: σ_{e-av} — Von Mises mean stress;

σ_{e-i} — Von Mises stress of the ith plate element within the area to be considered;

A_i — area of the ith plate element within the area to be considered;

n — number of elements within the area to be considered.

Note 1: The mean stress calculation is to be based on the stress at centroid of the element, and the value is not to be obtained by interpolation and/or extrapolation.

Note 2: Stress averaging method is not allowed to be used for evaluation in way of structural discontinuities and abutting members.

2.8 Strength evaluation of fuel oil tank areas

2.8.1 Where fuel oil tanks are provided within the cargo hold areas of container ships, structural strength evaluation is to be carried out for the primary members in the fuel oil tank areas:

(1) boundary structures of fuel oil tanks;

(2) deck and cross deck within fuel oil tank areas;

(3) internal grillage structures of fuel oil tanks, i.e., girders and web frame structures;

(4) double bottom structures below fuel oil tanks (bottom plating, inner bottom plating, girders and floors);

(5) side structures in way of fuel oil tank (side shell plating, inner shell plating, longitudinal stringers, side web frames).

2.8.2 Structural modeling

2.8.2.1 The longitudinal extent of block model is generally to cover the complete structures within the fuel oil tank area, with a cargo hold structure of 40 ft container bay extended both forward and afterward, i.e., “one 40 ft container bay + fuel oil tank + one 40 ft container bay”. The typical finite element model is shown in Figure 2.8.2.1.

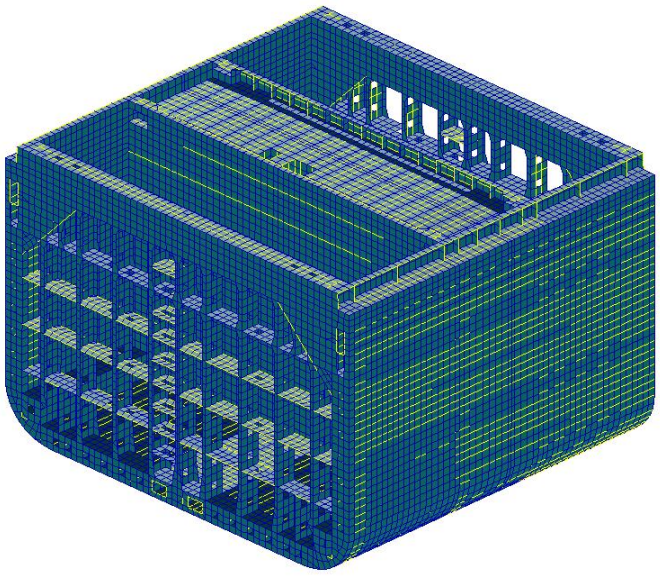

Figure 2.8.2.1 Finite Element Model of Fuel oil tank

2.8.2.2 Except the above-mentioned modelling requirements, the other structural modeling requirements are listed in 2.2 of this Appendix.

2.8.3 Design loads

2.8.3.1 Except the liquid pressure of tanks, the other loads are given in 2.3 of this Appendix.

2.8.3.2 Pressures of liquid in tank

The pressures of liquid in tank include the pressure in static load condition and the pressure in dynamic load condition.

(1) The pressure of ballast tanks under dynamic load condition p_{blast1} and the pressure of fuel oil tank under dynamic load condition p_{HD1} are to be calculated by:

$$p_{blast1} = \rho_w (a_v + g) h_1 + 10 p_v \quad \text{kN/m}^2$$

$$p_{HD1} = \rho_f (a_v + g) h_1 + 10 p_v \quad \text{kN/m}^2$$

where:

h_1 — distance from the load point to the top of tank, in m;

ρ_w — density of sea water, in 1.025 t/m^3;

ρ_f — density of oil fuel, in 1.0 t/m^3;

p_v — dynamic load coefficient, to be taken not less than 0, is to be calculated by:

$$p_v = \Delta z - 1.5$$

where: ΔZ — distance between the top of tank and the top of overflow pipe, in m.

(2) The pressure of ballast tanks under static load condition p_{blast} and The pressure of fuel oil tanks under static load condition p_{HO} are to be calculated by:

$$p_{blast} = \rho_w g h_2 \quad \text{kN/m}^2$$

$$p_{HO} = \rho_f g h_2 \quad \text{kN/m}^2$$

Where: h_2 — distance from the load point to the top of overflow pipe, in m.

ρ_w , ρ_f — the same as 2.8.3.2(1).

2.8.4 Loading conditions

2.8.4.1 In order to fully evaluate the structures of fuel oil tanks, the loading conditions are to be determined according to the arrangement type of fuel oil tanks. The basic principle is that strength analysis

is to be carried out for the structures within fuel oil tank area based on full load of fuel oil tank, alternate load and light ship conditions respectively. Figure 2.8.4.1 gives several typical arrangement types of fuel oil tanks, and the loading conditions of various typical fuel oil tank arrangement types are shown in Table 2.8.4.1(1) to Table 2.8.4.1(3).

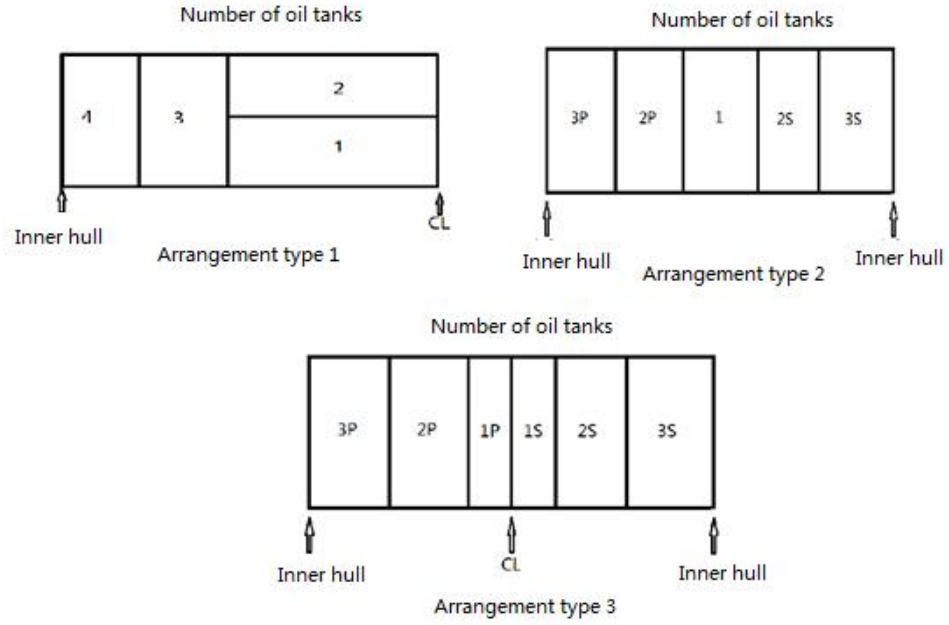

Figure 2.8.4.1 Diagram of Typical Fuel Oil Tank Arrangement Types (Vertical View)

Loading condition of Typical Fuel Oil Tank Arrangement Type 1 Table 2.8.4.1(1)

2.8.5 Boundary conditions

2.8.5.1 The boundary conditions are to be in accordance with the relevant provisions of 2.5 in this Appendix.

2.8.6 Strength evaluation

2.8.6.1 Evaluated areas

2.8.6.1 The mid tank and primary structural members within the extent of one web frame extending forward and afterward are to be evaluated.

2.8.6.2 Yield strength evaluation

(1) The stresses generated by local load case and global load case are to be combined for strength check. The equivalent stress at midpoint of element is to be taken as the plate element stress.

(2) The permissible stress for each primary structural member is given in Table 2.8.6.2.

Permissible stress Table 2.8.6.2

Structural member	Permissible stress (N/mm^2)	
	$[\sigma_e]$	$[\tau]$
Bottom plating, inner bottom plating	225/K	–
Side shell plating, inner hull longitudinal bulkhead	225/K	115/K
Bottom girder	235/K	115/K
Intersection of oil fuel boundaries and bottom girders	235/K	115/K
Double bottom floor	175/*K*	90/*K*
Transverse web frame	195/*K*	95/*K*
Fuel oil tank bulkhead (excluding inner hull longitudinal bulkhead)	180/K	100/K
Stringers in fuel oil tank and girder webs between bulkheads	195/K	100/K

Note: *K*— material factor.

2.8.6.3 Buckling strength evaluation

(1) The buckling strength evaluation method is given in the provisions of 2.6 in this Appendix.

2.8.6.4 Fine mesh analysis

(1) If the yield stress exceeds the permissible criteria, fine mesh analysis may be carried out in the critical areas, such as the connection of fuel oil tank boundaries to bottom girders, platform corners within fuel oil tanks, etc. The fine mesh analysis method, element requirements and evaluation criteria are given in 2.7 of this Appendix.

3 Direct Calculation of Global Strength of Ship

3.1 General requirements

3.1.1 Direct strength calculation of whole ship is to be used to evaluate the global strength of primary hull members under combined bending and torsional moments. In calculation, the following two methods may be used:

Method 1: Analysis where hull girder loads (vertical bending moment, horizontal bending moment and torsional moment) are directly applied to the full ship finite element model.

Method 2: Analysis where direct loads transferred from wave load analysis are applied to the full ship finite element model.

3.2 Loading conditions

3.2.1 Still water condition

3.2.1.1 The still water condition is to be selected according to the loading manual, and generally the full load condition where maximum still water bending moment occurs and normal ballast condition where

maximum GM occurs are to be taken.

3.2.1.2 Under the maximum still water bending moment conditions, the ship is to be in or close to upright condition, at or near to the draught d, and the still water bending moment within $0.4L$ amidships is the maximum value. If one 40 ft bay in midship range is to be left empty, the maximum still water bending moment condition under this loading condition is required.

3.2.1.3 Consideration is also to be taken if more severe non-homogeneous loading conditions exist in the loading manual.

3.2.2 Wave load condition

3.2.2.1 The still water load condition as determined according to 3.2.1 is taken as the basic loading condition for wave load conditions.

3.2.2.2 Unless specified otherwise in the Appendix, the parameters of wave load conditions, such as length, height and phase of waves, are to be determined by the method and procedure used for equivalent design wave, see Section 5, Chapter 1 of this PART. The wave load conditions are to include head sea,oblique sea and beam sea conditions.

3.2.2.3 The dominant load parameters for direct calculation of wave loads include vertical wave bending moment, horizontal wave bending moment, torsional moment, acceleration and rolling angle. The prediction of the maximum wave load likely to be experienced during the service life covers mainly sea conditions to be encountered during navigation in sea areas around the world, expressed in the probability of waves occurring in various periods and heights. It is suggested that the wave scatter diagram recommended by IACS be adopted. The probability level of dominant load parameters is generally taken as 10^{-8}, and that of the prediction value of maximum vertical wave bending moment corresponding to the value as required in Section 2 of this Chapter may also be taken.

3.2.3 Loading conditions

3.2.3.1 Each calculation condition is based on different combination of still water condition and wave load condition. Generally, the global strength analysis of container ships is to be checked in accordance with the loading conditions in Table 3.2.3.1. For two-island container ship, the considered condition of the maximum torque at fore and aft ends of the fore island is also to be checked.

Loading Conditions **Table 3.2.3.1**

Loading conditions / Dominant load parameters	homogeneous full load	Normal ballast	Non-homogeneous loading（if any）
Maximum vertical wave bending moment	Applicable	Applicable	Applicable
Maximum horizontal wave bending moment	Applicable	Applicable	Applicable
Maximum torque in way of $L/2$	Applicable	Applicable	Applicable
Maximum torque in way of $L/4$	Applicable	Applicable	Applicable
Maximum torque in way of $3L/4$	Applicable	Applicable	Applicable
Maximum vertical bow acceleration	Applicable	Applicable	Applicable
Maximum rolling angle	-	Applicable	-

3.3 Finite element model for whole ship

3.3.1 Extent of finite element model

3.3.1.1 The ship's global three-dimensional finite element model covers all longitudinal stressed members in main hull within ship's complete length and full breadth, such as deck structure, side and longitudinal bulkhead structure and double bottom structure. The model covers also primary transverse structures such as transverse bulkhead, transverse web frame, transverse deck strip, etc. Local supporting members such as brackets may be omitted in the model. Requirements for openings of web plates of primary structural members are defined in Section 5, Chapter 1 of this PART and openings in brackets may be omitted. A global structural FE model of a typical container ship is shown in Figure 3.3.1.1.

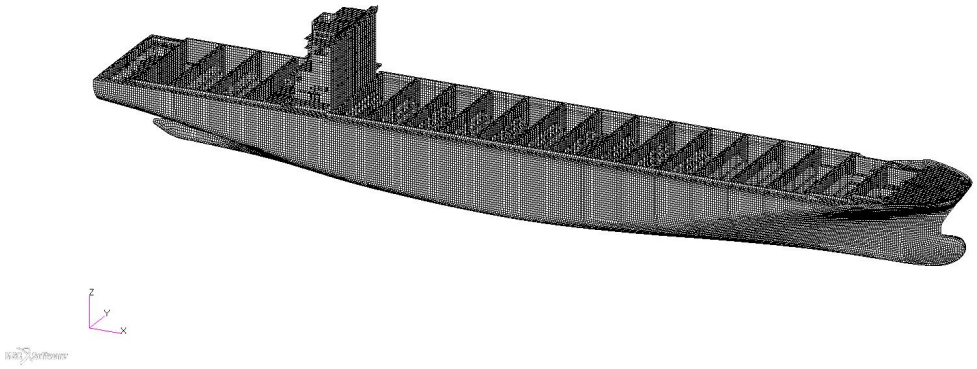

Figure 3.3.1.1 Global Structural FE Model of a Typical Container Ship

3.3.2 Selection of elements

3.3.2.1 All kinds of structures in the model are discretized into the following types of elements based on their structural responses:

(1) Shell element (four-node and three-node elements): such as deck, side shell, bottom plating, inner bottom plating, longitudinal and transverse bulkheads, bottom girder, floor, wing space horizontal girder, transverse web frame, etc.

(2) Beam element: such as girder, beam and watertight bulkhead stiffener, etc.

(3) Rod element: such as pillar, etc.

3.3.3 Meshing

3.3.3.1 Unless otherwise specified in this Appendix, the requirements for structural modeling are given in Section 5, Chapter 1 of this PART.

3.3.3.2 The aspect ratio of elements amidships is not to exceed 1:3 and is not to exceed 1:2 elsewhere. Warped quadrilateral elements are to be avoided for meshing.

3.3.4 Boundary conditions

3.3.4.1 In order to prevent rigid displacements, suitable linear displacement constraints are to be applied at corresponding nodes of hull as shown in Figure 3.3.4.1.

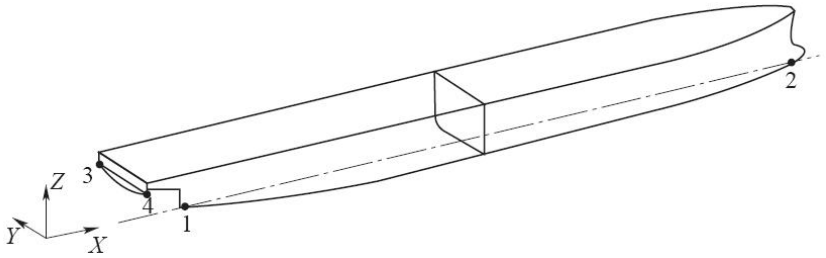

Figure 3.3.4.1 Diagram of Boundary Conditions

3.3.4.2 The displacement in transverse direction for bottom plate keel (in longitudinal centerline section) at aft end (node 1 in Figure 3.3.4.1 of this Appendix) is restrained, i.e.: $\delta_y = 0$; the displacements in longitudinal, transverse and vertical directions for bottom plate keel (in longitudinal centreline section) at fore end (node 2 in Figure 3.3.4.1 of this Appendix) are restrained, i.e.: $\delta_x = \delta_y = \delta_z = 0$.

3.3.4.3 The displacements in vertical direction for node 3 (port) and node 4 (starboard) respectively which are at an equal distance from the longitudinal centerline section on horizontal girder of stern transom plate are restrained, i.e.: $\delta_z = 0$.

3.3.5 Fine mesh analysis

3.3.5.1 Fine mesh analysis is to be carried out if the result of whole ship FE calculation of stresses in the following areas exceeds 90% of the permissible stress specified in 3.4.1 of this Appendix:

(1) in way of the steps of transverse web frames in cargo hold area;

(2) connection of double bottom girder and transverse bulkhead;

(3) face plate of horizontal girders and large bracket toe in way of the supporting transverse bulkhead;

(4) in way of the bracket toe of longitudinal hatch coaming;

(5) in way of hatch corners of hatch coamings top plates and deck plates;

(6) openings on inner shell, hatch coaming, deck and vertical girder and horizontal girder of transverse bulkheads.

3.3.5.2 Fine mesh analysis is to comply with the requirements of 2.7 of this Appendix.

3.4 Yield strength evaluation for global finite element structure of ship

3.4.1 The allowable stress of plates including girder web is as follows:

$$[\sigma_e] = 220/K \quad \text{N/mm}^2$$

where: K — material factor.

3.4.2 The beam element is taken as the axial stress and its allowable stress is as follows:

$$[\sigma] = 220/K \quad \text{N/mm}^2$$

where: K — material factor.

3.4.3 The stress criteria and checking method for fine mesh analysis are defined in 2.7.9 of this Appendix and $[\sigma_e]$ is to be calculated according to 3.4.1.

3.5 Buckling strength evaluation for global finite element structure of ship

3.5.1 The buckling strength evaluation for global finite element structure of ship is to be checked in accordance with 2.6.3 of this Appendix.

4 Fatigue Strength Evaluation

4.1 General requirements

4.1.1 This Section provides methods to evaluate fatigue strength of key positions of container ships under bending and torsional loads.

4.1.2 The wave load calculation for evaluation of fatigue strength of hatch corners is to be based on the equivalent design wave method used for structural analysis of the whole ship, as shown in Section 5 of Chapter 1.

4.1.3 Fatigue damage calculation is based on Palmgren-Miner linear cumulative damage principle, taking into account S-N curves and sea state parameters etc.

4.1.4 In addition to the evaluation method given in this Section, the fatigue evaluation may also be carried out in accordance with relevant requirements of CCS Guidelines for Spectrum-based Fatigue Assessment of Hull Structure.

4.1.5 Hull structures in way of key positions are to be screened based on the result of coarse mesh calculation to determine the fatigue evaluation spots. The evaluation spots are at least to include end bracket toes of longitudinal hatch coaming, hatch corners at the fore (aft) end of engine room, hatch corners at the end of No.1 cargo hold towards the fore end of the ship and a cargo hold hatch corner amidships.

4.2 Loads

4.2.1 The loads for fatigue evaluation are to be obtained from the corresponding loading conditions for global analysis of the ship.

4.2.2 The loading condition is to be taken as the full load condition in loading manual where maximum still water bending moment occurs.

4.2.3 Loading conditions

4.2.3.1 In general, the design wave loads to be calculated are as follows:

(1) LC1: maximum vertical wave bending moment in way of 1/2L from AP (hogging);
(2) LC2: minimum vertical wave bending moment in way of 1/2L from AP (sagging);
(3) LC3: maximum horizontal wave bending moment in way of 1/2L from AP;
(4) LC4: minimum horizontal wave bending moment in way of 1/2L from AP;
(5) LC5: maximum wave torque in way of 1/4L from AP;
(6) LC6: minimum wave torque in way of 1/4L from AP;
(7) LC7: maximum wave torque in way of 1/2L from AP;
(8) LC8: minimum wave torque in way of 1/2L from AP;
(9) LC9: maximum wave toque in way of 3/4L from AP;
(10) LC10: minimum wave torque in way of 3/4L from AP.

4.2.3.2 The displacements and stresses of the global structure are to be obtained by the loading conditions specified in 4.2.3.1 of this Appendix.

4.2.3.3 The range of dynamic stresses at the edge of hatch corners is to be based on the calculation results

of each loading condition specified in 4.2.3.1 of this Appendix and combined as follows:

$$\Delta\sigma_{12} = \sigma_{LC1} - \sigma_{LC2}$$

$$\Delta\sigma_{34} = \sigma_{LC3} - \sigma_{LC4}$$

$$\Delta\sigma_{56} = \sigma_{LC5} - \sigma_{LC6}$$

$$\Delta\sigma_{78} = \sigma_{LC7} - \sigma_{LC8}$$

$$\Delta\sigma_{910} = \sigma_{LC9} - \sigma_{LC10}$$

where: $\Delta\sigma_{ij}$ — range of stresses under the combined load cases *i* and *j*, taken as the range of tangential stresses at the free edge if the evaluation spot is the free edge of corners or openings, in N/mm^2;

σ_{LCi} — value of stress in load case *i*, taken as the value of tangential stresses at the free edge if the evaluation spot is the free edge of corners or openings, in N/mm^2.

4.3 Structural modeling

4.3.1 General requirements

4.3.1.1 The local fine mesh model is to be in accordance with the requirements of 4.3.2 to 4.3.7 of this Appendix .

4.3.1.2 For the fatigue analysis, the three-dimensional fine mesh model of the local structure may be separated for an individual analysis, applying the displacement results obtained from global three-dimensional coarse mesh finite element analysis to the corresponding boundary nodes as boundary conditions for forced displacements. Alternatively, the fine mesh model may be inserted directly into the global model for analysis. The boundary of fine mesh model is as far as practicable to be taken on the structure of primary supporting and web frames, provided that the following model extent is observed.

4.3.2 Fine mesh model of local structure of hatch corners in the midship region

4.3.2.1 For the local fine mesh model of the midship region, the deck openings where the maximum stress or maximum cross-deck strip warping displacement occurs are in general selected, see Figures 4.3.2.1(1) and (2), and the corresponding extent of model is as follows:

(1) for longitudinal extent, half length of a 40 ft container bay, extending forward and afterward of cross deck strip corner;

(2) for vertical extent, from No.2 deck to the top of hatch coaming;

(3) for transverse extent, from the centerline to ship side, covering hatch corners in way of upper deck and the transitional structure of corners in way of hatch coaming top plate.

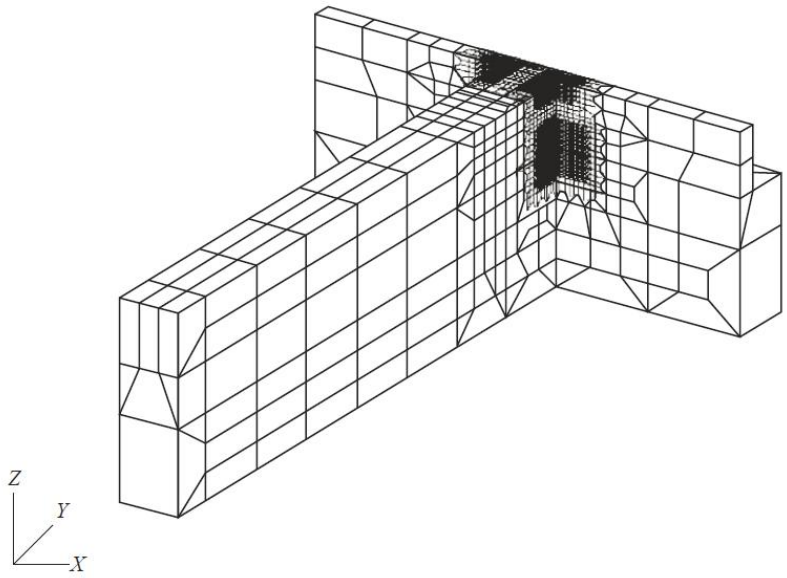

Figure 4.3.2.1(1) FE Model of Hatch Corners in Way of Cargo Hold Area

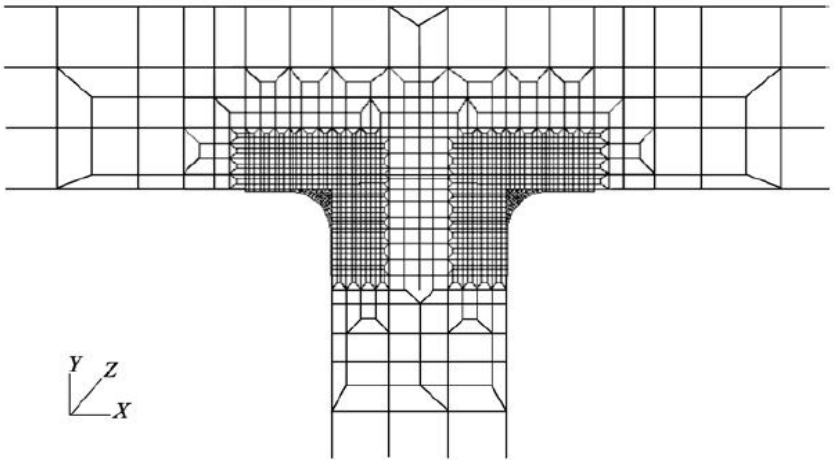

Figure 4.3.2.1(2) FE Model of Hatch Corners in Way of Cargo Hold Area
(Upper Deck Hatch Corners Amplified)

4.3.3 Fine mesh model of local structure of hatch corners at fore end of engine room

4.3.3.1 For the local fine mesh model at the fore end of the engine room, the hatch corners at the front bulkhead of the engine room at portside are to be selected, and the corresponding extent of model is as follows:

(1) for longitudinal extent, half length of a 40 ft container bay extending forward from the front transverse bulkhead of the engine room and a similar distance extending afterward to the transverse web frame (in general, at the mesh line of the transverse web frame of the global model);

(2) for vertical extent, from No.2 deck to hatch coaming (in general, up to the first-tier deck in way of superstructures);

(3) for transverse extent, from the centerline to ship side.

4.3.3.2 All the models are to include upper deck structures with openings, radiused transition structures in way of the hatch coaming top plate and the tapered bracket between the forward end of superstructures and hatch coaming, and their geometry is to be described accurately in the model, see Figures 4.3.3.2(1) to (3).

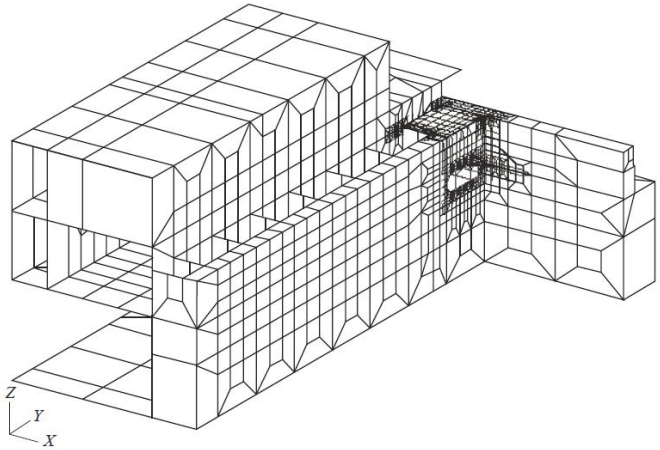

Figure 4.3.3.2(1) FE Model of Hatch Corners in Way of Engine Room Front Bulkhead

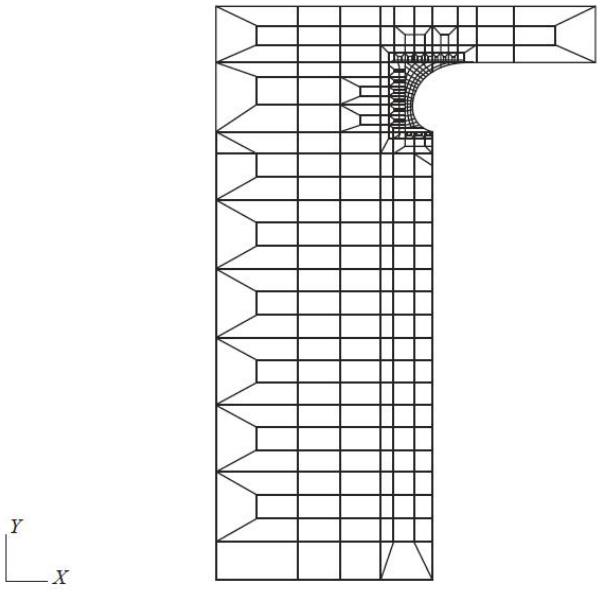

Figure 4.3.3.2(2) FE Model of Hatch Corners in Way of Engine Room Front Bulkhead
(Upper Deck Hatch Corners)

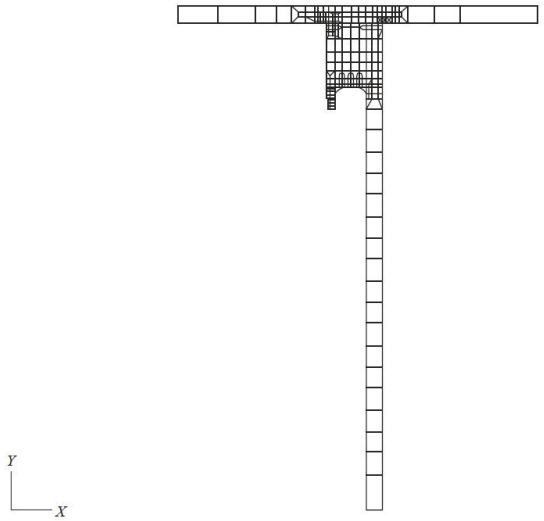

Figure 4.3.3.2(3) FE Model of Hatch Corner in Way of Engine Room Front Bulkhead
(Hatch Coaming Top Plate)

4.3.4 The requirements for the local fine mesh model of hatch corners at the aft end of the engine room and the forward end of No.1 cargo hold are the same as those in 4.3.3.1.

4.3.5 Selection of elements and meshing

4.3.5.1 Plate elements are used to simulate primary structural members such as upper deck, shell plate, longitudinal bulkhead and transverse plates, and beam elements are used to simulate longitudinals and stiffeners. Meshing of the positions where hot-spot stress is checked is shown in 4.3.5.4 of this Appendix.

4.3.5.2 The geometry of radiused corners in upper deck area, radiused top plates of hatch coamings, etc. are to be reflected accurately in the fine mesh model, and all openings (ventilators, access openings) are also to be described accurately in the model.

4.3.5.3 Where the tangential stress at the edge of hatch corners can not be obtained from the finite element analysis program, the method of providing virtual rod elements at the edge of hatch corners to obtain the axial stress of elements is to be used to get the tangential stress, and virtual rod elements may be applied to the following positions:

(1) along the radiused edge of hatch corners at the top level of upper deck and hatch coaming;

(2) along the superstructure to the upper edge of the radiused connecting bracket of longitudinal hatch coaming, if any.

4.3.5.4 The plate elements of areas of hot-spot stress evaluation are to be divided in accordance with the

mesh size of plate thickness × plate thickness ($t \times t$). This mesh density is to be maintained within the fine mesh zone, extending at least10t distance in all directions from the center of hot pot stress to provide a smooth transition to the model boundary.

4.3.6 Boundary conditions

4.3.6.1 The boundary conditions for the global three-dimensional coarse mesh FE model are given in 3.3.4 of this Appendix.

4.3.6.2 Where an independent sub-model is used for analysis, the nodal displacements in way of the boundary of a coarse mesh model, which are obtained from calculations of the above-mentioned loading conditions for the global model, are to be transmitted to corresponding nodes of the fine mesh model as forced displacement boundary conditions of the fine mesh model.

4.4 Fatigue strength evaluation

4.4.1 Assuming that the long-term distribution of the stress ranges of hull structures is a two-parameter Weibull distribution, the shape parameter ξ of Weibull distribution is to be calculated as follows:

$$\xi = 1.45 - 0.036 f\sqrt{L}$$

where: L— length of ship, in m;

$f = 1 - 0.08z/d_1$ for $z \le d_1$;

$f = 0.92+0.08(z - d_1)/(D - d_1)$ for $z > d_1$;

$f = 0.92$ for the calculated point on transverse bulkhead;

D — moulded depth, in m;

d_1— draught in the considered condition, in m;

z— vertical distance from calculation point to baseline, in m.

4.4.2 Design S-N curves are to be selected as follows:

For welding type joint, D curves are selected for fatigue strength evaluation;

For free edge of base metal, C curves are selected for fatigue strength evaluation.

4.4.3 Cumulative damage D_T is to be calculated as follows:

$$D_T = \frac{N_D \alpha}{K} \frac{S_D{}^m}{\left(\ln N_L\right)^{m/\xi}} \mu \Gamma\left(1 + \frac{m}{\xi}\right)$$

where: N_D — total cycles of loads within 20 years' service life of ships, normally taken as 0.65×10^8;

N_L — cycles of load spectrum response circle, taken as 10^8;

α — in-service coefficient of ship, taken as 0.85;

K — S-N curve parameter, see Table 4.4.3(1) of this Appendix;

S_D — design stress ranges, in N/mm^2, calculated as follows:

$$S_D = \max\left(f_c \cdot f_{mean} \cdot f_t \cdot \left|\Delta\sigma_{ij}\right|\right)$$

$\Delta\sigma_{ij}$ — design stress ranges of the combined load cases i and j, see 4.2.3.3 of this Appendix;

fc — corrosion correction factor, taken as 1.07;

f_{mean} — average stress correction factor, selected as follows:

for welding type joint:

$$f_{mean} = \begin{cases} \min\left(1.0, 0.85 + 0.3\sigma_{mean} / \Delta\sigma_{ij}\right), \sigma_{mean} \ge 0 \\ \max\left(0.7, 0.85 + 0.3\sigma_{mean} / \Delta\sigma_{ij}\right), \sigma_{mean} \le 0 \end{cases}$$

for free edge of base metal

$$f_{mean} = \begin{cases} \min\left(1.0, 0.8 + 0.4\sigma_{mean} / \Delta\sigma_{ij}\right), \sigma_{mean} \ge 0 \\ \max\left(0.6, 0.8 + 0.4\sigma_{mean} / \Delta\sigma_{ij}\right), \sigma_{mean} \le 0 \end{cases}$$

σ_{mean} — average stress of considered loading;

f_t — plating thickness correction coefficient, selected as follows:

$$f_t = 1.0 \quad \text{for} \quad t \le 22;$$

$$f_t = \left(\frac{t}{22}\right)^n \text{ for } t > 22;$$

n — coefficient, see Table 4.4.3(2) of this Appendix;

t — plating thickness at hot spot, in mm, taken as the thickness of plating of structure where cracks are easy to occur and extend;

ξ — parameter of Weibull distribution, see 4.4.1 of this Appendix;

m — inverse slope of the *S-N* curve, taken as 3;

Γ — complete GAMMA function values, to be calculated as follows:

$$\Gamma(x) = \int_0^\infty u^{x-1} e^{-u} du$$

$$\mu = 1.0 - \frac{\gamma\left(1+\frac{m}{\xi}, \nu\right) - \nu^{-\frac{\nabla m}{\xi}} \gamma\left(1+\frac{m+\nabla m}{\xi}, \nu\right)}{\Gamma\left(1+\frac{m}{\xi}\right)}$$

$$\nu = \left(\frac{S_q}{S_D}\right)^\xi \ln N_L$$

S_q — stress amplitude values at intersection point of two-slope S-N curves, see Table 4.4.3(1) of this Appendix;

∇m — difference of inverse slope of two-slope S-N curves, taken as 2;

$\gamma(x, \nu)$ — incomplete GAMMA function values, to be calculated as follows:

$$\gamma(x, v) = \int_0^v u^{x-1} e^{-u} du$$

Table 4.4.3(1)

S-N curves	K	S_q
C	3.464×10^{12}	70.2305
D	1.520×10^{12}	53.3680

Table 4.4.3(2)

Structural details	Sketches	Coefficient n
Cruciform joints or transverse T-joints, with weld perpendicular to the direction of load		0.25
Butt joints, with weld perpendicular to the direction of load		0.2
Machine controlled by program or plate with		0.1

Structural details	Sketches	Coefficient n
flame-cut edges, with plate edge parallel to the direction of load		
Plate edge which is ground smooth by machine or other means after cutting		0
Butt welds, attachments on plate edge, with weld parallel to the direction of load		0.1
Attachments on the flat bar or bulb profile, with weld parallel to the direction of load		0
Bracket welded on the plate, with weld parallel to the direction of load, doubling plate		0.2
T section face plate welded with bracket or doubling plates, with weld parallel to the direction of load		0.1

4.4.4 Structure fatigue life is to be calculated as follows:

$$T_F = \frac{20}{D_T}$$

4.4.5 Cumulative damage D_T for structure in its design service life is to meet the following requirement:

$$D_T \leq \frac{20}{T_D}$$

where: T_D — design fatigue life, in year.

Appendix 3 CALCULATION OF SHEAR FLOW

1 General Requirements

This Appendix describes the procedures of direct calculation of shear flow around a ship's cross section due to hull girder vertical shear force. The shear flow q_v at each location in the cross section, is calculated by considering the cross section is subjected to a unit vertical shear force of 1 N in the direction of Z coordinate.

The unit shear flow per mm, q_v, in N/mm, is to be taken as:

$$q_v = q_D + q_l$$

where: q_D — determinate shear flow, as defined in 2;

q_l — indeterminate shear flow which circulates around the closed cells, as defined in 3.

In the calculation of the unit shear flow, q_v, the longitudinal stiffeners are to be taken into account.

2 Determinate Shear Flow

The determinate shear flow, q_D, in N/mm at each location in the cross section is to be obtained from the following line integration:

$$q_D(\mathrm{s}) = -\frac{1}{10^6 I_{y-net}} \int_0^s (z - z_n) t_{net} d_s$$

where: s — coordinate value of running coordinate along the cross section, in m;

$I_{y\text{-}net}$ — net moment of inertia of the cross section, in m^4;

t_{net} — net thickness of plating, in mm;

z_n — Z coordinate of horizontal neutral axis from baseline, in m.

It is assumed that the cross section is composed of line segments as shown in Figure 1: where each line segment has a constant plate net thickness. The determinate shear flow is obtained by the following equation.

$$q_{Dk} = -\frac{t_{net}\ell}{2 \cdot 10^6 I_{Y-net}} (z_k + z_i - 2z_n) + q_{Di}$$

where: q_{Dk}, q_{Di} — determinate shear flow at node k and node i respectively , in N/mm;

l — length of line segments, in m;

y_k, y_i — Y coordinate of the end points k and i of line segment, in m, as defined in Figure 1;

z_k, z_i — Z coordinate of the end points k and i of line segment, in m, as defined in Figure 1.

Where the cross section includes closed cells, the closed cells are to be cut with virtual slits, as shown in Figure 2, in order to obtain the determinate shear flow.

These virtual slits must not be located in walls which form part of another closed cell.

Determinate shear flow at bifurcation points is to be calculated by water flow calculations, or similar, as shown in Figure 2.

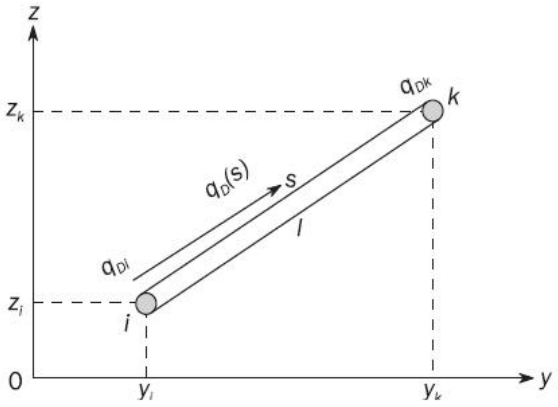

Figure 1 Definition of line segment

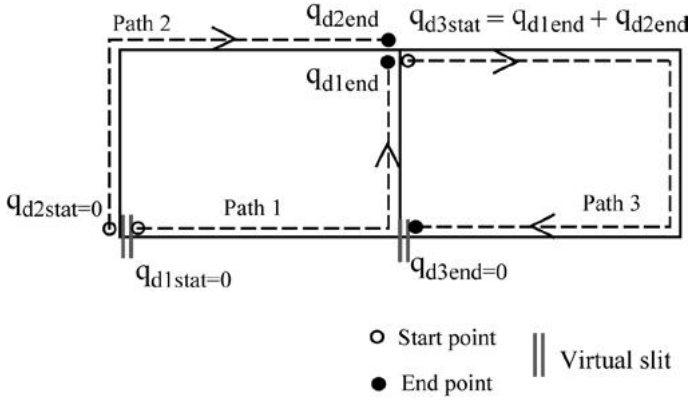

Figure 2 Calculation of determinate shear flow at bifurcation points

3 Indeterminate Shear Flow

The indeterminate shear flow around closed cells of a cross section is considered as a constant value within the same closed cell. The following system of equation for determination of indeterminate shear flows can be developed. In the equations, contour integrations of several parameters around all closed cells are performed.

$$q_{Ic} \oint_c \frac{1}{t_{net}} ds - \sum_{m=1}^{N_w} \left(q_{Im} \oint_{c\&m} \frac{1}{t_{net}} ds \right) = - \oint_c \frac{q_D}{t_{net}} ds$$

where: N_w — number of common walls shared by cell c and all other cells;
$c \,\&\, m$ — common wall shared by cells c and m;
q_{Ic}, q_{Im} — indeterminate shear flow around the closed cell c and m respectively, in N/mm.

Under the assumption of the assembly of line segments shown in Figure 1 and constant plate thickness of each line segment, the above equation can be expressed as follows:

$$q_{Ic} \sum_{j=1}^{N_c} \left(\frac{\ell}{t_{net}} \right)_j - \sum_{m=1}^{N_w} \left\{ q_{Im} \left[\sum_{j=1}^{N_m} \left(\frac{\ell}{t_{net}} \right)_j \right]_m \right\} = - \sum_{j=1}^{Nc} \phi_j$$

$$\phi_j = \left[- \frac{\ell^2}{6 \cdot 10^3 I_{Y-net}} (z_k + 2z_i - 3z_n) + \frac{\ell}{t_{net}} q_{Di} \right]_j$$

where: N_c — number of line segments in cell c;
N_m— number of line segments on the common wall shared by cells c and m;
q_{Di}— determinate shear flow, in N/mm, calculated according to 2.

The difference in the directions of running coordinates specified in 2 and in this section has to be considered.

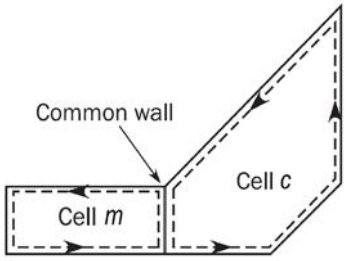

Figure 3 Closed cells and common wall

4 Computation of Sectional Properties

Properties of the cross section are to be obtained by the following formulae where the cross section is assumed as the assembly of line segments:

$$\ell = \sqrt{\left(y_k - y_i\right)^2 + \left(z_k - z_i\right)^2}$$

$$a_{net} = 10^{-3}\ell t_{net} \qquad A_{net} = \sum a_{net}$$

$$s_{y-net} = \frac{a_{net}}{2}(z_k + z_i) \qquad S_{y-net} = \sum s_{y-net}$$

$$i_{y0-net} = \frac{a_{net}}{3}\left(z_k^2 + z_k z_i + z_i^2\right) \qquad I_{y0-net} = \sum i_{y0-net}$$

where: a_{net}, A_{net} — area of the line segment and the cross section respectively, in m^2;

$s_{y\text{-}net}$, $S_{y\text{-}net}$ — first moment of the line segment and the cross section about the baseline, in m^3;

$i_{y0\text{-}net}$, $I_{y0\text{-}net}$ — moment of inertia of the line segment and the cross section about the baseline, in m^4.

The height of horizontal neutral axis, z_n, in m, is to be obtained as follows:

$$z_n = \frac{S_{y-net}}{A_{net}}$$

Inertia moment about the horizontal neutral axis, in m^4, is to be obtained as follows:

$$I_{y-net} = I_{y0-net} - z_n^2 A_{net}$$

Appendix 4 BUCKLING CAPACITY

Symbols

x axis : local axis of a rectangular buckling panel parallel to its long edge;
y axis : local axis of a rectangular buckling panel perpendicular to its long edge;
σ_x : membrane stress applied in *x* direction, in N/mm^2;
σ_y : membrane stress applied in *y* direction, in N/mm^2;
τ : membrane shear stress applied in *xy* plane, in N/mm^2;
σ_a : axial stress in the stiffener, in N/mm^2;
σ_b : bending stress in the stiffener, in N/mm^2;
σ_w : warping stress in the stiffener, in N/mm^2;
$\sigma_{cx}, \sigma_{cy}, \tau_c$: critical stress, in N/mm^2, defined in 2.1.1 of this Appendix for plates;
R_{eH_S} : specified minimum yield stress of the stiffener, in N/mm^2;
R_{eH_P} : specified minimum yield stress of the plate, in N/mm^2;
a : length of the longer side of the plate panel as shown in Table 2, in mm;
b : length of the shorter side of the plate panel as shown in Table 2, in mm;
d : length of the side parallel to the axis of the cylinder corresponding to the curved plate panel as shown in Table 3, in mm;
σ_E : elastic buckling reference stress, in N/mm^2, to be taken as:

(1) for the application of plate limit state according to 2.1.2 of this Appendix:

$$\sigma_E = \frac{\pi^2 E}{12(1-\nu^2)}\left(\frac{t_p}{b}\right)^2;$$

(2) for the application of curved plate panels according to 2.2 of this Appendix:

$$\sigma_E = \frac{\pi^2 E}{12(1-\nu^2)}\left(\frac{t_p}{d}\right)^2;$$

ν : Poisson's ratio to be taken equal to 0.3;
t_p: net thickness of plate panel, in mm;
t_w: net stiffener web thickness, in mm;
t_f: net flange thickness, in mm;
b_f: breadth of the stiffener flange, in mm;
h_w: stiffener web height, in mm;
e_f : Distance from attached plating to centre of flange, in mm, to be taken as:

(1) $e_f = h_w$ for flat bar profile;
(2) $e_f = h_w - 0.5\ t_f$ for bulb profile;
(3) $e_f = h_w + 0.5\ t_f$ for angle and Tee profiles;

α: aspect ratio of the plate panel, to be taken as:

$$\alpha = \frac{a}{b}$$

β: coefficient, to be taken as:

$$\beta = \frac{1-\psi}{\alpha}$$

ψ: edge stress ratio, to be taken as:

$$\psi = \frac{\sigma_2}{\sigma_1}$$

σ_1 : maximum stress, in N/mm^2;
σ_2 : minimum stress, in N/mm^2;
R : radius of curved plate panel, in mm;
ℓ : span, in mm, of stiffener equal to the spacing between primary supporting members;
S : spacing of stiffener, in mm;
ω: factor, to be taken as $\omega = \min(3; \alpha)$.

1 Elementary Plate Panel (EPP)

1.1 Definition

An Elementary Plate Panel (EPP) is the unstiffened part of the plating between stiffeners and/or primary

supporting members.
All the edges of the elementary plate panel are forced to remain straight (but free to move in the in-plane directions) due to the surrounding structure/neighbouring plates (usually longitudinal stiffened panels in deck, bottom and inner-bottom plating, shell and longitudinal bulkheads).

1.2 EPP with different thicknesses

1.2.1 Longitudinally stiffened EPP with different thicknesses

In longitudinal stiffening arrangement, when the plate thickness varies over the width, b, in mm, of a plate panel, the buckling capacity is calculated on an equivalent plate panel width, having a thickness equal to the smaller plate thickness, t_1. The width of this equivalent plate panel, b_{eq}, in mm, is defined by the following formula:

$$b_{eq}=\ell_1+\ell_2\left(\frac{t_1}{t_2}\right)^{1.5}$$

where:

ℓ_1 : width of the part of the plate panel with the smaller plate thickness, t_1, in mm, as defined in Figure 1;

ℓ_2 : width of the part of the plate panel with the greater plate thickness, t_2, in mm, as defined in Figure 1.

Where a panel is consisted of different materials, the minimum yield strength is to be used in buckling assessment.

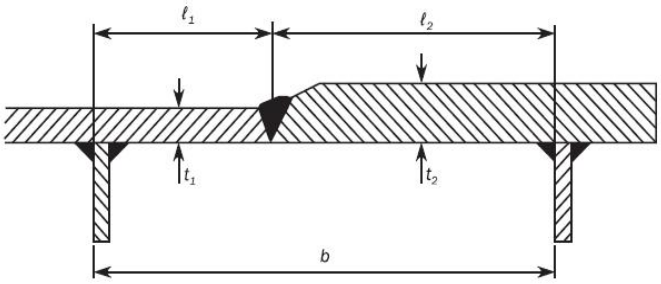

Figure 1 Plate thickness change over the width

1.2.2 Transversally stiffened EPP with different thicknesses

In transverse stiffening arrangement, when an EPP is made of different thicknesses, the buckling check of the plate and stiffeners is to be made for each thickness considered constant on the EPP. The applied stress and lateral pressure is to be measured from the load calculation point of the plate panel.

2 Buckling Capacity of Plates

2.1 Plate panel

2.1.1 Plate limit state

The plate limit state is based on the following interaction formulae. Buckling check under normal stress is for the compression stress, when the normal stress (σ_x, σ_y) is less than zero, the corresponding item is to be deleted and pure shear buckling is to be checked:

(a) longitudinal stiffening arrangement:

$$\left(\frac{\gamma_C\sigma_x}{\sigma_{cx}}\right)^{2/\beta_p^{0.25}}+\left(\frac{\gamma_C|\tau|}{\tau_c}\right)^{2/\beta_p^{0.25}}=1$$

(b) transverse stiffening arrangement:

$$\left(\frac{\gamma_C\sigma_y}{\sigma_{cy}}\right)^{2/\beta_p^{0.25}}+\left(\frac{\gamma_C|\tau|}{\tau_c}\right)^{2/\beta_p^{0.25}}=1$$

where:

σ_x, σ_y — applied normal stress to the plate panel, in N/mm², as defined in 7.2.4.4 of this Chapter;

τ — applied shear stress to the plate panel, in N/mm², as defined in 7.2.4.4 of this Chapter;

σ_{cx} — ultimate buckling stress, in N/mm², in direction parallel to the longer edge of buckling panel as defined in 2.1.3 of this Appendix;

σ_{cy} — ultimate buckling stress, in N/mm², in direction parallel to the shorter edge of buckling panel as defined in 2.1.3 of this Appendix;

τ_c — ultimate buckling shear stress, in N/mm², as defined in 2.1.3 of this Appendix;

β_p — plate slenderness parameter, to be taken as:

$$\beta_p = \frac{b}{t_p}\sqrt{\frac{R_{eH_P}}{E}}$$

2.1.2 Reference degree of slenderness

The reference degree of slenderness is to be taken as:

$$\lambda = \sqrt{\frac{R_{eH_P}}{K\sigma_E}}$$

where:

K — buckling factor, as defined in Table 2 and Table 3.

2.1.3 Ultimate buckling stresses

The ultimate buckling stress of plate panels, in N/mm², is to be taken as:

$$\sigma_{cx} = C_x R_{eH_P}$$

$$\sigma_{cy} = C_y R_{eH_P}$$

The ultimate buckling stress of plate panels subject to shear, in N/mm², is to be taken as:

$$\tau_c = C_\tau \frac{R_{eH_P}}{\sqrt{3}}$$

where:

C_x, C_y, C_τ — reduction factors, as defined in Table 2.

The boundary conditions for plates are to be considered as simply supported (see cases 1, 2 and 15 of Table 2). If the boundary conditions differ significantly from simple support, a more appropriate boundary condition can be applied according to the different cases of Table 2 subject to the agreement of CCS.

2.1.4 Correction factor F_{long}

The correction factor F_{long} depending on the edge stiffener types on the longer side of the buckling panel is defined in Table 1. An average value of F_{long} is to be used for plate panels having different edge stiffeners. For stiffener types other than those mentioned in Table 1, the value of c is to be agreed by CCS. In such a case, value of c higher than those mentioned in Table 1 can be used, provided it is verified by buckling strength check of panel using non-linear FE analysis and deemed appropriate by CCS.

Edge boundary conditions: - - - - - - - - - Plate edge free ——————— Plate edge simply supported ▬▬▬▬▬▬ Plate edge clamped.				
Note: (1) Cases listed are general cases. Each stress component (σ_x, σ_y) is to be understood in local coordinates.				

2.2 Curved plate panels

This requirement for curved plate limit state is applicable when $R/t_p \le 2500$. Otherwise, the requirement for plate limit state given in 2.1.1 of this Appendix is applicable.

The curved plate limit state is based on the following interaction formula:

$$\left(\frac{\gamma_c \sigma_{ax}}{C_{ax} R_{eH_P}}\right)^{1.25} + \left(\frac{\gamma_c \tau\sqrt{3}}{C_\tau R_{eH_P}}\right)^2 = 1.0$$

where:

σ_{ax} — applied axial stress to the cylinder corresponding to the curved plate panel, in N/mm². In case of tensile axial stresses, σ_{ax}= 0;

C_{ax}, C_τ — buckling reduction factor of the curved plate panel, as defined in Table 3.

The stress multiplier factor γ_c of the curved plate panel needs not be taken less than the stress multiplier factor γ_c for the expanded plane panel according to 2.1.1 of this Appendix.

Buckling Factor and reduction factor for curved plate panel with $R/t_p \le 2500$ Table 3

Case	Aspect ratio	Buckling factor K	Reduction factor C
1 	$\frac{d}{R} \le 0.5\sqrt{\frac{R}{t_p}}$	$K = 1 + \frac{2}{3}\frac{d^2}{Rt_p}$	For general application: $C_{ax} = 1$ for $\lambda \le 0.25$ $C_{ax} = 1.233\text{-}0.933\lambda$ for $0.25 < \lambda \le 1$ $C_{ax} = 0.3/\lambda^3$ for $1 < \lambda \le 1.5$ $C_{ax} = 0.2/\lambda^2$ for $\lambda > 1.5$ For curved single fields, e.g. bilge strake, which are bounded by plane panels: $C_{ax} = 0.65/\lambda^2 \le 1.0$
	$\frac{d}{R} > 0.5\sqrt{\frac{R}{t_p}}$	$K = 0.267\frac{d^2}{Rt_p}\left[3 - \frac{d}{R}\sqrt{\frac{t_p}{R}}\right] \ge 0.4\frac{d^2}{Rt_p}$	
2 	$\frac{d}{R} \le 8.7\sqrt{\frac{R}{t_p}}$	$K = \sqrt{3}\sqrt{28.3 + \frac{0.67d^3}{R^{1.5}t_p^{1.5}}}$	$C_\tau = 1$ for $\lambda \le 0.4$ $C_\tau = 1.274 - 0.686\lambda$ for $0.4 < \lambda \le 1.2$ $C_\tau = 0.65/\lambda^2$ for $\lambda > 1.2$
	$\frac{d}{R} > 8.7\sqrt{\frac{R}{t_p}}$	$K = \sqrt{3}\frac{0.28d^2}{R\sqrt{Rt_p}}$	
Explanations for boundary conditions: ——— Plate edge simply supported.			

3 Buckling Capacity of Overall Stiffened Panel

The elastic stiffened panel limit state is based on the following interaction formula:

$$\frac{P_Z}{c_f} = 1$$

where: P_z and c_f are defined in 4.4.3 of this Appendix.

4 Buckling Capacity of Longitudinal Stiffeners

4.1 Stiffeners limit states

The buckling capacity of longitudinal stiffeners is to be checked for the following limit states:
(1) stiffener induced failure (SI);
(2) associated plate induced failure (PI).

4.2 Lateral pressure

The lateral pressure is to be considered as constant in the buckling strength assessment of longitudinal stiffeners.

4.3 Stiffener idealization

4.3.1 Effective length of the stiffener ℓ_{eff}

The effective length of the stiffener ℓ_{eff}, in mm, is to be taken equal to:

(1) $\ell_{eff} = \frac{\ell}{\sqrt{3}}$ for stiffener fixed at both ends;

(2) $\ell_{eff} = 0.75\ell$ for stiffener simply supported at one end and fixed at the other;

(3) $\ell_{eff} = \ell$ for stiffener simply supported at both ends.

4.3.2 Effective width of the attached plating b_{eff1}

The effective width of the attached plating of a stiffener b_{eff1}, in mm, without the shear lag effect is to be taken equal to:

$$b_{eff1} = \frac{C_{x1}b_1 + C_{x2}b_2}{2}$$

where:

C_{x1}, C_{x2} — reduction factor defined in Table 2 calculated for each side of the considered stiffener according to case 1;

b_1, b_2 — width of plate panel on each side of the considered stiffener, in mm.

4.3.3 Effective width of attached plating b_{eff}

The effective width of attached plating of stiffeners, b_{eff}, in mm, is to be taken as:

$$b_{eff} = min\left(b_{eff1}, \chi_s s\right)$$

where:

χ_s — effective width coefficient to be taken as:

- $\chi_s = min\left[\frac{1.12}{1+\frac{1.75}{\left(\frac{\ell_{eff}}{s}\right)^{1.6}}}; 1\right]$ for $\frac{\ell_{eff}}{s} \geq 1$
- $\chi_s = 0.407\frac{\ell_{eff}}{s}$ for $\frac{\ell_{eff}}{s} < 1$

4.3.4 Net thickness of attached plating t_p

The net thickness of plate t_p, in mm, is to be taken as the mean thickness of the two attached plating panels.

4.3.5 Effective web thickness of flat bar

For accounting the decrease of stiffness due to local lateral deformation, the effective web thickness of flat bar stiffener, in mm, is to be used for the calculation of the net sectional area, A_s, the net section modulus, Z, and the moment of inertia, I, of the stiffener and is taken as:

$$t_{w_red} = t_w\left(1-\frac{2\pi^2}{3}\left(\frac{h_w}{s}\right)^2\left(1-\frac{b_{eff1}}{s}\right)\right)$$

4.3.6 Net section modulus Z of a stiffener

The net section modulus Z of a stiffener, in cm^3, including effective width of plating b_{eff} is to be taken equal to:

(1) the section modulus calculated at the top of stiffener flange for stiffener induced failure (SI).

(2) the section modulus calculated at the attached plating for plate induced failure (PI).

4.3.7 Net moment of inertia I of a stiffener

The net moment of inertia I, in cm^4, of a stiffener including effective width of attached plating b_{eff} is to comply with the following requirement:

$$I \geq \frac{s\, t_p^{\,3}}{12{\cdot}10^4}.$$

4.3.8 Idealisation of bulb profile

Bulb profiles may be considered as equivalent angle profiles. The net dimensions of the equivalent built-up section are to be obtained, in mm, from the following formulae:

$$h_w = h'_w - \frac{h'_w}{9.2} + 2$$

$$b_f = \alpha\left(t'_w + \frac{h'_w}{6.7} - 2\right)$$

$$t_f = \frac{h'_w}{9.2} - 2$$

$$t_w = t'_w$$

where: h'_w, t'_w — net height and thickness of a bulb section, in mm, as shown in Figure 2;

α — coefficient equal to:

$$\alpha = 1.1 + \frac{(120 - h'_w)^2}{3000} \quad \text{for} \quad h'_w \leq 120$$

$$\alpha = 1.0 \quad \text{for} \quad h'_w > 120$$

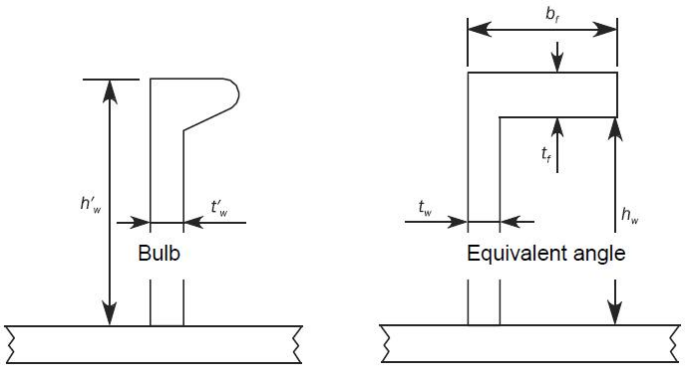

Figure 2 Idealisation of bulb stiffener

4.4 Ultimate buckling capacity

4.4.1 Longitudinal stiffener limit state

When $\sigma_a + \sigma_b + \sigma_w > 0$, the ultimate buckling capacity for stiffeners is to be checked according to the following interaction formula:

$$\frac{\gamma_c \sigma_a + \sigma_b + \sigma_w}{R_{eH}} = 1$$

where:

σ_a — effective axial stress, in N/mm², at mid-span of the stiffener, defined in 4.4.2 of this Appendix;

σ_b — bending stress in the stiffener, in N/mm², defined in 4.4.3 of this Appendix;

σ_w — stress due to torsional deformation, in N/mm², defined in 4.4.4 of this Appendix;

R_{eH} — specified minimum yield stress of the material, in N/mm²:

(1) $R_{eH} = R_{eH_S}$ for stiffener induced failure (SI);

(2) $R_{eH} = R_{eH_P}$ for plate induced failure (PI).

4.4.2 Effective axial stress σ_a

The effective axial stress σ_a, in N/mm², at mid-span of the stiffener, acting on the stiffener with its attached plating is to be taken equal to:

$$\sigma_a = \sigma_x \frac{s t_p + A_s}{b_{eff1} t_p + A_s}$$

where:

σ_x — nominal axial stress, in N/mm², acting on the stiffener with its attached plating, calculated according to 7.2.4.4.1 a) of this Chapter;

A_s — net sectional area, in mm², of the considered stiffener.

4.4.3 Bending stress σ_b

The bending stress in the stiffener σ_b, in N/mm², is to be taken equal to:

$$\sigma_b = \frac{M_o + M_1}{1000\, Z}$$

where:

M_1 — bending moment, in Nmm, due to the lateral load P:

(1) $M_1 = C_i \frac{|P| s \ell^2}{24 \cdot 10^3}$ for continuous stiffener;

(2) $M_1 = C_i \frac{|P| s \ell^2}{8 \cdot 10^3}$ for sniped stiffener;

P — lateral load, in kN/m², to be equal to the static pressure at the load calculation point of the stiffener;

C_i — pressure coefficient;

(1) $C_i = C_{SI}$ for stiffener induced failure (SI);

(2) $C_i = C_{PI}$ for plate induced failure (PI);

C_{PI} — plate induced failure pressure coefficient:

(1) $C_{PI} = 1$ if the lateral pressure is applied on the side opposite to the stiffener;

(2) $C_{PI}=-1$ if the lateral pressure is applied on the same side as the stiffener;

C_{SI} — stiffener induced failure pressure coefficient:

(1) $C_{SI}=-1$ if the lateral pressure is applied on the side opposite to the stiffener;

(2) $C_{SI}=1$ if the lateral pressure is applied on the same side as the stiffener;

M_0 — bending moment, in Nmm, due to the lateral deformation w of stiffener:

$$M_0 = F_E\left(\frac{P_z w}{c_f - P_z}\right), \text{ with } c_f - P_z > 0;$$

F_E — ideal elastic buckling force of the stiffener, in N:

$$F_E=\left(\frac{\pi}{\ell}\right)^2 EI\cdot 10^4;$$

P_z — normal lateral load, in N/mm^2, acting on stiffeners due to stresses σ_x, σ_y and τ, in the attached plating in way of stiffener mid span:

$$P_z=\frac{t_p}{s}\left(\sigma_{xl}\left(\frac{\pi s}{\ell}\right)^2+\sqrt{2}\,\tau_1\right);$$

$$\sigma_{x\ell} = \gamma_c\sigma_x\left(1+\frac{A_s}{st_p}\right), \text{ but not less than 0;}$$

$$\tau_1=\gamma|\tau|-t_p\sqrt{R_{eH_P}\,E\left(\frac{m_1}{a^2}+\frac{m_2}{b^2}\right)}, \text{ but not less than 0;}$$

m_1, m_2 — coefficients, taken equal to:

(1) $m_1 = 1.47$, $m_2 = 0.49$ for $\alpha\geq 2$;

(2) $m_1 = 1.96$, $m_2 = 0.37$ for $\alpha<2$;

w — deformation of stiffener, in mm, taken equal to:

$$w = w_0 + w_1;$$

w_0 — assumed imperfection, in mm, taken equal to:

(1) $w_0=\ell/1000$ in general;

(2) $w_0=-w_{na}$ for stiffeners sniped at both ends, considering stiffener induced failure (SI);

(3) $w_0=w_{na}$ for stiffeners sniped at both ends, considering plate induced failure (PI);

w_{na} — distance, in mm, from the mid-point of attached plating to the neutral axis of the stiffener calculated with the effective width of the attached plating;

w_1 — deformation of stiffener at midpoint of stiffener span due to lateral load P, in mm. In case of uniformly distributed load, w_1 is to be taken as:

(1) $w_1=C_i\frac{|P|\,s\,\ell^4}{384\cdot 10^7 E\,I}$ in general;

(2) $w_1=C_i\frac{5|P|\,s\,\ell^4}{384\cdot 10^7 E\,I}$ for stiffener sniped at both ends;

c_f — elastic support provided by the stiffener, in N/mm^2, to be taken equal to:

$$c_f=F_E\left(\frac{\pi}{\ell}\right)^2(1+c_p);$$

c_p — coefficient, to be taken as:

$$c_p=\frac{1}{1+\frac{0.91}{c_{xa}}\left(\frac{12I}{st_p^3}10^4-1\right)}$$

c_{xa} — coefficient, to be taken as:

(1) $c_{xa}=\left[\frac{\ell}{2s}+\frac{2s}{\ell}\right]^2$ for $\ell\geq 2s$;

(2) $c_{xa}=\left[1+\left(\frac{\ell}{2s}\right)^2\right]^2$ for $\ell<2s$.

4.4.4 Stress due to torsional deformation σ_w

The stress due to torsional deformation σ_w, in N/mm^2, is to be taken equal to:

(1) $\sigma_w = Ey_w\left(\frac{t_f}{2} + h_w\right)\Phi_0\left(\frac{\pi}{\ell}\right)^2\left(\frac{1}{1 - \frac{0.4R_{eH_S}}{\sigma_{ET}}} - 1\right)$ for stiffener induced failure (SI);

(2) $\sigma_w = 0$ for plate induced failure (PI).

where:

y_w — distance, in mm, from centroid of stiffener cross-section to the free edge of stiffener flange, to be taken as:

(1) $y_w = \frac{t_w}{2}$ for flat bar;

(2) $y_w = b_f - \frac{h_w t_w^2 + t_f b_f^2}{2A_s}$ for angle and bulb profiles;

(3) $y_w = \frac{b_f}{2}$ for Tee profile;

Φ_0 — coefficient, to be taken as:

$\Phi_0 = \frac{\ell}{h_w}10^{-3}$;

σ_{ET} — reference stress for torsional buckling, in N/mm^2:

$\sigma_{ET} = \frac{E}{I_p}\left(\frac{\varepsilon\pi^2 I_\omega 10^2}{\ell^2} + 0.385 I_T\right)$

I_p — net polar moment of inertia of the stiffener about point *C* as shown in Figure 3, as defined in Table 4, in cm^4;

I_T — net St. Venant's moment of inertia of the stiffener, as defined in Table 4, in cm^4;

I_ω — net sectional moment of inertia of the stiffener about point *C* as shown in Figure 3, as defined in Table 4, in cm^6;

ε — degree of fixation, to be taken as:

$$\varepsilon = 1 + \frac{\left(\frac{\ell}{\pi}\right)^2 10^{-3}}{\sqrt{I_\omega\left(\frac{0.75s}{t_p^3} + \frac{e_f - 0.5t_f}{t_w^3}\right)}}.$$

Moments of inertia **Table 4**

Characteristics of cross section	Flat bars	Bulb, angle and Tee profiles
I_P	$\frac{h_w^3 t_w}{3\cdot 10^4}$	$\left(\frac{A_w(e_f - 0.5t_f)^2}{3} + A_f e_f^2\right)10^{-4}$
I_T	$\frac{h_w t_w^3}{3\cdot 10^4}\left(1 - 0.63\frac{t_w}{h_w}\right)$	$\frac{(e_f - 0.5t_f)t_w^3}{3\cdot 10^4}\left(1 - 0.63\frac{t_w}{e_f - 0.5t_f}\right)$ + $\frac{b_f t_f^3}{3\cdot 10^4}\left(1 - 0.63\frac{t_f}{b_f}\right)$
I_ω	$\frac{h_w^3 t_w^3}{36\cdot 10^6}$	$\frac{A_f e_f^2 b_f^2}{12\cdot 10^6}\left(\frac{A_f + 2.6A_w}{A_f + A_w}\right)$ for bulb and angle profiles $\frac{b_f^3 t_f e_f^2}{12\cdot 10^6}$ for Tee profiles
A_w: net web area, in mm^2; A_f: net flange area, in mm^2.		

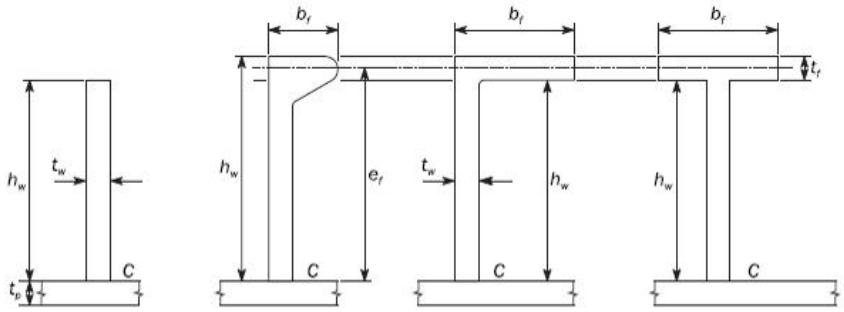

Figure 3 Stiffener cross sections

Appendix 5 HULL GIRDER ULTIMATE BENDING CAPACITY

Symbols

$I_{y\text{-}net}$: net moment of inertia, in m^4, of the hull transverse section around its horizontal neutral axis;

$Z_{B\text{-}net}$, $Z_{D\text{-}net}$: section moduli, in m^3, at bottom and deck, respectively;

R_{eH_S}: minimum yield stress, in N/mm^2, of the material of the considered stiffener;

R_{eH_P}: minimum yield stress, in N/mm^2, of the material of the considered plate;

$A_{s\text{-}net}$: net sectional area, in cm^2, of stiffener, without attached plating;

$A_{p\text{-}net}$: net sectional area, in cm^2, of attached plating.

1 General Assumptions

1.1 The method for calculating the ultimate hull girder capacity is to identify the critical failure modes of all main longitudinal structural elements.

1.2 Structures compressed beyond their buckling limit have reduced load carrying capacity. All relevant failure modes for individual structural elements, such as plate buckling, torsional stiffener buckling, stiffener web buckling, lateral or global stiffener buckling and their interactions, are to be considered in order to identify the weakest inter-frame failure mode.

2 Incremental-Iterative Method

2.1 Assumptions

In applying the incremental-iterative method, the following assumptions are generally to be made:

- The ultimate strength is calculated at hull transverse sections between two adjacent transverse webs.
- The hull girder transverse section remains plane during each curvature increment.
- The hull material has an elasto-plastic behaviour.
- The hull girder transverse section is divided into a set of elements, see 2.2.2 of this Appendix, which are considered to act independently.

According to the iterative procedure, the bending moment M_i acting on the transverse section at each curvature value χ_i is obtained by summing the contribution given by the stress σ acting on each element. The stress σ corresponding to the element strain, ε is to be obtained for each curvature increment from the non-linear load-end shortening curves σ-ε of the element.

These curves are to be calculated, for the failure mechanisms of the element, from the formulae specified in 2.3. The stress σ is selected as the lowest among the values obtained from each of the considered load-end shortening curves σ-ε.

The procedure is to be repeated until the value of the imposed curvature reaches the value χ_F, in m^{-1}, in hogging and sagging conditions, obtained from the following formula:

$$\chi_F = \pm\, 0.003 \frac{M_y}{EI_{y-net}}$$

where: M_Y — lesser of the values M_{Y1} and M_{Y2}, in kN·m.;

$M_{Y1} = 10^3\, R_{eH}\, ZB\text{-}net.$

$M_{Y2} = 10^3\, R_{eH}\, ZD\text{-}net.$

If the value χ_F is not sufficient to evaluate the peaks of the curve M-χ, the procedure is to be repeated until the value of the imposed curvature permits the calculation of the maximum bending moments of the curve.

2.2 Procedure

2.2.1 General

The curve M-χ is to be obtained by means of an incremental-iterative approach, summarized in the flow chart in Figure 1.

In this procedure, the ultimate hull girder bending moment capacity, M_U is defined as the peak value of the curve with vertical bending moment M versus the curvature χ of the ship cross section as shown in Figure 1.

The curve is to be obtained through an incrementaliterative approach.
Each step of the incremental procedure is represented by the calculation of the bending moment M_i which acts on the hull transverse section as the effect of an imposed curvature χ_i.
For each step, the value χ_i is to be obtained by summing an increment of curvature, $\Delta\chi$ to the value relevant to the previous step χ_{i-1}. This increment of curvature corresponds to an increment of the rotation angle of the hull girder transverse section around its horizontal neutral axis.
This rotation increment induces axial strains ε in each hull structural element, whose value depends on the position of the element. In hogging condition, the structural elements above the neutral axis are lengthened, while the elements below the neutral axis are shortened, and vice-versa in sagging condition.
The stress σ induced in each structural element by the strain ε is to be obtained from the load-end shortening curve σ-ε of the element, which takes into account the behaviour of the element in the non-linear elasto-plastic domain.
The distribution of the stresses induced in all the elements composing the hull transverse section determines, for each step, a variation of the neutral axis position due to the nonlinear σ-ε, relationship. The new position of the neutral axis relevant to the step considered is to be obtained by means of an iterative process, imposing the equilibrium among the stresses acting in all the hull elements on the transverse section.
Once the position of the neutral axis is known and the relevant element stress distribution in the section is obtained, the bending moment of the section M_i around the new position of the neutral axis, which corresponds to the curvature χ_i imposed in the step considered, is to be obtained by summing the contribution given by each element stress.
The main steps of the incremental-iterative approach described above are summarised as follows (see also Figure 1):

Step 1: Divide the transverse section of hull into stiffened plate elements.

Step 2: Define stress-strain relationships for all elements as shown in Table 1.

Step 3: Initialise curvature χ_1 and neutral axis for the first incremental step with the value of incremental curvature (i.e. curvature that induces a stress equal to 1% of yield strength in strength deck) as:

$$\chi_1=\Delta\chi = 0.01\frac{R_{eH}}{E}\frac{1}{z_D - z_n}$$

where: z_D — Z coordinate, in m, of strength deck at side;
z_n — Z coordinate, in m, of horizontal neutral axis of the hull transverse section with respect to the reference coordinate system defined in 7.2.1.2, Section 2 of this Chapter.

Step 4: Calculate for each element the corresponding strain, $\varepsilon_i=\chi(z_i-z_n)$ and the corresponding stress σ_i.

Step 5: Determine the neutral axis z_{NA_cur} at each incremental step by establishing force equilibrium over the whole transverse section as:
$\Sigma A_{i\text{-}net}\,\sigma_i = \Sigma A_{j\text{-}net}\,\sigma_j$ (i-th element is under compression, j-th element under tension).

Step 6: Calculate the corresponding moment by summing the contributions of all elements as:

$$M_U = \sum \sigma_{Ui} A_{i-net}\left|\left(z_i - z_{NA_cur}\right)\right|.$$

Step 7: Compare the moment in the current incremental step with the moment in the previous incremental step. If the slope in M-χ relationship is less than a negative fixed value, terminate the process and define the peak value M_U. Otherwise, increase the curvature by the amount of $\Delta\chi$ and go to Step 4.

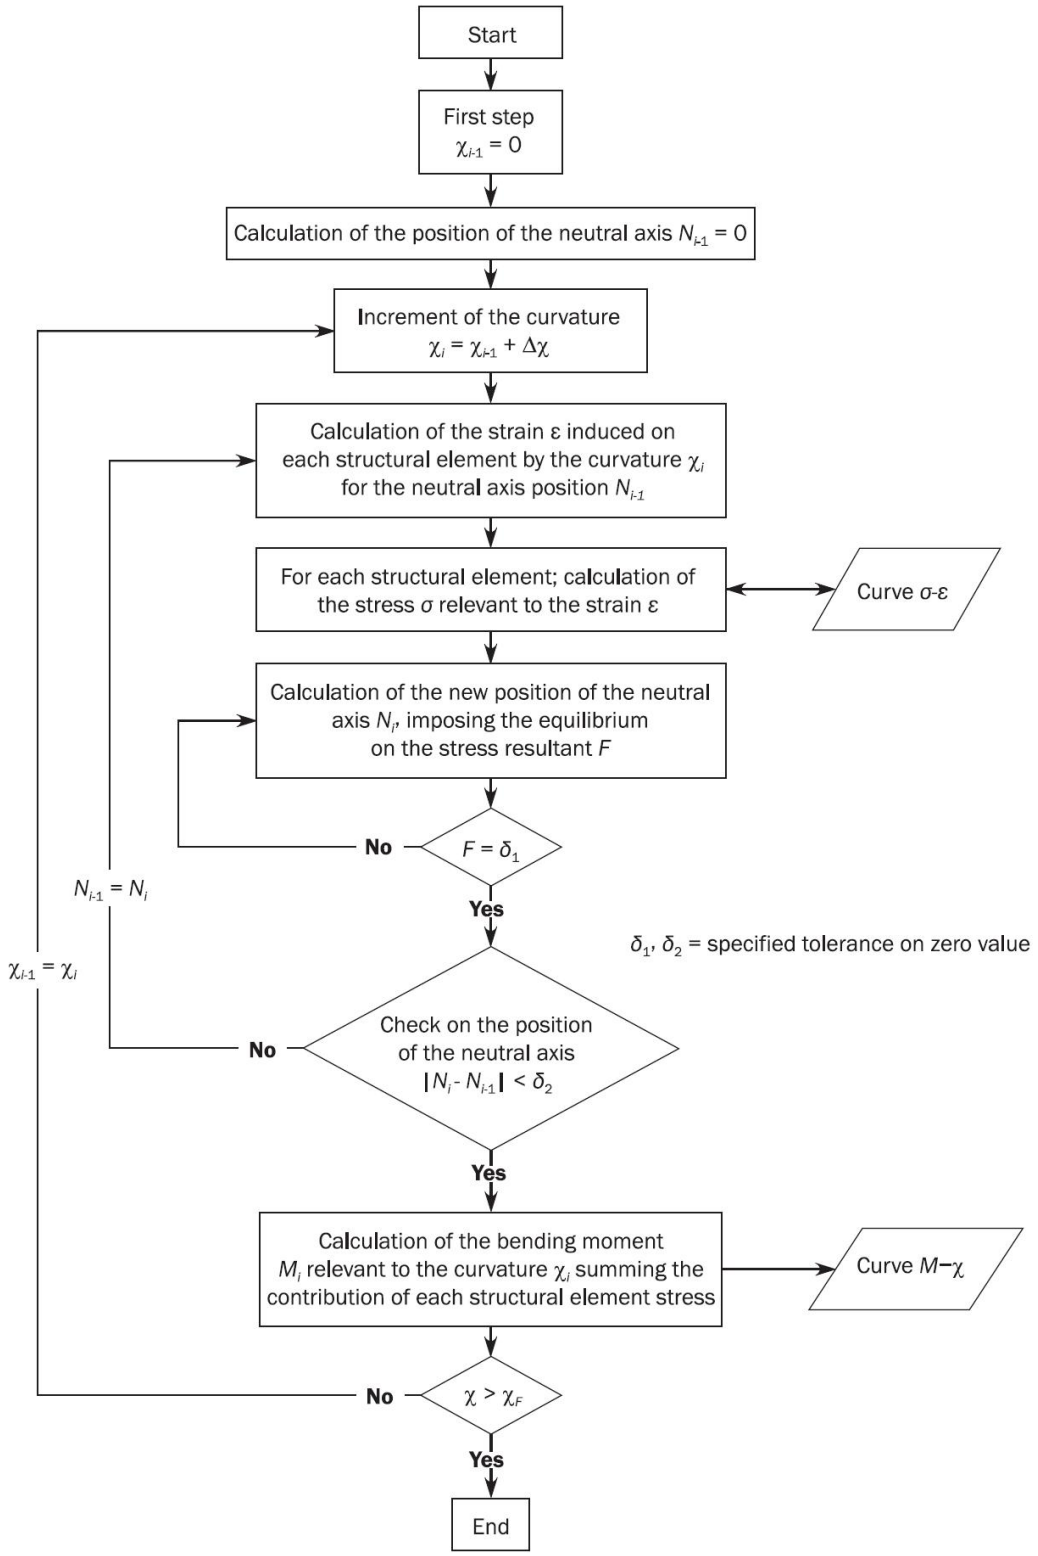

Figure 1 Flow chart of the procedure for the evaluation of the curve *M-χ*

2.2.2 Modelling of the hull girder cross section

Hull girder transverse sections are to be considered as being constituted by the members contributing to the hull girder ultimate strength.

Sniped stiffeners are also to be modelled, taking account that they do not contribute to the hull girder strength.

The structural members are categorised into a stiffener element, a stiffened plate element or a hard corner element.

The plate panel including web plate of girder or side stringer is idealised into a stiffened plate element, an

attached plate of a stiffener element or a hard corner element.
The plate panel is categorised into the following two kinds:

— longitudinally stiffened panel of which the longer side is in ship's longitudinal direction, and
— transversely stiffened panel of which the longer side is in the perpendicular direction to ship's longitudinal direction.

• Hard corner element:
Hard corner elements are sturdier elements composing the hull girder transverse section, which collapse mainly according to an elasto-plastic mode of failure (material yielding); they are generally constituted by two plates not lying in the same plane.
The extent of a hard corner element from the point of intersection of the plates is to be taken equal to 20 t_{net} on a transversely stiffened panel and to 0.5 s on a longitudinally stiffened panel, see Figure 2.
where:

t_{net} — net thickness of plate, in mm;
s — spacing of the adjacent longitudinal stiffener, in m.

Bilge, sheer strake-deck stringer elements, girder-deck connections and face plate-web connections on large girders are typical hard corners.
• Stiffener element:
The stiffener constitutes a stiffener element together with the attached plate.
The attached plate width is in principle:

— equal to the mean spacing of the stiffener when the panels on both sides of the stiffener are longitudinally stiffened, or
— equal to the width of the longitudinally stiffened panel when the panel on one side of the stiffener is longitudinally stiffened and the other panel is of the transversely stiffened, see Figure 2.

• Stiffened plate element:
The plate between stiffener elements, between a stiffener element and a hard corner element or between hard corner elements is to be treated as a stiffened plate element, see Figure 2.

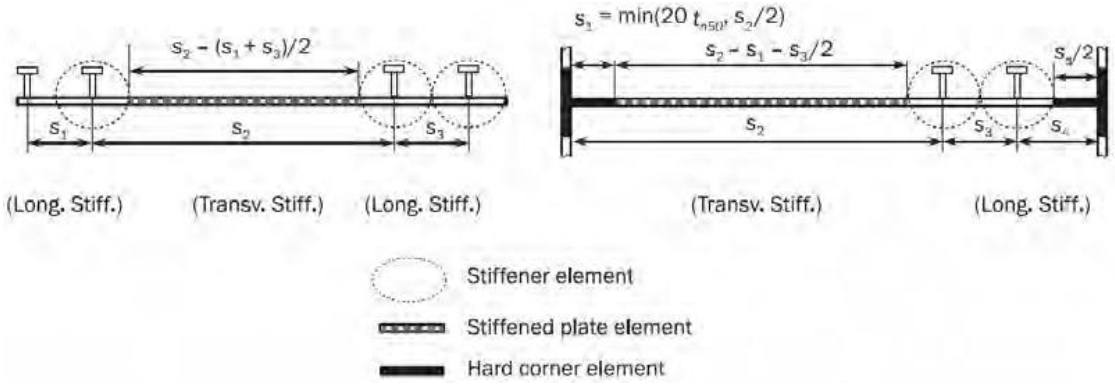

Figure 2 Extension of the breadth of the attached plating and hard corner element

The typical examples of modelling of hull girder section are illustrated in Figure 3.
Notwithstanding the foregoing principle, these figures are to be applied to the modelling in the vicinity of upper deck, sheer strake and hatch coaming.

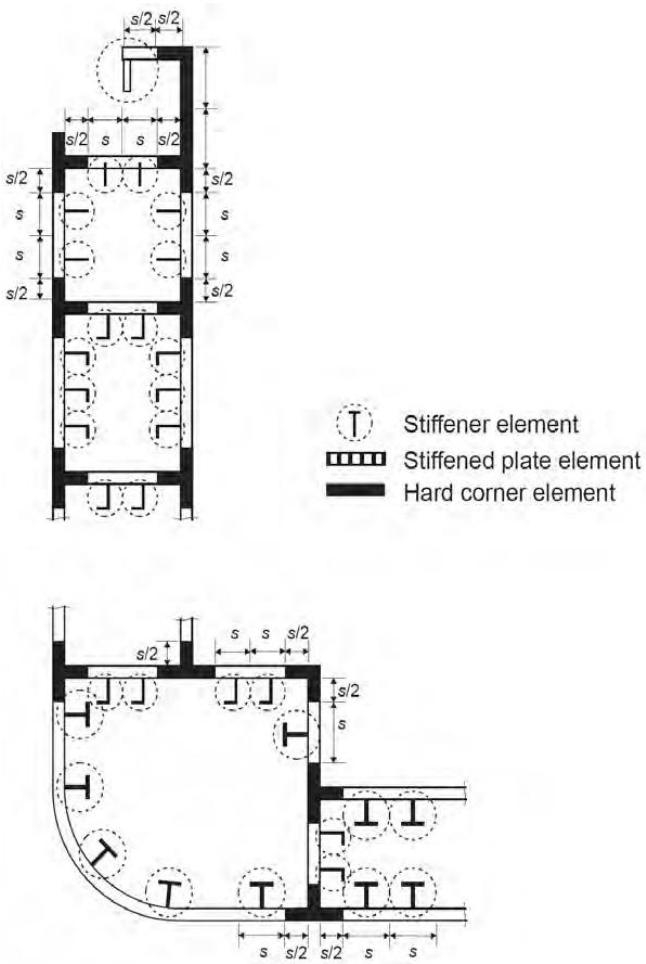

Figure 3 Examples of the configuration of stiffened plate elements, stiffener elements and hard corner elements on a hull section

Notes:

(1) In case of the knuckle point as shown in Figure 4, the plating area adjacent to knuckles in the plating with an angle greater than 30 degrees is defined as a hard corner. The extent of one side of the corner is taken equal to 20 t_{net} on transversely framed panels and to 0.5 s on longitudinally framed panels from the knuckle point.

(2) Where the plate members are stiffened by non-continuous longitudinal stiffeners, the non- continuous stiffeners are considered only as dividing a plate into various elementary plate panels.

(3) Where the opening is provided in the stiffened plate element, the openings are to be considered in accordance with the requirements of Figure 2.2.4.7 of Section 2, Chapter 2 of this PART.

(4) Where attached plating is made of steels having different thicknesses and/or yield stresses, an average thickness and/or average yield stress obtained from the following formula are to be used for the calculation:

$$t_{net} = \frac{t_{1-net}s_1 + t_{2-net}s_2}{s} \qquad R_{eH_P} = \frac{R_{eH_P1}t_{1-net}s_1 + R_{eH_P2}t_{2-net}s_2}{t_{net}s}$$

where: R_{eH_p1}, R_{eH_p2}, $t_{1\text{-}net}$, $t_{2\text{-}net}$, s_1, s_2 and s are shown in Figure 5.

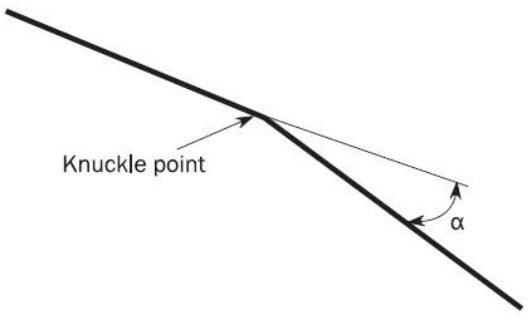

Figure 4 Plating with knuckle point

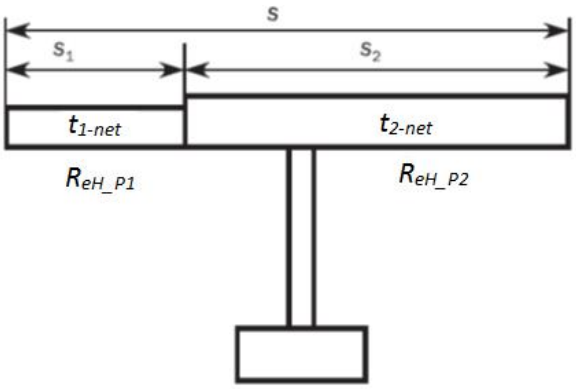

Figure 5 Element with different thickness and yield strength

2.3 Load-end shortening curves

2.3.1 Stiffened plate element and stiffener element

Stiffened plate element and stiffener element composing the hull girder transverse sections may collapse following one of the modes of failure specified in Table 1.

- Where the plate members are stiffened by non-continuous longitudinal stiffeners, the stress of the element is to be obtained in accordance with 2.3.2 to 2.3.7 of this Appendix, taking into account the non-continuous longitudinal stiffener.

In calculating the total forces for checking the hull girder ultimate strength, the area of non-continuous longitudinal stiffener is to be assumed as zero.

- Where the opening is provided in the stiffened plate element, the considered area of the stiffened plate element is to be obtained by deducting the opening area from the plating in calculating the total forces for checking the hull girder ultimate strength.
- For stiffened plate element, the effective width of plate for the load shortening portion of the stress-strain curve is to be taken as full plate width, i.e. to the intersection of other plate or longitudinal stiffener – neither from the end of the hard corner element nor from the attached plating of stiffener element, if any. In calculating the total forces for checking the hull girder ultimate strength, the area of the stiffened plate element is to be taken between the hard corner element and the stiffener element or between the hard corner elements, as applicable.

Modes of failure of stiffened plate element and stiffener element Table 1

Element	Mode of failure	Curve σ-ε defined in
Lengthened stiffened plate element or stiffener element	Elasto-plastic collapse	2.3.2 of this Appendix
Shortened stiffener element	Beam column buckling	2.3.3 of this Appendix
	Torsional buckling	2.3.4 of this Appendix
	Web local buckling of flanged profiles	2.3.5 of this Appendix
	Web local buckling of flat bars	2.3.6 of this Appendix
Shortened stiffened plate element	Plate buckling	2.3.7 of this Appendix

2.3.2 Elasto-plastic collapse of structural elements (Hard corner element)

The equation describing the load-end shortening curve σ-ε for the elasto-plastic collapse of structural elements composing the hull girder transverse section is to be obtained from the following formula.

$$\sigma = \Phi R_{eHA}$$

where: R_{eHA} — equivalent minimum yield stress, in N/mm^2, of the considered element, obtained by the following formula:

$$R_{eHA} = \frac{R_{eH_P}A_{p-net} + R_{eH_S}A_{s-net}}{A_{p-net} + A_{s-net}};$$

Φ — edge function, equal to:

$\Phi = -1$ for $\varepsilon < -1$;

$\Phi = \varepsilon$ for $-1 \le \varepsilon \le 1$;

$\Phi = 1$ for $\varepsilon > 1$;

ε — relative strain, equal to:

$$\varepsilon = \frac{\varepsilon_E}{\varepsilon_Y};$$

ε_E — element strain;

ε_Y — strain at yield stress in the element, equal to:

$$\varepsilon_Y = \frac{R_{eHA}}{E}.$$

2.3.3 Beam column buckling

The positive strain portion of the average stress – average strain curve σ_{CR1} - ε based on beam column buckling of plate-stiffener combinations is described according to the following:

$$\sigma_{CR1} = \Phi \sigma_{C1} \frac{A_{s-net} + A_{pE-net}}{A_{s-net} + A_{p-net}}$$

where: Φ — edge function, as defined in 2.3.2 of this Appendix;

σ_{C1}— critical stress, in N/mm^2, equal to:

$$\sigma_{C1} = \frac{\sigma_{E1}}{\varepsilon} \quad \text{for} \quad \sigma_{E1} \le \frac{R_{eHB}}{2}\varepsilon;$$

$$\sigma_{C1} = R_{eHB}\left(1 - \frac{R_{eHB}\varepsilon}{4\sigma_{E1}}\right) \quad \text{for} \quad \sigma_{E1} > \frac{R_{eHB}}{2}\varepsilon;$$

R_{eHB} — equivalent minimum yield stress, in N/mm^2, of the considered element, obtained by the following formula:

$$R_{eHB} = \frac{R_{eH_P}A_{pEI-net}\ell_{pE} + R_{eH_S}A_{s-net}\ell_{sE}}{A_{pEI-net}\ell_{pE} + A_{s-net}\ell_{sE}};$$

$A_{pEI\text{-}net}$ — effective area, in cm^2, equal to:

$$A_{pEI-net} = 10 b_{E1} t_{net};$$

l_{pE} — distance, in mm, measured from the neutral axis of the stiffener with attached plate of width b_{E1} to the bottom of the attached plate;

l_{sE} — distance, in mm, measured from the neutral axis of the stiffener with attached plate of width b_{E1} to the top of the stiffener;

ε — relative strain, as defined in 2.3.2 of this Appendix;

σ_{E1}— Euler column buckling stress, in N/mm^2, equal to:

$$\sigma_{E1} = \pi^2 E \frac{I_{E-net}}{A_{E-net}\ell^2} 10^{-4};$$

$I_{E\text{-}net}$ — net moment of inertia of stiffeners, in cm^4, with attached plate of width b_{E1};

$A_{E\text{-}net}$ — net area, in cm^2, of stiffeners with attached plating of width b_{E1};

b_{E1} — effective width corrected for relative strain, in m, of the attached plating, equal to:

$$b_{E1} = \frac{s}{\beta_E} \quad \text{for} \quad \beta_E > 1.0;$$

$$b_{E1} = s \quad \text{for} \quad \beta_E \le 1.0;$$

where: $\beta_E = 10^3 \frac{s}{t_{n50}} \sqrt{\frac{\varepsilon R_{eHp}}{E}}$;

$A_{pE\text{-net}}$ — net area, in cm^2, of attached plating of width b_E, equal to:

$$A_{pE-net} = 10 b_E t_{net};$$

b_E — effective width, in m, of the attached plating, equal to:

$$b_E = \left(\frac{2.25}{\beta_E} - \frac{1.25}{\beta_E^2}\right)s \quad \text{for} \quad \beta_E > 1.25;$$

$$b_E = s \quad \text{for} \quad \beta_E \le 1.25.$$

2.3.4 Torsional buckling

The load-end shortening curve σ_{CR2}-ε for the flexural-torsional buckling of stiffeners composing the hull girder transverse section is to be obtained according to the following formula:

$$\sigma_{CR2} = \Phi \frac{A_{s-net}\sigma_{C2} + A_{p-net}\sigma_{Cp}}{A_{s-net} + A_{p-net}}$$

where: Φ — edge function, as defined in 2.3.2 of this Appendix;

σ_{C2} — critical stress, in N/mm^2, equal to:

$$\sigma_{C2} = \frac{\sigma_{E2}}{\varepsilon} \quad \text{for} \quad \sigma_{E2} \le \frac{R_{eH_S}}{2}\varepsilon;$$

$$\sigma_{C2} = R_{eH_S}\left(1 - \frac{R_{eH_S}\varepsilon}{4\sigma_{E2}}\right) \quad \text{for} \quad \sigma_{E2} > \frac{R_{eH_S}}{2}\varepsilon;$$

ε— relative strain, as defined in 2.3.2 of this Appendix;

σ_{E2}— Euler column buckling stress, in N/mm^2, taken as σ_{ET} defined in 4.4.4 of Appendix 4 of this Chapter;

σ_{CP}— buckling stress of the attached plating, in N/mm^2, equal to:

$$\sigma_{CP} = \left(\frac{2.25}{\beta_E} - \frac{1.25}{\beta_E^2}\right) R_{eH_P} \qquad \text{for } \beta_E > 1.25$$

$$\sigma_{CP} = R_{eH_P} \qquad \text{for } \beta_E \le 1.25$$

β_E— coefficient, as defined in 2.3.3 of this Appendix.

2.3.5 Web local buckling of stiffeners made of flanged profiles

The load-end shortening curve σ_{CR3} - ε for the web local buckling of flanged stiffeners composing the hull girder transverse section is to be obtained from the following formula:

$$\sigma_{CR3} = \Phi \frac{10^3 b_E t_{net} R_{eH_P} + \left(h_{we} t_{w-net} + b_f t_{f-net}\right) R_{eH_S}}{10^3 s t_{net} + h_w t_{w-net} + b_f t_{f-net}}$$

where: Φ — edge function, as defined in 2.3.2 of this Appendix;

b_E — effective width, in m, of the attached plating, as defined in 2.3.3 of this Appendix;

h_{we} — effective height, in mm, of the web, equal to:

$$h_{we} = \left(\frac{2.25}{\beta_w} - \frac{1.25}{\beta_w^2}\right) h_w \qquad \text{for } \beta_w \ge 1.25;$$

$$h_{we} = h_w \qquad \text{for } \beta_w < 1.25;$$

β_w — $\beta_w = \frac{h_w}{t_{w-net}} \sqrt{\frac{\varepsilon R_{eH_S}}{E}}$;

ε— relative strain, as defined in 2.3.2 of this Appendix.

2.3.6 Web local buckling of stiffeners made of flat bars

The load-end shortening curve σ_{CR4}-ε for the web local buckling of flat bar stiffeners composing the hull girder transverse section is to be obtained from the following formula:

$$\sigma_{CR4} = \Phi \frac{A_{p-net}\sigma_{CP} + A_{s-net}\sigma_{C4}}{A_{p-net} + A_{s-net}}$$

where: Φ — edge function, as defined in 2.3.2 of this Appendix;

σ_{CP} — buckling stress of the attached plating, in N/mm^2, as defined in 2.3.4 of this Appendix;

σ_{C4} — critical stress, in N/mm^2, equal to:

$$\sigma_{C4} = \frac{\sigma_{E4}}{\varepsilon} \qquad \text{for } \sigma_{E4} \le \frac{R_{eH_S}}{2}\varepsilon;$$

$$\sigma_{C4} = R_{eH_S}\left(1 - \frac{R_{eH_S}\varepsilon}{4\sigma_{E4}}\right) \qquad \text{for } \sigma_{E4} > \frac{R_{eH_S}}{2}\varepsilon;$$

σ_{E4} — local Euler buckling stress, in N/mm^2, equal to:

$$\sigma_{E4} = 160000\left(\frac{t_{w-net}}{h_w}\right)^2;$$

ε— relative strain, as defined in 2.3.2 of this Appendix.

2.3.7 Plate buckling

The load-end shortening curve σ_{CR5}-ε for the buckling of transversely stiffened panels composing the hull girder transverse section is to be obtained from the following formula:

$$\sigma_{CR5} = min\begin{Bmatrix} R_{eH_P}\Phi \\ \Phi R_{eH_P}\left[\frac{s}{\ell}\left(\frac{2.25}{\beta_E} - \frac{1.25}{\beta_E^2}\right) + 0.1\left(1 - \frac{s}{\ell}\right)\left(1 + \frac{1}{\beta_E^2}\right)^2\right] \end{Bmatrix}$$

where: Φ — edge function, as defined in 2.3.2 of this Appendix;

β_E — coefficient as defined in 2.3.3 of this Appendix;

s — plate breadth, in m, taken as the spacing between the stiffeners;

l— longer side of the plate, in m.

3 Alternative Methods

3.1 General

3.1.1 Application of alternative methods is to be agreed by CCS prior to commencement. Documentation of the analysis methodology and detailed comparison of its results are to be submitted for review and acceptance. The use of such methods may require the partial safety factors to be recalibrated.

3.1.2 The bending moment-curvature relationship, M-χ, may be established by alternative methods. Such models are to consider all the relevant effects important to the non-linear response with due considerations of:

(a) non-linear geometrical behavior;
(b) inelastic material behavior;
(c) geometrical imperfections and residual stresses (geometrical out-of-flatness of plate and stiffeners);
(d) simultaneously acting loads:
- bi-axial compression;
- bi-axial tension;
- shear and lateral pressure;

(e) boundary conditions;
(f) interactions between buckling modes;
(g) interactions between structural elements such as plates, stiffeners, girders, etc.;
(h) post-buckling capacity;
(i) overstressed elements on the compression side of hull girder cross section possibly leading to local permanent sets/buckle damages in plating, stiffeners, etc. (double bottom effects or similar).

3.2 Non-linear finite element analysis

3.2.1 Advanced non-linear finite element analyses models may be used for the assessment of the hull girder ultimate capacity. Such models are to consider the relevant effects important to the non-linear responses with due consideration of the items listed in 3.1.2.

3.2.2 Particular attention is to be given to modelling the shape and size of geometrical imperfections. It is to be ensured that the shape and size of geometrical imperfections trigger the most critical failure modes.

CHAPTER 8 BULK CARRIERS

Section 1 GENERAL PROVISIONS

8.1.1 Application

8.1.1.1 Bulk carriers are ships provided with single deck, double bottom, topside tank and hopper tank, and intended primarily to carry dry cargo in bulk, not including ore carriers.

8.1.1.2 This Chapter applies to bulk carriers as defined in 8.1.1.1 above, with the exception of those complying with 8.1.1.3 below.

8.1.1.3 CSR bulk carriers are to comply with the requirements in PART NINE of the Rules.

8.1.1.4 Those not covered in this Chapter are to comply with the relevant requirements of Chapter 2 of this PART.

8.1.2 Class notations

8.1.2.1 Bulk carriers complying with the provisions of this Chapter are eligible for one of the following notations:

(1) “Bulk Carrier” for bulk carriers;

(2) “Bulk Carrier, Strengthened for Heavy Cargoes” for bulk carriers strengthened for heavy cargoes;

(3) “Bulk Carrier, Strengthened for Heavy Cargoes, Holds a,b,… may be empty” for bulk carriers strengthened for heavy cargoes with specified or alternate holds empty.

8.1.2.2 Bulk carriers complying with the provisions of this Chapter, of which all cargo holds are bounded by double side skin construction of not less than 1000 mm breadth between the inner shell and the outer shell, are to be assigned one of the following notations:

(1) “Bulk Carrier, Double Side Skin” for double side skin bulk carriers;

(2) “Bulk Carrier, Double Side Skin, Strengthened for Heavy Cargoes” for double side skin bulk carriers strengthened for heavy cargoes;

(3) “Bulk Carrier, Double Side Skin, Strengthened for Heavy Cargoes, Holds a,b,… may be empty” for double side skin bulk carriers strengthened for heavy cargoes with specified or alternate holds empty.

8.1.2.3 Typical bulk carriers of 150 m or over in length and constructed with single deck, double bottom, topside tanks and hopper tanks in the cargo hold region and of single side skin or double side skin construction are to be assigned one of the following harmonized notations: BC-A; BC-B; BC-C. The harmonized notations and relevant design loading conditions are to comply with the requirements of Section 12 of this Chapter.

8.1.2.4 Bulk carriers with self-unloading function complying with the requirements of this Chapter are assigned the class notation “Self-Unloading Bulk Carrier”.

8.1.3 Plans and documents

8.1.3.1 In addition to the plans and documents specified in Section 1, Chapter 2 of this PART, the following are to be submitted for information:

(1) the maximum pressure head in service on tanks and details of any double bottom tanks interconnected with hopper tanks, ballast tanks within double side skin and topside tanks;

(2) details of the proposed depths of any partial fillings where water ballast or liquid cargo is intended to be carried in the holds.

8.1.4 Direct strength calculation and fatigue strength assessment for hull structure

8.1.4.1 For bulk carriers of 150 m or over in length, direct calculation is to be carried out for the strength of primary structural members (both longitudinal and transverse) within cargo area in accordance with the requirements of Appendix 1 of this Chapter.

8.1.4.2 For bulk carriers of 150 m or over in length, the fatigue strength check is to be carried out for the following structural members in the cargo area in accordance with CCS Guidelines for Fatigue Strength of Ship Structure:

(1) connections of longitudinals (bottom, side, deck and inner shell) to transverse web frames;

(2) connections of longitudinals (bottom, side, deck and inner shell) to transverse bulkheads;

(3) connections of hopper tanks or inner shell to inner bottoms;

(4) connections of inner bottoms to lower stool side plates;

(5) connections of corrugated transverse bulkheads to lower stool top plates;

(6) connections of corrugated transverse bulkheads to upper stool sloping plates;

(7) connections of frames to top side tanks and hopper tanks of single hull bulk carriers.

8.1.5 Protection of cargo holds from loading/discharge equipment

8.1.5.1 In bulk carriers of 150 m in load line length L_L and upwards, carrying solid bulk cargoes having a density of 1,000 kg/m^3 and above, cargo holds are to be protected from loading/discharge equipment as follows:
(1) structural strengthening is to be provided and the Grab notation assigned in accordance with Section 23, Chapter 2 of this PART;
(2) wire rope grooving in way of cargo holds openings is to be prevented by fitting suitable protection such as half-round bar on the hatch side girders (i.e. upper portion of topside tank plates), hatch end beams or upper portion of hatch coamings.

Section 2 BOTTOM STRUCTURES

8.2.1 General requirements

8.2.1.1 For bulk carriers intended to be assigned the class notation of Bulk Carrier, Strengthened for Heavy Cargoes, the bottom structures are to comply with the provisions in Section 22, Chapter 2 of this PART.
8.2.1.2 Where the double bottom tanks are interconnected with hopper side tanks, the scantlings are to satisfy the requirements of Section 13, Chapter 2 of this PART for deep tanks.
8.2.1.3 For bulk carries of 150 m and over in length, the thickness of solid floors are determined by direction calculations, but the minimum thickness is not be less than that obtained from the following formula:

$$t_{\min} = \max\left(0.6\sqrt{L} + 3,\quad 12\right) \qquad \text{mm}$$

where: L—length of ship, in m, to be taken not greater than 300 m in calculation.
8.2.1.4 For bulk carries of 150 m and over in length, the thickness of watertight solid floors is also to comply with the requirements for deep tanks in Section 13, Chapter 2, in addition to complying with the requirements of 8.2.1.3.
8.2.1.5 For longitudinally framed double bottom, where it is verified by direct calculation, a maximum of 1.5 times frame spacing may be accepted for the spacing between bottom and inner bottom stiffening members within the duct keel.
8.2.1.6 For bulk carriers of less than 150 m in length intended to be assigned the class notation “Bulk Carrier, Strengthened for Heavy Cargoes, Hold Nos… may be Empty”, the bottom structures are to comply with the requirements of this Section and in addition, the direct calculation is to be carried out for the strength of primary members of double bottom (both longitudinal and transverse) in accordance with the requirements of Appendix 1 of this Chapter.

Section 3 SIDE FRAMING

8.3.1 Application

8.3.1.1 This Section applies to side structures of cargo holds bounded by the side shell only of bulk carriers constructed with single deck, topside tanks and hopper tanks in cargo spaces intended primarily to carry dry cargo in bulk.

8.3.2 Side shell plating

8.3.2.1 The thickness of the side shell plating is to be determined according to the requirements in Chapter 2 of this PART. The thickness t of the shell plating between hopper and topside tanks within the cargo area is not to be less than that obtained from the following formula:

$$t = \sqrt{L} \qquad \text{mm}$$

where: L — length of ship, in m.

8.3.3 Main Frames

8.3.3.1 For bulk carriers of 190 m and over in length, the main frames within the cargo area are to be integral with their upper and lower brackets and symmetrical in their transverse section.
8.3.3.2 In bulk carriers less than 190 m in length, mild steel main frames within the cargo area may be

fitted with separate brackets and asymmetric in their transverse section.

8.3.3.3 The minimum web thickness of main frames is to be obtained from the following formula:

$$t = 7.0 + 0.03L \quad \text{mm}$$

where: L — length of ship, in m, need not be taken greater than 200 m.

8.3.3.4 The section modulus W of the main frames in holds is not to be less than that obtained from the following formula:

$$W = 5.8\, sh_1 l^2 K \quad \text{cm}^3$$

where: s — spacing of frames, in m;

K — material factor;

h_1 — vertical distance, in m, measured between the midpoint of the span of frames and a point situated at $0.01L + 0.8$ above the load waterline, see Figure 8.3.3.4, where: L — the length of ship, in m;

l — span of frame, in m, i.e. the distance measured between the intersection of sloping plating with the side shell; for $l < 0.25D$, to be taken as $0.25D$ (D being moulded depth, in m).

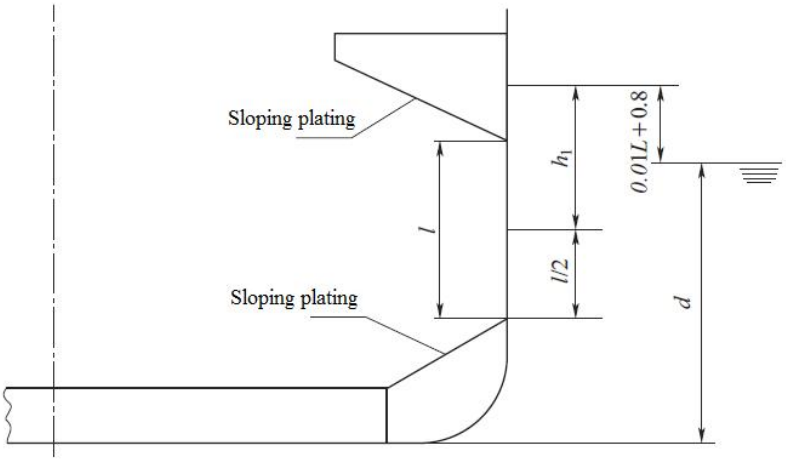

Figure 8.3.3.4

8.3.3.5 The web depth to thickness ratio of main frames is not to exceed the following values:

$60\sqrt{K}$ for symmetrically flanged frames

$50\sqrt{K}$ for unsymmetrically flanged frames

where: K — material factor.

8.3.3.6 The maximum breadth of the frame flange outstand is not to exceed $10\sqrt{K}$ times the thickness of the flange.

8.3.3.7 The frame flange is to be radiused at the connection with the end brackets (see Figure 8.3.3.7), with the radius of curvature being not less than that obtained by the following formula:

$$r = \frac{0.4 b_f^2}{t_f} \quad \text{mm}$$

where: b_f — face plate width of lower or upper bracket, in mm;

t_f — face plate thickness of lower or upper bracket, in mm.

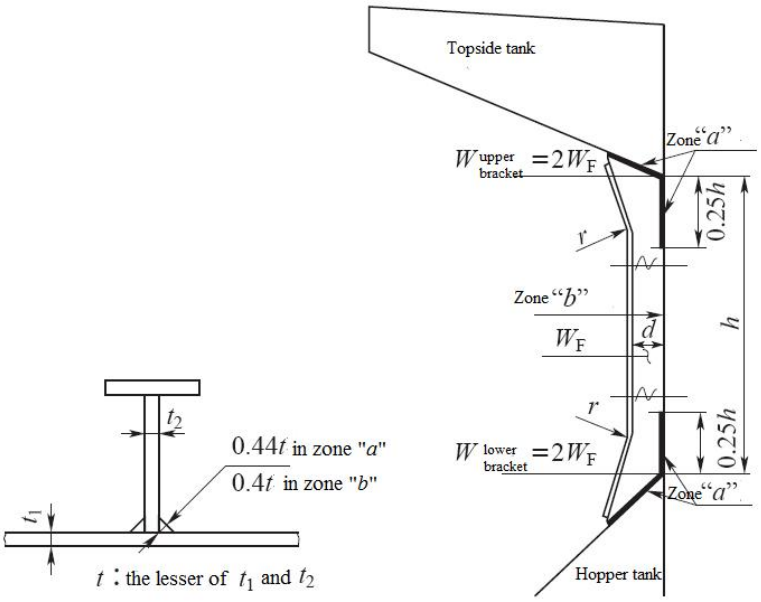

Figure 8.3.3.7

8.3.4 Lower and upper brackets of main frames

8.3.4.1 The thickness of the lower brackets is not to be less than that of the frame webs, nor to be less than that derived from 8.3.3.3 of this Section plus 2 mm.

8.3.4.2 The thickness of the upper brackets is not to be less than that of the frame webs.

8.3.4.3 The dimensions of the lower and upper brackets are not to be less than those shown in Figure 8.3.4.3.

8.3.4.4 The section modulus of the frame and the bracket or integral bracket, at the locations shown in Figure 8.3.3.7, is not to be less than twice the value obtained as per 8.3.3.4 of this Section.

8.3.4.5 The structural continuity of the upper and lower end connections of the frames is to be ensured by connecting brackets, as shown in Figure 8.3.4.5, within topside and hopper tanks. The brackets are in general to be stiffened against buckling in accordance with Figure 8.3.4.5.

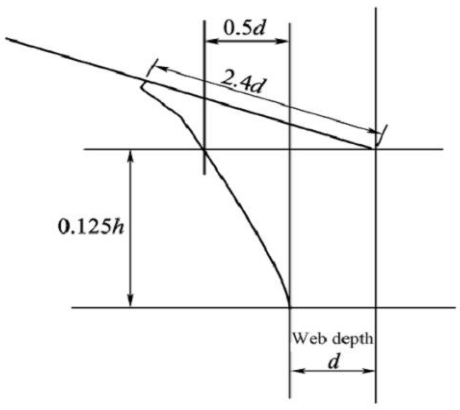

Figure 8.3.4.3

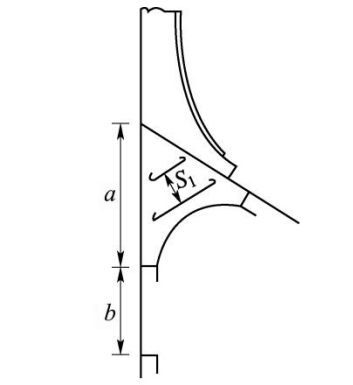

Figure 8.3.4.5

8.3.4.6 Upper and lower brackets are to be arranged at their ends with soft toes as shown in Figure 1.2.7.6 of Section 2, Chapter 1 of this PART.

8.3.4.7 The section moduli of the side longitudinals, topside tank sloping plate longitudinals and hopper tank sloping plate longitudinals which support the connecting brackets in 8.3.4.5 are to be determined with the span taken between transverses. When the arrangement of the upper and lower brackets of the frames and the connecting brackets is different from this Section, the side longitudinals, topside tank sloping plate longitudinals and hopper tank sloping plate longitudinals are to effectively support the connecting brackets, subject to agreement of CCS.

8.3.5 Strengthening of side structures in the foremost hold

8.3.5.1 The minimum web thickness of main frames is to be 1.15 times that required in 8.3.3.3 of this Section.
8.3.5.2 The scantlings of the main frames immediately adjacent to the collision bulkhead are to be properly increased in order to prevent deformation of the shell plating. As an alternative, side stingers or perforated platforms in the forepeak may be extended to the foremost frame of the foremost hold. The extension is to be provided with an adequate shear-resistant area for connection with the frame.
8.3.5.3 Where main frames of the foremost hold are asymmetrical in their transverse section, tripping brackets are to be fitted close to the mid-span of every second frame, as shown in Figure 8.3.5.3.

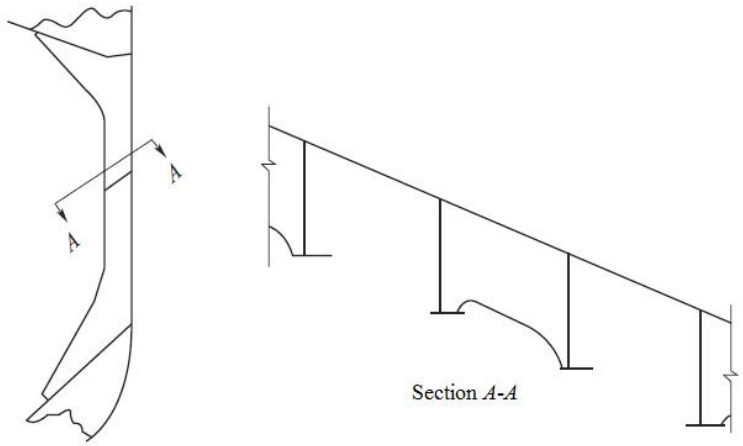

Figure 8.3.5.3

8.3.6 Weld connections of frames and brackets to side shell and sloping plating

8.3.6.1 Double continuous welding is to be adopted for the fillet-weld connections of frames and brackets to side shell, topside and hopper tank sloping plating and web to face plates. For this purpose, the weld throat is to be (see Figure 8.3.3.7):

0.44 t in zone “a”

0.4 t in zone “b”

where: t — the thinner of the two connected members, in mm.

8.3.6.2 Where the hull form is such that an effective fillet weld cannot be made, edge preparation of the web of the frame and bracket may be required, in order to ensure the required efficiency of the weld connection.

Section 4 WATERTIGHT BULKHEADS

8.4.1 General requirements

8.4.1.1 Watertight bulkheads are to comply with the requirements of Section 12, Chapter 2 of this PART. The transverse bulkheads forming boundaries of ballast holds are also to comply with the requirements of Section 13, Chapter 2 of this PART for deep tank bulkheads.
8.4.1.2 Stools, if fitted at the top and bottom of the corrugated watertight bulkhead, are to comply with the following requirements:
(1) The sloping plating of lower stools is to be fitted on solid floors. The thickness of the sloping plating is not to be less than that of the bulkhead plating required in Section 12, Chapter 2 of this PART and in addition, is not to be less than that required in 8.5.2.1 of this Chapter for the sloping plating of hopper tanks.
(2) Where stiffeners are fitted on the sloping plating of lower stools, their section modulus is not to be less than that required in 8.5.3.1 of this Chapter for the longitudinals on the sloping plating of hopper tanks.
(3) Diaphragms are to be fitted in lower stools in way of bottom girders, having the same thickness as that of the inner bottom longitudinal girders.
(4) The scantlings of upper stools are not to be less than those required in Section 12, Chapter 2 of this PART.
(5) Stool structures situated in liquid tanks are also to comply with the requirements of Section 13, Chapter 2 of this PART for deep tanks.

Section 5 HOPPER TANKS

8.5.1 General requirements

8.5.1.1 Watertight bulkheads are to be fitted, as far as practicable, in the hopper tanks in way of the watertight bulkheads in holds. Otherwise wash bulkheads are to be fitted.

8.5.1.2 Consideration is to be given to the structural continuity of both ends of hopper tanks.

8.5.1.3 For the calculation of scantlings of hopper tank structural members, the tank top is the highest point of the topside tank where hopper tanks are interconnected with topside tanks, or the highest point of the ballast tank within double side skin where hopper tanks are interconnected with such ballast tanks.

8.5.1.4 The requirements of this Section apply to hopper tanks framed longitudinally.

8.5.2 Sloping plating

8.5.2.1 The thickness of the sloping plating is not to be less than that of inner bottom plating as required in Section 6, Chapter 2 of this PART. For ships intended to be assigned the class notation of Bulk Carrier, Strengthened for Heavy Cargoes, the sloping plating is to be increased in thickness in accordance with the requirements of 2.22.3.4 of this PART, but this increase may be gradually tapered from the intersection of sloping plating and inner bottom plating to nil at the top corner of the tank. Where hopper tanks are interconnected with topside tanks or form boundaries of ballast holds, the thickness of the sloping plating is not to be less than that required in Section 13, Chapter 2 of this PART for deep tanks.

8.5.2.2 Where the hopper tanks are fitted with watertight side bulkheads, the thickness t of the side bulkhead plating is not to be less than that obtained from the following formula:

$$t = 4s\sqrt{hK} + 2.5 \quad \text{mm}$$

where: s — spacing of stiffeners, in m;

h — vertical distance, in m, measured from the lower edge of strake to the tank top or half of the vertical distance to the top of the overflow, whichever is the greater;

K — material factor.

8.5.3 Longitudinals

8.5.3.1 The section modulus W of the sloping plating longitudinals is not to be less than that of the inner bottom longitudinals as required in Section 6, Chapter 2 of this PART.

If the class notation of Strengthened for Heavy Cargoes is intended, the section modulus is nor to be less than that obtained from the following formula:

$$W = 8.5Hsl^2K/\gamma \quad \text{cm}^3$$

where: γ — see Section 22, Chapter 2 of this PART;

H — vertical distance, in m, measured from longitudinal to the lower edge of the sloping plating of topside tanks; where no topside tank is provided, measured from longitudinal to upper deck;

s — spacing of longitudinals, in m;

l — span of longitudinal, in m;

K — material factor.

Where hopper tanks are interconnected with topside tanks or form boundaries of ballast holds, the section modulus W of the sloping plating longitudinals is not to be less than:

$$W = 9shl^2K \quad \text{cm}^3$$

where: s, l, K— same as defined above;

h — vertical distance, in m, measured from the longitudinal to the tank top, or half of the vertical distance to the top of the overflow, whichever is the greater.

8.5.3.2 The section modulus W of side and bilge longitudinals in hopper tanks is not to be less than that required in Section 7, Chapter 2 of this PART.

8.5.3.3 The section modulus W of bottom longitudinals in hopper tanks is not to be less than that required in Section 6, Chapter 2 of this PART.

8.5.4 Transverse supporting structural members

8.5.4.1 Transverse structural members supporting the longitudinals of the hopper tanks are to be fitted in way of the floors within holds.

8.5.4.2 The section modulus W and the section moment of inertia I of bottom transverses and side shell transverses are not to be less than those obtained from the following formulae:

$$W = 12Shl^2K \quad \text{cm}^3$$

$$I = 2.5Wl/K \quad \text{cm}^4$$

where: S — spacing of bottom or side shell transverses, in m;
l — span of bottom or side shell transverse, in m;
h — vertical distance, in m, from the mid-point of span to the upper deck at side;
K — material factor.

8.5.4.3 The section modulus W and the section moment of inertial I of sloping plating transverses are not to be less than those obtained from the following formulae:

$$W = 12Shl^2K \quad \text{cm}^3$$
$$I = 2.5Wl/K \quad \text{cm}^4$$

where: S — spacing of transverses, in m;
l — span of transverse, in m;
h — vertical distance, in m, measured from the mid-point of span to the tank top of or half of the vertical distance to the top of the overflow, whichever is the greater;
K — material factor.

If the class notation of Strengthened for Heavy Cargoes is intended, the section modulus W and the section moment of inertial I of sloping plating transverses are not to be less than those obtained from the following formulae:

$$W = 6.6HSl^2K/\gamma \quad \text{cm}^3$$
$$I = 1.8Wl/K \quad \text{cm}^4$$

where: γ — see Section 22, Chapter 2 of this PART;
H — vertical distance, in m, measured from the mid-point of span to the lower edge of the sloping plating of the topside tank;
S — spacing of transverses, in m;
l — span of transverse, in m;
K — material factor.

8.5.4.4 Bottom transverses, side shell transverses and sloping plating transverses are to be effectively connected one another. Longitudinals are to be continuous through the bottom and side shell transverses and the sloping plating transverses, and are to be welded to their web plates. The web depth of primary supporting members is not to be less than 2.5 times the depth of the slot for the passage of longitudinals, and the web is to be suitably fitted with stiffeners between sloping plating longitudinals and bottom longitudinals or side longitudinals in compliance with the same requirements in 2.6.11.2 of Section 6, Chapter 2 of this PART. Brackets connecting the face plate of primary supporting members and the longitudinals are to be fitted at least at alternate longitudinals, and the thickness of brackets is to be the same as that of the web of the primary supporting members.

8.5.4.5 Where non-watertight transverse webs are provided in lieu of the above-mentioned bottom transverses, side shell transverses and slopping plating transverses, the thickness and stiffeners of such webs are to meet the requirements of 8.5.6.

8.5.4.6 Where the side shell in way of cargo holds is framed transversely, brackets are to be fitted above the hopper tank at every frame. The thickness of the brackets is to be the same as the web depth in way of the side shell transverse ring in the hopper tank, and the length of the brackets, measured along the sloping plating and the side shell, is not to be less than that of the free edge of the lower brackets of the hold main frames. These brackets are to be welded to the adjacent longitudinals. Buckling-restrained stiffeners are to be fitted to the brackets. The direction of stiffeners is shown in Figure 8.3.4.5 of this Chapter and their sectional scantlings are to be the same as that of the stiffeners on bottom transverses.

8.5.5 Watertight bulkheads

8.5.5.1 The thickness t of watertight bulkhead plating is not to be less than that obtained from the following formula:

$$t = 4s\sqrt{hK} + 2.5 \quad \text{mm}$$

where: s — spacing of stiffeners, in m;
K — material factor;
h — vertical distance, in m, measured from the lower edge of strake to the tank top or half of the vertical distance to the top of the overflow, whichever is the greater.

8.5.5.2 The section modulus W of stiffeners on the watertight bulkheads is not to be less than that obtained from the following formula:

$$W = 8.2shl^2K \quad \text{cm}^3$$

where: s — spacing of stiffeners, in m;
h — vertical distance, in m, measured from the mid-point of span of the stiffeners to the tank top or half of the vertical distance to the top of the overflow, whichever is the greater;
l — span of stiffener, in m;

K — material factor.

Stiffeners are to be bracketed at both ends.

8.5.6 Non-watertight bulkheads and wash bulkheads

8.5.6.1 The plating thickness t of non-watertight or wash bulkheads is not to be less than that obtained from the following formula and not to be less than 8 mm:

$$t = 12s \quad \text{mm}$$

where: s — spacing of stiffeners, in m.

8.5.6.2 The section modulus of the stiffeners on the non-watertight or wash bulkheads is not to be less than 50% of that derived from 8.5.5.2 of this Section. Stiffeners are to be bracketed at both ends.

Section 6 TOPSIDE TANKS

8.6.1 General requirements

8.6.1.1 Watertight bulkheads are to be fitted, as far as practicable, in the topside tanks in way of the watertight bulkheads in holds. Otherwise, wash bulkheads are to be fitted.

8.6.1.2 Consideration is to be given to the structural continuity of both ends of topside tanks.

8.6.2 Sloping plating and vertical side plating

8.6.2.1 The thickness t of the sloping plating is not to be less than that obtained from the following formula, and not to be less than 8 mm:

$$t = 4s\sqrt{hK} + 2.5 \quad \text{mm}$$

$$t = 12s/\sqrt{K} \quad \text{mm}$$

where: s — spacing of longitudinals, in m;

K — material factor;

h = $h_1 \cos\theta + b_1 \sin\theta$, or vertical distance, in m, measured from the lower edge of strake to the tank top or half of the vertical distance to the top of the overflow, whichever is the greater;

h_1 — vertical distance, in m, measured from the lower edge of strake to the highest point of the topside tank;

b_1 — horizontal distance, in m, measured from the lower edge of strake to the highest point of the topside tank at either side, whichever is the greater;

θ = 30°.

The thickness of the lowest strake is to be increased by 1 mm above that obtained from the above formula.

8.6.2.2 The thickness of the vertical side plating fitted in line with hatch side coamings and of the top strake of the topside tank sloping plating is not to be less than 60% of that of the deck plate outside the line of openings, nor to be less than 18s (s being the spacing of longitudinals, in m). Brackets, spaced not more than 2 frame spaces apart, are to be fitted at the vertical side plating, and extended to deck and sloping plating longitudinals and welded to them.

8.6.3 Longitudinals

8.6.3.1 The section modulus W of deck, sloping plating and side longitudinals are not to be less than that of the following formula:

$$W = 10shl^2K \quad \text{cm}^3$$

where: s — spacing of longitudinals, in m;

l — span of longitudinal, in m;

K — material factor;

h = $h_1 \cos\theta + b_1 \sin\theta$, or vertical distance, in m, measured from the longitudinal to the tank top or half of the vertical distance to the top of the overflow, whichever is the greater, and not to be less than 1.5 m;

h_1 — vertical distance, in m, measured from the longitudinal to the highest point of the topside tank;

b_1 — horizontal distance, in m, measured from the longitudinal to the highest point of the topside tank at either side, whichever is the greater;

θ = 30°.

8.6.3.2 The scantlings of deck and side longitudinals are also to comply with the relevant requirements of Chapter 2 of this PART.

8.6.4 Transverse supporting structural members

8.6.4.1 The section modulus W and the section moment of inertia I of the deck, sloping plating and side shell transverses supporting the longitudinals are not to be less than those obtained from the following formulae:

$$W = 7.5Shl^2K \quad \text{cm}^3$$
$$I = 2.5Wl/K \quad \text{cm}^4$$

where: S — spacing of deck or side shell transverses, in m;
l — span of deck or side shell transverse, in m;
K — material factor;
h = $h_1 \cos\theta + b_1 \sin\theta$, or vertical distance, in m, measured from the mid-point of span to the tank top, or half of the vertical distance to the top of the overflow, whichever is the greater, and not to be less than 1.5 m;
h_1 — vertical distance, in m, measured from the mid-point of span to the highest point of the topside tank;
b_1 — horizontal distance, in m, measured from the mid-point of span to the highest point of the topside tank at either side, whichever is the greater;
θ = 30°.

8.6.4.2 The scantlings of deck or side shell transverses are not to be less than as required in Chapter 2 of this PART. Their web depth is not to be less than twice the depth of the slot for the passage of longitudinals. The web thickness is not to be less than 1% of its depth plus 4 mm.

8.6.4.3 The deck, sloping plating and side shell transverses are to be connected one another by brackets.

8.6.4.4 The longitudinals are to be continuous through the deck, sloping plating and side shell transverses, and are to be welded to their web plates. Brackets connecting the face plate of primary supporting members and the longitudinals are to be fitted at least at alternate longitudinals, and the thickness of brackets is to be the same as that of the web of the primary supporting members.

8.6.4.5 Primary transverse members supporting the longitudinals in topside tanks are, in general, to be spaced not more than 3.6 m apart for ships equal to or less than 100 m in length, and not more than $0.006L$ + 3.0 m apart for ships more than 100 m in length. Larger spacing may be accepted where the evaluation is carried out by means of direct strength calculation in accordance with the requirements of Appendix 1 of this Chapter.

8.6.4.6 Where non-watertight transverse webs are provided in lieu of the above-mentioned deck transverses, side shell transverses and slopping plating transverses, the thickness and stiffeners of such webs are to meet the requirements of 8.6.7.

8.6.4.7 Where the side shell in way of cargo holds is framed transversely, brackets are to be fitted below the topside tank at every frame. The thickness of the brackets is to be the same as the web depth in way of the side shell transverse ring in the topside tank, and these brackets are to be extended and welded to the adjacent longitudinals along the side shell and sloping plating. The brackets are to be in line with the upper brackets of the hold main frames.

8.6.4.8 Where a rounded gunwale is adopted, a bracket is to be fitted in way of the rounded gunwale approximately halfway between transverses, extending and welded to the adjacent deck and shell longitudinals.

8.6.4.9 Transverse supporting members are to be arranged in topside tanks in line with hatch end coamings.

8.6.5 Shell framing

8.6.5.1 Where the side shell is framed transversely, the section modulus W of the frames is not to be less than that obtained from the following formula:

$$W = 10shl^2K \quad \text{cm}^3$$

where: s — spacing of frames, in m;
l — span of frame, in m;
K — material factor;
h = $h_1 \cos\theta + b_1 \sin\theta$, or vertical distance, in m, measured from the mid-point of span to the tank top, or half of the vertical distance to the top of the overflow, whichever is the greater;
h_1 — vertical distance, in m, measured from the mid-point of span to the highest point of the topside tank;
b_1 — horizontal distance, in m, measured from the mid-point of span to the highest point of the topside tank at either side, whichever is the greater;
θ = 30°.

Frames are also to comply with the requirements of 2.13.6.1 of this PART.
8.6.5.2 Bracket are to be fitted at both ends of frames, extended and welded to the adjacent deck and sloping plating longitudinals. The thickness of brackets is to be the same as that of the upper brackets of hold main frames.

8.6.6 Watertight bulkheads

8.6.6.1 The thickness t of the watertight bulkheads is not to be less than that obtained from the following formula, and not to be less than 8 mm:

$$t = 4s\sqrt{hK} + 2.5 \quad \text{mm}$$

$$t = 12s/\sqrt{K} \quad \text{mm}$$

where: s — spacing of stiffeners, in m;
K — material factor;
h = $h_1 \cos\theta + b_1 \sin\theta$, or vertical distance, in m, measured from the lower edge of strake to the tank top, or half of the vertical distance to the top of the overflow, whichever is the greater;
h_1 — vertical distance, in m, measured from the lower edge of strake to the highest point of the topside tank;
b_1 — horizontal distance, in m, measured from the lower edge of strake to the highest point of the topside tank at either side, whichever is the greater;
θ = 30°.
The thickness of the lowest strake is to be increased by 1 mm above that derived from above.
8.6.6.2 The section modulus W of stiffeners on the watertight bulkheads is not to be less than that obtained from the following formula:

$$W = 10shl^2K \quad \text{cm}^3$$

where: s — spacing of stiffeners, in m;
l — span of stiffener, in m;
K — material factor;
h = $h_1 \cos\theta + b_1 \sin\theta$, or vertical distance, in m, measured from the mid-point of span to the tank top, or half of the vertical distance to the top of the overflow, whichever is the greater;
h_1 — the vertical distance, in m, measured from the mid-point of span to the highest point of the topside tank;
b_1 — horizontal distance, in m, measured from the mid-point of span to the highest point of the topside tank at either side, whichever is the greater;
θ = 30°.
The stiffeners are to be bracketed at both ends.

8.6.7 Non-watertight and wash bulkheads

8.6.7.1 The plating thickness t of non-watertight or wash bulkheads is to be in compliance with 8.5.6.1 of this Chapter.
8.6.7.2 The section modulus of the stiffeners on the non-watertight or wash bulkheads is not to be less than 50% of that derived from 8.6.6.2 of this Section. The stiffeners are to be bracketed at both ends.

Section 7 ADDITIONAL REQUIREMENTS FOR LOADING MANUALS AND LOADING INSTRUMENTS

8.7.1 Application

8.7.1.1 This Section applies to bulk carriers, ore carriers and combination carriers of 150 m and over in length.
8.7.1.2 Hold mass curves are calculated and drawn in accordance with Appendix 2 of this Chapter.

8.7.2 Loading manuals

8.7.2.1 The loading manual is to describe:
(1) the loading condition on which the design of the ship has been based, including still water bending moments and shear forces and where applicable, the results of the calculations of torsional loads;
(2) permissible limits of still water bending moments and shear forces;
(3) envelope results and still water bending moments and shear forces in the hold flooded condition according to Section 8 of this Chapter as applicable;

(4) the cargo hold(s) or combination of cargo holds that may be empty at full draught. If no cargo hold is allowed to be empty at full draught, this is to be clearly stated in the loading manual;
(5) maximum allowable and minimum required mass of cargo and double bottom contents of each hold as a function of the draught at mid-hold position;
(6) maximum allowable and minimum required mass of cargo and double bottom contents of any two adjacent holds as a function of the mean draught in way of these holds. This mean draught is to be calculated by averaging the draught at the two mid-hold positions;
(7) maximum allowable tank top loading together with specification of the nature of the cargo for cargoes other than bulk cargoes;
(8) maximum allowable load on deck and hatch covers. If the vessel is not approved to carry load on deck or hatch covers, this is to be clearly stated in the loading manual;
(9) the maximum rate of ballast change together with the advice that a load plan is to be agreed with the terminal on the achievable rates of change of ballast.

8.7.2.2 Conditions of approval of loading manuals

In addition to the requirements given in 2.2.8.11 of this PART, the following conditions, subdivided into departure and arrival conditions as appropriate, are to be included in the loading manual:
(1) Alternate light and heavy cargo loading conditions at maximum draught, where applicable;
(2) Homogeneous light and heavy cargo loading conditions at maximum draught;
(3) Ballast conditions. For bulk carriers having ballast holds adjacent to topside wing, hopper and double bottom tanks, it is to be strengthwise acceptable that the ballast holds are filled when the topside wing, hopper and double bottom tanks are empty;
(4) Short voyage conditions where the ship is to be loaded to maximum draught but with limited amount of bunkers, where applicable;
(5) Multiple port loading/unloading conditions, where applicable;
(6) Deck cargo conditions, where applicable;
(7) Typical loading sequences where the ship is loaded from commencement of cargo loading to reaching full deadweight capacity, for homogeneous conditions, relevant part load conditions and alternate conditions where applicable. Typical unloading sequences for these conditions are also to be included. The typical loading/unloading sequences are to be developed not to exceed applicable strength limitations. These sequences are to be developed paying due attention to loading/unloading rate and deballasting capacity. Table 8.7.2.2 shows an example of the Sheet of Loading Sequences for guidance;
(8) Typical sequences for exchange of ballast water at sea, where applicable.

Typical Sheet of Loading Sequences for Guidance

h = height of hold from inner bottom to top of coaming (m)
T = draught (m)

Approved by:

Place, date, stamp and sign

8.7.3 Loading instrument

8.7.3.1 A loading instrument with the display function is an approved digital system as defined in 2.2.8.4 of this PART. In addition to the requirements in 2.2.8.4 of this PART, it is to ascertain as appropriate that:

(1) the mass of cargo and double bottom contents in way of each hold as a function of the draught at mid-hold position;

(2) the mass of cargo and double bottom contents of any two adjacent holds as a function of the mean draught in way of these holds;

(3) the still water bending moment and shear forces in the hold flooded conditions according to Section 8 of this Chapter are permissible.

8.7.3.2 Conditions of approval of loading instruments

The loading instrument is subject to approval. In addition to the requirements given in 2.2.8.12 of this PART, the approval is to include as applicable:

(1) acceptance of hull girder bending moment limits for all read-out points;

(2) acceptance of hull girder shear force limits for all read-out points;

(3) acceptance of limits for mass of cargo and double bottom contents of each hold as a function of draught;

(4) acceptance of limits for mass of cargo and double bottom contents in any two adjacent holds as a function of draught.

8.7.4 Guidance for loading/unloading sequences

8.7.4.1 Where a typical loading/unloading sequences manual is prepared, due attention is to be given to the loading/unloading rate, ballasting/deballasting capacity and applicable strength limitations.

8.7.4.2 The typical loading/unloading sequence is to be prepared and submitted for approval by shipyard.

8.7.4.3 The relevant contents of typical loading/unloading sequences are to include:

(1) alternate light and heavy cargo loading conditions;

(2) homogeneous light and heavy cargo loading conditions;

(3) short voyage conditions where the ship is to be loaded to maximum draught but with limited amount of bunkers;

(4) multi-port loading/unloading conditions;

(5) deck cargo condition;

(6) alt-block loading condition.

8.7.4.4 The loading/unloading sequences may be for a specific port or a typical sequence.

8.7.4.5 The loading/unloading sequences of the selected loading condition are to be compiled one step by one step from commencement of cargo loading to reaching full deadweight capacity. A step is finished when the loading equipment is moved to another cargo hold. File is to be submitted to CCS for each step. In addition to the longitudinal strength, the local strength of each cargo hold is to be taken into consideration.

8.7.4.6 Each loading condition is to include the summary of all steps. It is to focus on the key information of each step, such as:

(1) the capacity of cargoes in each cargo hold for different steps;

(2) the volume of discharged ballast water for each ballast tank in different steps;

(3) the maximum still water bending moment and shear force when each step is finished;

(4) the trim and draught of ship when each step is finished.

Section 8 OVERALL LONGITUDINAL STRENGTH IN FLOODED CONDITION

8.8.1 General requirements

8.8.1.1 This Section applies to non-CSR bulk carriers of 150 m and over in length, intending to carry solid bulk cargoes having a density of 1.0 t/m^3 and above, and

(1) single hull, or

(2) double side skin construction in which any part of longitudinal bulkhead is located within $B/5$ or 11.5 m, whichever is less, inboard from the ship's side at right angle to the centreline at the assigned summer load line.

8.8.1.2 Such ships are to have their hull girder strength checked for conditions as specified in Section 2, Chapter 2 and Section 7, Chapter 8 of this PART and in every other condition considered in the intact longitudinal strength calculations, except the following conditions:

(1) harbor conditions;
(2) docking condition afloat;
(3) loading and unloading transitory conditions in port;
(4) loading conditions encountered during ballast water exchange.
8.8.1.3 The hull girder is to be considered intact for checking its overall longitudinal strength.

8.8.2 Flooding criteria
8.8.2.1 The permeability of empty cargo spaces and volume left in loaded cargo spaces above any cargo is to be taken as 0.95.
8.8.2.2 Appropriate permeability and bulk density are to be determined for any cargo carried. "Permeability" for solid bulk cargo means the ratio of the floodable volume between the particles, granules or any larger pieces of cargo, to the gross volume of the bulk cargo. For iron ore, a minimum permeability of 0.3 with a corresponding bulk density of 3.0 t/m³ is to be used. For cement, a minimum permeability of 0.3 with a corresponding bulk density of 1.3 t/m³ is to be used.
8.8.2.3 For packed cargo (such as steel mill products), the actual density of the cargo is to be used with a permeability of zero.

8.8.3 Flooding conditions
8.8.3.1 Each cargo hold is to be considered individually flooded up to the equilibrium waterline. This application is to be applied to self-unloading bulk carriers (SUBC) where the unloading system maintains the watertightness during seagoing operations. In SUBCs with unloading systems that do not maintain watertightness, the longitudinal strength in the flooded conditions is to be considered using the extent to which the flooding may occur.
8.8.3.2 The wave loads in the flooded conditions are assumed to be equal to 80% of those given in Section 2 of Chapter 2.

8.8.4 Stress calculations
8.8.4.1 The overall longitudinal bending stress σ of hull girders at deck and bottom is to be obtained according to 2.2.5.5 of Chapter 2 of this PART, but the wave bending moment is to be determined according to 8.8.3.2 of this Section, with permissible still water bending moment being taken as that in flooding conditions.
8.8.4.2 The shear stress τ of hull girders at any point on the side shell is to be obtained according to 2.2.6.4 of Chapter 2 of this PART, but the wave shear force is to be determined according to 8.8.3.2 of this Section, with permissible still water shear force being taken as that in flooding conditions.

8.8.5 Strength criteria
8.8.5.1 The permissible hull girder bending and shear stresses are to comply with the requirements of Section 2, Chapter 2 of this PART.
8.8.5.2 The buckling strength is to be checked according to 2.2.7 of this PART.

Section 9 STRENGTH OF CORRUGATED TRANSVERSE WATERTIGHT BULKHEADS IN HOLD-FLOODED CONDITIONS

8.9.1 General requirements
8.9.1.1 This Section applies to non-CSR bulk carriers of 150 m and over in length, intending to carry solid bulk cargoes having a density of 1.0 t/m^3, or above, and
(1) single hull, or
(2) double side skin construction in which any part of longitudinal bulkhead is located within $B/5$ or 11.5 m, whichever is less, inboard from the ship's side at right angle to the centreline at the assigned summer load line.
8.9.1.2 The thickness obtained according to the strength criteria given in 8.9.4 of this Section is the net thickness t_{net} required for the strength.
8.9.1.3 The required actual thickness is obtained by adding the corrosion addition given in 8.9.5 of this Section to the net thickness t_{net}.
8.9.1.4 The homogeneous loading condition stated in this Section means a loading condition in which the ratio between the highest and lowest filling ratios, evaluated for any hold, does not exceed 1.20, to be corrected for different cargo densities.

8.9.1.5 The scantlings of corrugated transverse watertight bulkheads determined according to this Section need not be checked again according to 8.4.1 of this Chapter.

8.9.2 Load model

8.9.2.1 General requirements

The loads to be considered as acting on the bulkheads are those given by the combination of the cargo loads with those induced by the flooding of one hold adjacent to the bulkhead under examination. In any case, the pressure due to the flooding water alone is to be considered. This application is to be applied to self-unloading bulk carriers (SUBC) where the unloading system maintains the watertightness during seagoing operations. In SUBCs with unloading systems that do not maintain watertightness, the combination loads acting on the bulkheads in the flooded conditions are to be considered using the extent to which the flooding may occur.

The most severe combinations of cargo induced loads and flooding loads are to be used for the check of strength of each bulkhead, depending on the loading conditions included in the loading manual:

— homogeneous loading conditions;

— non-homogeneous loading conditions;

considering the individual flooding of both loaded and empty holds.

The specified design load limits for the cargo holds are to be represented by loading conditions defined by the Designer in the loading manual.

Non-homogeneous part loading conditions associated with multi-port loading and unloading operations for homogeneous loading conditions need not to be considered according to these requirements.

Holds carrying packed cargoes are to be considered as empty holds for this application.

Unless the ship is intended to carry, in non-homogeneous conditions, only iron ore or cargo having bulk density equal to or greater than 1.78 t/m³, the maximum mass of cargo which may be carried in the hold is to be the mass that fills the hold up to the upper deck level at centreline.

8.9.2.2 The bulkhead flooding head h_f (see Figure 8.9.2.3(1)) is the distance, in m, measured vertically with the ship in the upright position, from the calculation point to a level located at a distance d_f, in m, from the baseline equal to (D being moulded depth):

(1) in general:

— D, for the foremost transverse corrugated bulkhead;

— 0.9 D, for the other corrugated bulkheads.

Where the ship is to carry cargoes having bulk density less than 1.78 t/m³ in non-homogeneous loading conditions, the following values are to be taken:

— 0.95 D, for the foremost transverse corrugated bulkhead;

— 0.85 D, for the other corrugated bulkheads;

(2) for ships less than 50,000 tons deadweight with type B freeboard:

— 0.95 D, for the foremost transverse corrugated bulkhead;

— 0.85 D, for the other corrugated bulkheads.

Where the ship is to carry cargoes having bulk density less than 1.78 t/m³ in non-homogeneous loading conditions, the following values are to be taken:

— 0.9 D, for the foremost transverse corrugated bulkhead;

— 0.8 D, for the other corrugated bulkheads.

8.9.2.3 The pressure P_c exerted by bulk cargo on bulkheads and the force F_c acting on a corrugation in the non-flooded holds are to be obtained from the following formulae:

$$P_c = 9.81 \rho_c h_1 \tan^2 \gamma \quad \text{kN/m}^2$$

$$F_c = 4.91 \rho_c s_1 (d_1 - h_{DB} - h_{LS})^2 \tan^2 \gamma \quad \text{kN}$$

where: ρ_c — bulk cargo density, in t/m³;

h_1 — vertical distance, in m, from the calculation point to horizontal plane corresponding to the level height of the cargo, located at a distance d_1, in m, from the baseline (see Figure 8.9.2.3(1));

γ — 45°− (φ/2), in degrees;

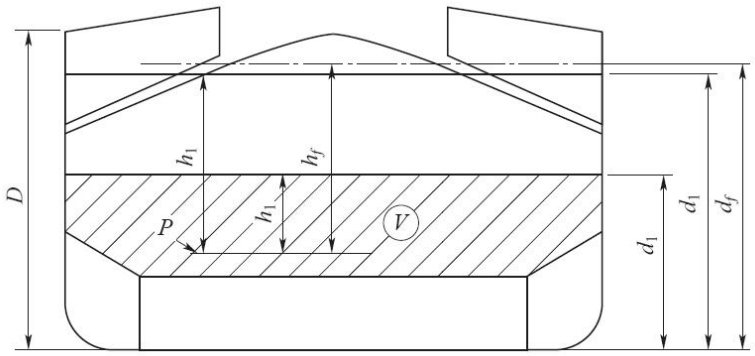
φ — angle of repose of the cargo, in degrees, that may be taken as 35° for iron ore and 25° for cement;

d_1 — see Figure 8.9.2.3 (1), in m;

s_1 — spacing of corrugations, in m (see Figure 8.9.2.3 (2));

h_{LS} — mean height of the lower stool, in m, from the inner bottom;

h_{DB} — height of the double bottom, in m.



V = Volume of cargo *P* = Calculation point

Figure 8.9.2.3(1)

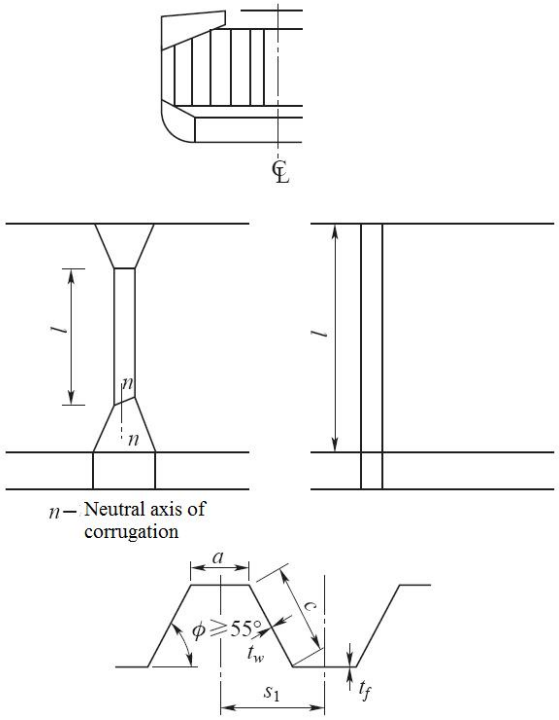


Figure 8.9.2.3(2)

8.9.2.4 Pressure in the flooded holds

(1) The pressure P_{cf} acting on bulkheads and the force F_{cf} acting on a corrugation in the flooded loaded holds are to be obtained from the following formulae:

In the case of $d_f \geq d_1$ (the distance d_f from horizontal plane to the baseline is equal to or greater than the distance d_1 from the level height of the cargo to the baseline in flooded conditions):

$P_{cf} = 10h_f$ kN / m², calculation point between d_f and d_1

$P_{cf} = 10\left\{h_f + \left[\rho_c - (1 - perm)\right]h_1 \tan^2\gamma\right\}$ kN/m², calculation point below d_1

$$F_{cf} = 5s_1\left[\left(d_f - d_1\right)^2 + \left(d_f - d_1 + 0.1P_{le}\right)\left(d_1 - h_{DB} - h_{Ls}\right)\right] \quad \text{kN}$$

In the case of $d_f < d_1$ (the distance from horizontal plane to the baseline is less than the distance from the height of the cargo to the baseline in flooded conditions):

$P_{cf} = 9.81\rho_c h_1 \tan^2\gamma$ kN/m², calculation point between d_f and d_1

$P_{cf} = 10\left\{h_f + \left[\rho_c h_1 - (1 - perm)h_f\right]\tan^2\gamma\right\}$ kN/m², calculation point below d_f

$$F_{cf} = 4.91s_1\left\{\rho_c\left(d_1 - d_f\right)^2\tan^2\gamma + \left[\rho_c\left(d_1 - d_f\right)^2\tan^2\gamma + 0.1P_{le}\right]\left(d_f - h_{DB} - h_{Ls}\right)\right\} \quad \text{kN}$$

where: ρ_c, h_1, γ, s_1, d_1, h_{DB} and h_{Ls} are as given in 8.9.2.3 of this Section;

h_f — flooding head, see 8.9.2.2 of this Section;
perm — permeability of cargo, see 8.8.2.2 of this Chapter;
P_{le} — pressure, in kN/m², at the lower end of the corrugation.

(2) The pressure P_f acting on bulkheads and the force F_f acting on a corrugation in the flooded empty holds are to be obtained as follows:

For the pressure acting on bulkheads, the hydrostatic pressure is to be calculated according to the flooding head h_f.

The force, induced by hydrostatic pressure and acting on a corrugation, is to be obtained from the following formula:

$$F_f = 5 s_1 (d_f - h_{DB} - h_{LS})^2 \quad \text{kN}$$

where: s_1, h_{DB}, h_{Ls} and d_f are as given in 8.9.2.3 of this Section

8.9.2.5 The resultant pressure P acting on any point of bulkheads and the resultant force F acting on a corrugation are to be obtained from the following formulae:

For homogeneous loading conditions: $P = P_{cf} - 0.8\, P_c$ kN / m²

$F = F_{cf} - 0.8\, F_c$ kN

where: P_c, F_c — see 8.9.2.3 of this Section;
P_{cf}, F_{cf} — see 8.9.2.4(1) of this Section.

For non-homogeneous loading conditions: $P = P_{cf}$ kN / m²

$F = F_{cf}$ kN

where: P_c, F_c — see 8.9.2.3 of this Section;
P_{cf}, F_{cf} — whichever is the greatest as given in 8.9.2.4(1) and (2) of this Section.

8.9.3 Bending moment and shear force in bulkhead corrugations

8.9.3.1 The bending moment in bulkhead corrugations is to be obtained from the following formula:

$$M = Fl/8 \quad \text{kN} \cdot \text{m}$$

where: F — see 8.9.2.5 of this Section;
l — span of corrugation, in m, to be taken according to Figure 8.9.2.3(2) and 8.9.3.1. For the definition of l, the internal end of the upper stool is not to be taken more than a distance from the deck at the center line equal to: 3 times the depth of corrugations, in general; 2 times the depth of corrugations, for rectangular stool.

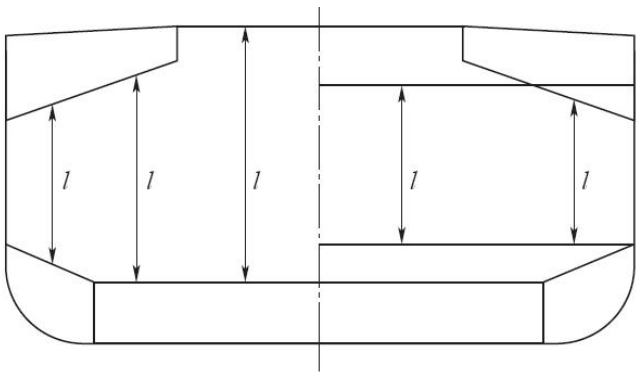

Figure 8.9.3.1

8.9.3.2 The shear force Q at the lower end of bulkhead corrugations is to be obtained from the following formula:

$$Q = 0.8F \quad \text{kN}$$

where: F — see 8.9.2.5 of this Section.

8.9.4 Strength criteria for corrugated bulkheads

8.9.4.1 General requirements

The following criteria are applicable to transverse bulkheads with vertical corrugations (see Figure 8.9.2.3(2)).

For ships of 190 m or over in length, the bulkheads are to be fitted with a lower stool, and generally with an upper stool below deck. For small bulk carriers, both lower and upper stools may not be fitted and corrugations may extend from inner bottom to deck, and if these stools are fitted, they are to comply with the requirements of 8.9.4.1.

The corrugation angle φ shown in Figure 8.9.2.3 (2) is not to be less than 55°.

The net plate thickness of corrugated transverse bulkheads is to comply with 8.9.4.7 of this Section and in addition, corrugated transverse bulkheads are to comply with 8.9.4.2 and 8.9.4.5 of this Section.
The thickness of the lower part of corrugations complying with 8.9.4.2 and 8.9.4.3 is to be maintained for a distance from the inner bottom (if no lower stool is fitted) or the top of the lower stool not less than 0.15*l*.
The thickness of the middle part of corrugations complying with 8.9.4.2 and 8.9.4.4 is to be maintained for a distance from the deck (if no upper stool is fitted) or the bottom of the upper stool not greater than 0.3*l*.
The section modulus of the corrugation in the remaining upper part of the bulkhead is not to be less than 75% of that required for the middle part, corrected for different yield stresses.
Excessive stress concentration is, as far as practicable, to be avoided for transferring the corrugated bulkhead forces and moments to the boundary structures, in particular to the double bottom and cross-deck structures.
In particular, the thickness and stiffening of effective gusset and shedder plates, as defined in 8.9.4.2 of this Section, is to comply with CCS requirements, on the basis of the load model in 8.9.2 of this Section.
Unless otherwise stated, weld connections and materials are to be dimensioned and selected in accordance with the relevant requirements of CCS.
(1) Lower stool
The height of the lower stool is generally not to be less than 3 times the depth of the corrugations. The thickness and material properties of the stool top plate are not to be less than those required for the bulkhead plating above. The thickness and material properties of the upper portion of vertical or sloping stool side plating within the depth equal to the corrugation flange width from the top are not to be less than the required flange plate thickness and material properties to meet the bulkhead stiffness requirement at lower end of corrugation. The structural scantlings of the lower stool are to comply with the relevant requirements of 8.4.1.2 of this Chapter. The section modulus of the stool side vertical stiffeners is not to be less than 85% of that of the corresponding inner bottom longitudinals, and the ends of the stiffeners are to be attached to brackets at the upper and lower ends of the stool.
The distance *d* from the edge of the stool top plate to the surface of the corrugation flange is to be determined in accordance with Figure 8.9.4.1(1). The stool bottom is to be installed in line with double floors and is to have a width not less than 2.5 times the mean depth of the corrugation. The stool is to be fitted with diaphragms in line with the longitudinal double bottom girders for effective support of the corrugated bulkhead. The thickness of the diaphragms is to be the same as that of the longitudinal double bottom girders. Scallops in the brackets and diaphragms in way of the connections to the stool top plate are to be avoided.
Where corrugations are cut at the lower stool, corrugated bulkhead plating is to be connected to the stool top plate by full penetration welds. The stool side plating is to be connected to the stool top plate and the inner bottom plating by either full penetration or deep penetration welds (see Figure 8.9.4.1(2)). The supporting floors are to be connected to the inner bottom by either full penetration or deep penetration welds (see Figure 8.9.4.1(2)).

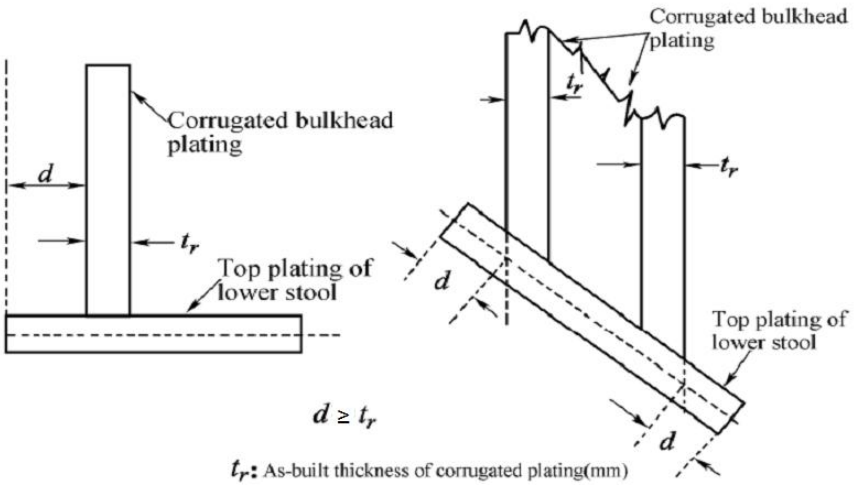

Figure 8.9.4.1(1)

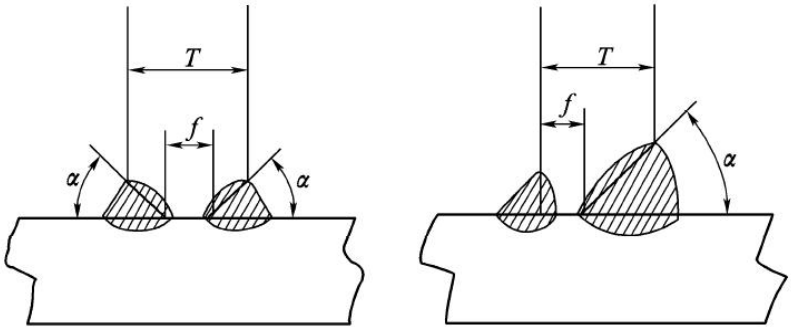

Root face (f) 3 ~ T/3mm
Groove angle (α) 40° ~ 60°

Figure 8.9.4.1(2)

(2) Upper stool

The upper stool, where fitted, is to have a height generally between 2 and 3 times the depth of corrugations. Rectangular stools are to have a height generally equal to twice the depth of corrugations, measured from the depth level and at hatch side girder. The upper stool is to be supported by girders or deep brackets or between the adjacent hatch-end beams.

The width of the stool bottom plate is generally to be the same as that of the lower stool top plate. The top of non-rectangular stools is to have a width not less than twice the depth of corrugations. The thickness and material properties of the stool bottom plate are to be the same as those of the bulkhead plating below. The thickness of stool side plating is not to be less than 80% of that required for the upper part of the bulkhead plating where the same material is used. The structural scantlings of the upper stool are to comply with the relevant requirements of 8.4.1.2 of this Chapter. The section modulus of the stool side vertical stiffeners is not to be less than 85 % of that of the corresponding deck longitudinals. The ends of the stool side vertical stiffeners are to be attached to brackets at upper and lower ends of the stool. Diaphragms are to be fitted inside the stool in line with and effectively attached to longitudinal deck girders extending to the hatch end coaming girders for effective support of the corrugated bulkhead. Scallops in the brackets and diaphragms in way of the connections to the stool bottom plate are to be avoided.

(3) Structural arrangement

At deck, if no stool is fitted, two transverse reinforced beams are to be fitted in line with the corrugation flanges.

At bottom, if no stool is fitted, the corrugated flanges are to be in line with the supporting floors. Corrugated bulkhead plating is to be connected to the inner bottom plating by full penetration welds. The plating of supporting floors is to be connected to the inner bottom by either full penetration or deep penetration welds (see Figure 8.9.4.1(2)). The thickness and material properties of the supporting floors are to be at least equal to those provided for the corrugation flanges. Moreover, the cut-outs for connections of the inner bottom longitudinals to double bottom floors are to be closed by collar plates. The supporting floors are to be connected to each other by shear plates.

Stool side plating is to align with the corrugation flanges and stool side vertical stiffeners and their brackets in lower stool are to align with the inner bottom longitudinals to provide appropriate load transmission between these stiffening members. Stool side plating is not to be knuckled anywhere between the inner bottom plating and the stool top.

8.9.4.2 Bending capacity and shear stress of corrugations

The bending capacity is to comply with the following relationship:

$$\frac{M}{0.5Z_{le}\sigma_{a,le} + Z_m\sigma_{a,m}} \times 10^3 \leq 0.95$$

where: M — bending moment, in kN · m, as given in 8.9.3.1 of this Section;

Z_{le} — section modulus, in cm³, at the lower end of corrugations, calculated according to 8.9.4.3;

Z_m — section modulus, in cm³, at the mid-span of corrugations, calculated according to 8.9.4.4;

$\sigma_{a,le}$ — allowable bending stress, in N/mm², as given in 8.9.4.5, for the lower end of corrugations;

$\sigma_{a,m}$ — allowable bending stress, in N/mm², as given in 8.9.4.5, for the mid-span of corrugations.

In no case Z_m is to be taken greater than the lesser of 1.15 Z_{le} and 1.15 Z'_{le} for calculation of the bending capacity, Z'_{le} being defined below.

In case shedder plates are fitted which:

— are not knuckled;

— are welded to the corrugations and the top of the lower stool by one side penetration welds or equivalent;
— are fitted with a minimum slope of 45° (angle to horizontal plane) and their lower edge is in line with the stool side plating;
— have thickness not less than 75% of that provided by the corrugation flanges;
— and material properties at least equal to those provided by the flanges.

Or gusset plates are fitted which:

— are in combination with shedder plates having thickness, material properties and welded connections in accordance with the above requirements;
— have a height not less than half of the flange width;
— are fitted in line with the stool side plating;
— are generally welded to the top of the lower stool by full penetration welds, and to the corrugations and shedder plates by one side penetration welds or equivalent;
— have thickness and material properties at least equal to those provided by the flanges;

the section modulus Z_{le}, in cm³, is to be taken not larger than the value Z'_{le}, in cm³, given by:

$$Z'_{le} = Z_g + 10^3 \frac{Q \cdot h_g - 0.5 h_g^2 s_1 P_g}{\sigma_a} \quad \text{cm}^3$$

where: Z_g — section modulus, in cm³, of the corrugations calculated according to 8.9.4.4 of this Section, in way of the upper end of shedder or gusset plates, as applicable;
Q — shear force, in kN, as given in 8.9.3.2 of this Section;
h_g — height, in m, of shedder or gusset plates, as applicable, see Figures 8.9.4.2(1) and 8.9.4.2(2);
s_1 — see 8.9.2.3 of this Section;
P_g — resultant pressure, in kN/m², as defined in 8.9.2.5 of this Section, calculated in way of the middle of the shedder or gusset plates, as applicable;
σ_a — allowable bending stress of material, in N/mm², as given in 8.9.4.5.

The shear stress τ is obtained by dividing the shear force Q by the shear area. In general, the shear area may be obtained by multiplying the web sectional area by sin φ, φ being the angle between the web and the flange, in order to account for possible non-perpendicularity between the corrugation webs and flanges.

When calculating the section modulus and the shear area, the net plate thicknesses are to be used.

The section modulus of corrugations is to be calculated on the basis of the following requirements given in 8.9.4.3 and 8.9.4.4.

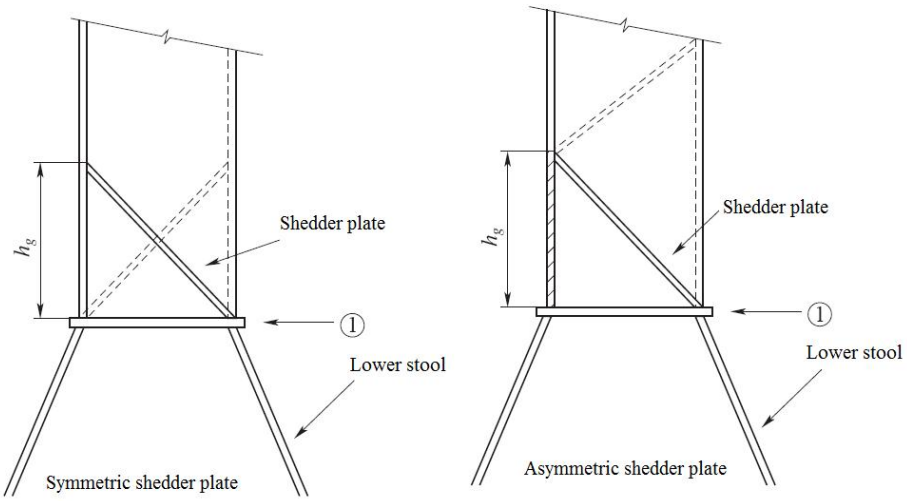

Figure 8.9.4.2(1)

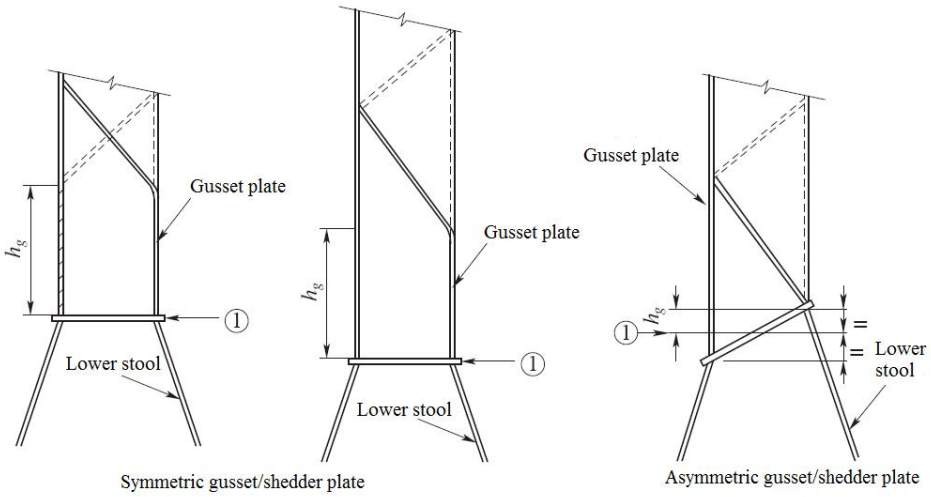

Figure 8.9.4.2(2)

8.9.4.3 Section modulus Z_{le} at the lower end of corrugations

The section modulus is to be calculated with the compression flange having an effective flange width, b_{ef}, not larger than as given in 8.9.4.6(1).

If the corrugation webs are not supported by local brackets below the stool top (or below the inner bottom) in the lower part, the section modulus of the corrugations is to be calculated considering the corrugation webs 30% effective.

(1) Provided that effective shedder plates are fitted (see Figure 8.9.4.2(1)), when calculating the section modulus of corrugations at the lower end (cross-section ① in Figure 8.9.4.2(1)), the area of flange plates, in cm^2, may be increased by:

$$2.5a\sqrt{t_f t_{sh}} \text{ , but not greater than } 2.5at_f \quad \text{cm}^2$$

where: a — width of the corrugation flange, in m, see Figure 8.9.2.3(2);

t_{sh} — net thickness of shedder plate, in mm;

t_f — net thickness of corrugation flange, in mm.

(2) Provided that effective gusset plates are fitted (see Figure 8.9.4.2(2)), when calculating the section modulus of corrugations at the lower end (cross-section ① in Figure 8.9.4.2(2)), the area of flange plates, in cm^2, may be increased by:

$$7h_g t_f \quad \text{cm}^2$$

where: h_g — height of gusset plate, in m (see Figure 8.9.4.2(2)), not to be taken greater than 10 S_{gu}/7;

S_{gu} — width of gusset plate, in m;

t_f — net thickness of corrugation flange, in m, based on the as-built condition.

The lower stool top plate is assumed to be at 0° angle to horizontal plane for (1) and (2) above.

(3) If the lower stool top plate is sloped and at an angle not less than 45° to the horizontal plane, the corrugation webs are to be considered fully effective when calculating the section modulus of corrugations at the lower end. In case effective gusset plates are fitted, when calculating the section modulus of corrugations the area of flange plates may be increased as specified in (2) above. However, no increase may be permitted in the case where shedder plates are fitted without gussets.

If the lower stool top plate is sloped and at an angle less than 45° to the horizontal plane, the effectiveness of corrugation webs is to be obtained by linear interpolation between 30% for 0° and 100% for 45°.

8.9.4.4 Section modulus of corrugations at cross sections other than the lower end

The section modulus is to be calculated with the corrugation webs being considered fully effective and the compression flange having an effective flange width b_{ef} not larger than as given in 8.9.4.6(1).

8.9.4.5 Allowable stress

The normal and shear stresses are not to exceed the allowable values σ_a and τ_a. The allowable stress is given by:

$$\sigma_a = R_{eH}$$
$$\tau_a = 0.5R_{eH}$$

where: R_{eH} — yield stress, in N/mm^2, of the material.

8.9.4.6 Effective compression flange width and shear buckling check

(1) Effective width of the compression flange of corrugations

The effective width b_{ef}, in m, of the corrugation flange is given by:

$$b_{ef} = C_e a$$

where: C_e = $\frac{2.25}{\beta} - \frac{1.25}{\beta^2}$ for $\beta > 1.25$

C_e = 1.0 for $\beta \leq 1.25$

β = $10^3 \frac{a}{t_f}\sqrt{\frac{R_{eH}}{E}}$;

t_f — net flange thickness, in mm;

a — width of the corrugation flange, in m;

R_{eH} — yield stress, in N/mm^2, of the material;

E — modulus of elasticity of the material, in N/mm^2, to be assumed equal to 2.06×10^5 N/mm^2 for steel.

(2) Shear

The buckling check is to be performed for the web plates at the corrugation ends.

The shear stress τ is not to exceed the critical value τ_c, in N/mm^2, obtained by the following:

$$\tau_c = \tau_E \quad \text{for} \quad \tau_E \leqslant \frac{\tau_s}{2}$$

$$\tau_c = \tau_s \left(1 - \frac{\tau_s}{4\tau_E}\right) \quad \text{for} \quad \tau_E > \frac{\tau_s}{2}$$

where: τ_s = $\frac{R_{eH}}{\sqrt{3}}$

R_{eH} — yield stress, in N/mm^2, of the material;

τ_E = $0.9 k_t E \left(\frac{t}{1000c}\right)^2$, N/mm^2;

k_t = 6.34;

E — modulus of elasticity of the material, in N/mm^2;

t — net thickness, in mm, of corrugation web;

c — width, in m, of corrugation web (See Figure 8.9.2.3(2)).

8.9.4.7 Net plate thickness

When the thickness of the flange is the same as that of the web, the bulkhead net plate thickness t is given by:

$$t = 15.27\, s_w \sqrt{\frac{P}{R_{eH}}} \quad \text{mm}$$

where: s_w — plate width, in m, to be taken equal to the width of the corrugation flange or web, whichever is the greater (see Figure 8.9.2.3(2));

P — resultant pressure, in kN/mm^2, as defined in 8.9.2.5, at the bottom of each strake of plating; in all cases, the net thickness of the lowest strake is to be determined using the resultant pressure at the top of the lower stool, or at the inner bottom, if no lower stool is fitted or at the top of shedders, if shedder or gusset/shedder plates are fitted;

R_{eH} — yield stress, in N/mm^2, of the material.

For built-up corrugation bulkheads, when the thickness of the flange is different from that of the web, the net thickness of the narrow plating is not to be less than t_n, in mm, given by:

$$t_n = 15.27\, s_n \sqrt{\frac{P}{R_{eH}}} \quad \text{mm}$$

where: s_n — width of the narrower plating, in m;

R_{eH} — yield stress, in N/mm^2, of the material.

The net thickness of the wider plating, in mm, is not to be taken less than the maximum of the following:

$$t_{w1} = 15.27\, s_w \sqrt{\frac{P}{R_{eH}}} \quad \text{mm}$$

and

$$t_{w2} = \sqrt{462\, S_w^2 \frac{P}{R_{eH}} - t_{np}^2} \quad \text{mm}$$

where: t_{np} — less or equal to actual net thickness of the narrower plating and not to be greater than:

$15.27\, s_w \sqrt{\frac{P}{R_{eH}}}$ mm

R_{eH} — yield stress, in N/mm^2, of the material.

8.9.5 Corrosion addition and steel renewal

8.9.5.1 The corrosion addition is to be taken equal to 3.5 mm.

8.9.5.2 Steel renewal is required where the gauged thickness is less than t_{net} + 0.5 mm. Where the gauged thickness is within the range t_{net} + 0.5 mm and t_{net} + 1.0 mm, coating or annual gauging may be adopted as an alternative to steel renewal.

Section 10 ALLOWABLE HOLD LOADING CONSIDERING HOLD FLOODING

8.10.1 General requirements

8.10.1.1 This Section applies to non-CSR bulk carriers of 150 m and over in length, intending to carry solid bulk cargoes having a density of 1.0 t/m^3, or above, and

(1) single hull, or

(2) double side skin construction in which any part of longitudinal bulkhead is located within B/5 or 11.5 m, whichever is less, inboard from the ship's side at right angle to the centreline at the assigned summer load line.

8.10.1.2 The loading in each hold is not to exceed the allowable hold loading in flooded condition, calculated according to 8.10.4 of this Section, using the shear capacity of the double bottom given in 8.10.3 of this Section.

8.10.1.3 In no case is the allowable hold loading, considering flooding, to be taken greater than the design hold loading in intact condition.

8.10.2 Loading model

8.10.2.1 General requirements

(1) The loads to be considered as acting on the double bottom are those given by the external sea pressure and the combination of the cargo loads with those induced by the flooding of the hold which the double bottom belongs to.

(2) The most severe combinations of cargo induced loads and flooding loads are to be used, depending on the loading conditions included in the loading manual:

— homogeneous loading conditions;

— non-homogeneous loading conditions;

— packed cargo conditions (such as steel products).

(3) For each loading condition, the maximum bulk cargo density to be carried is to be considered in calculation of the allowable hold loading limit.

8.10.2.2 The flooding head h_f (see Figure 8.10.2.2) is the distance, in m, measured vertically with the ship in the upright position, from the inner bottom to a level located at a distance d_f, in m, from the baseline equal to (D being moulded depth):

(1) In general:

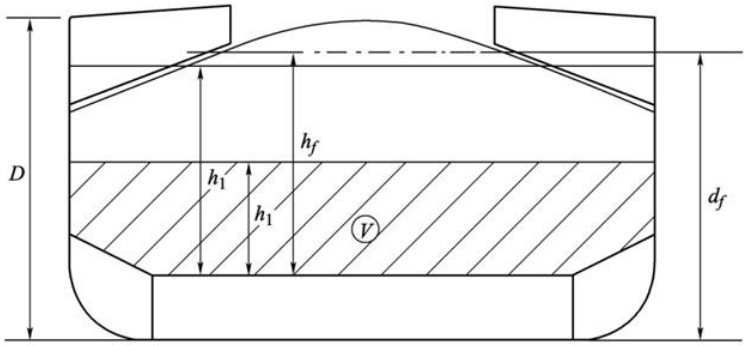
— D, for the foremost hold;

— 0.9D, for the other holds.

(2) For ships less than 50,000 tons deadweight with Type B freeboard:

— 0.95D, for the foremost hold;

— 0.85D, for the other holds.



V = Volume of cargo

Figure 8.10.2.2

8.10.3 Shear capacity of double bottom

8.10.3.1 The shear capacity C of the double bottom is defined as the sum of the shear strength at each end of:

— all floors adjacent to both hopper tanks, less one half of the strength of the two floors adjacent to each stool, or transverse bulkhead if no stool is fitted (see Figures 8.10.3.1(1) and 8.10.3.1(2));

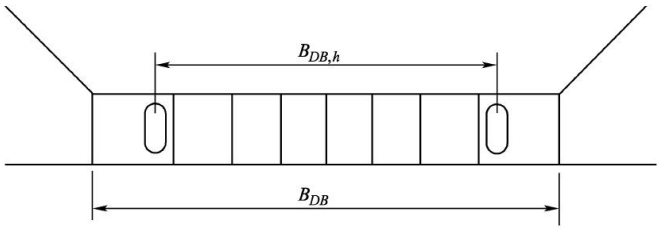


Figure 8.10.3.1(1)

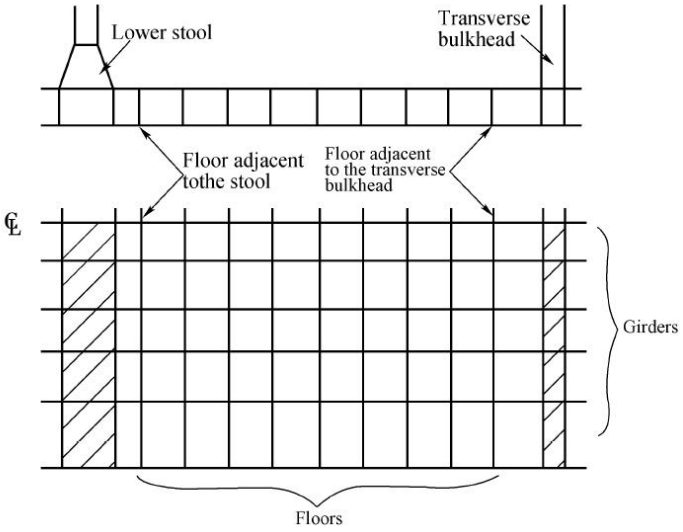

Figure 8.10.3.1(2)

— all double bottom girders adjacent to both stools, or transverse bulkheads if no stool is fitted.

Where in the end holds, girders or floors run out or are not directly attached to the boundary stool, their strength is to be evaluated for the end only.

Note that the floors and girders to be considered are those inside the hold boundaries formed by the hopper tanks and stools (or transverse bulkheads if no stool is fitted). The hopper tank girders and the floors below the lower stools (or transverse bulkheads if no stool is fitted) are not to be included.

Where the geometry and or/the structural arrangement of the double bottom are different from those stated above, special consideration is to be given.

In calculation of the shear strength, the net thickness of floors and girders is to be used. The net thickness t_{net} is given by:

$$t_{net} = t - 2.5 \quad \text{mm}$$

where: t — actual thickness of floors or girders, in mm.

8.10.3.2 The floor shear strength S_{f1} in way of the floor panel adjacent to hoper tanks, in kN, and the floor shear strength S_{f2} in way of the openings in the outmost bay (i.e. that bay which is closer to hopper tank), in kN, are given by the following formulae:

$$S_{f1} = A_f \frac{[\tau]}{\eta_1} \times 10^{-3} \quad \text{kN}$$

$$S_{f2} = A_{fh} \frac{[\tau]}{\eta_2} \times 10^{-3} \quad \text{kN}$$

where: A_f — sectional area, in mm², of the floor panel adjacent to hopper tanks;

A_{fh} — net sectional area, in mm², of the floor panels in way of the openings in the outmost bay (i.e.

that bay which is closer to hopper tank);

$[\tau]$ — allowable shear stress, in N/mm^2, to be taken equal to the lesser of

$$[\tau] = \frac{162R_{eH}^{0.6}}{(s/t_{net})^{0.8}} \quad \text{and} \quad \frac{R_{eH}}{\sqrt{3}}$$

For floors adjacent to the stools or transverse bulkheads, $[\tau]$ may be given by

$$[\tau] = \frac{R_{eH}}{\sqrt{3}}$$

where: R_{eH} — yield stress, in N/mm^2, of the material;

s — spacing of stiffening members, in mm, of panel under consideration;

t_{net} — net thickness, in mm, of floor;

η_1 = 1.10;

η_2 = 1.20.

Where appropriate reinforcements are fitted around openings, η_2 may be reduced down to 1.10.

8.10.3.3 The girder shear strength S_{g1} in way of the girder panel adjacent to stools (or transverse bulkheads, if not stool is fitted), in kN, and the girder shear strength S_{g2} in way of the largest opening in the outmost bay (i.e. that bay which is closer to hopper tank), in kN, are given by:

$$S_{g1} = A_g \frac{[\tau]}{\eta_1} \times 10^{-3} \quad \text{kN}$$

$$S_{g2} = A_{gh} \frac{[\tau]}{\eta_2} \times 10^{-3} \quad \text{kN}$$

where: A_g — sectional area, in mm², of the girder panel adjacent to stools (or transverse bulkheads, if no stool is fitted);

A_{gh} — net sectional area, in mm², of the girder panel in way of the largest opening in the outmost bay (i.e. that bay which is closer to stool, or transverse bulkhead, if no stool is fitted);

$[\tau]$ — the same as in 8.10.3.2 of this Section, t_{net} being net thickness of girder in mm;

η_1 = 1.10;

η_2 = 1.15, may be reduced down to 1.10 where appropriate reinforcements are fitted around openings.

8.10.4 Allowable hold loading

8.10.4.1 The allowable hold loading is given by:

$$W = \frac{\rho_c V}{F} \quad t$$

where: F — coefficient, 1.1 in general and 1.05 for steel products;

ρ_c — cargo density, in t/m³, for steel products, ρ_c is to be taken as the density of steel;

V — volume, in m³, occupied by cargo at a level h_1, to be obtained by the following formula:

$$h_1 = \frac{X}{9.81\rho_c}$$

X = for bulk cargoes, the lesser of X_1 and X_2 given by:

$$X_1 = \frac{Z + 10(E - h_f)}{1 + \frac{1}{\rho_c}(perm - 1)}$$

$$X_2 = Z + 10\,(E - h_f\, perm)$$

for steel products, X may be taken as X_1, using $perm = 0$;

E — ship immersion, in m, for flooded hold condition, to be obtained by:

$$d_f - 0.1D$$

d_f,D — determined according to Figure 8.10.2.2;

h_f — flooding head, in m;

$perm$— cargo permeability; it need not be taken as greater than 0.3;

Z — the lesser of Z_1 and Z_2 given by:

$$Z_1 = \frac{C_h}{A_{DBh}}$$

$$Z_2 = \frac{C_e}{A_{DBe}}$$

C_h — shear capacity of the double bottom, in kN, considering, for each floor, the lesser of the shear

strength S_{f1} and S_{f2} and, for each girder, the lesser of the shear strength S_{g1} and S_{g2};

C_e — shear capacity of the double bottom, in kN, considering, for each floor, the shear strength S_{f1} and, for each girder, the lesser of the shear strengths S_{g1} and S_{g2};

$$A_{DBh} = \sum_{i+1}^{n} S_i B_{DBi} ;$$

$$A_{DBe} = \sum_{i+1}^{n} S_i (B_{DB} - s_l) ;$$

n — number of floors between stools (for transverse bulkheads, if no stool is fitted);

S_i — space of ith-floor, in m;

$B_{DBi} = B_{DB} - s_l$, for floors whose shear strength is given by S_{f1};

$B_{DBi} = B_{DBh}$, for floors whose shear strength is given by S_{f2};

B_{DB} — breadth of double bottom, in m, between hopper tanks (see Figure 8.10.3.1(1));

B_{DBh} — distance, in m, between the two considered openings (see Figure 8.10.3.1(1));

s_l — spacing, in m, of double bottom longitudinals adjacent to hopper tanks.

Section 11 HATCH COVERS OF CARGO HOLDS

8.11.1 General requirements

8.11.1.1 This Section applies to bulk carriers, ore carriers and combination carriers. The hatch covers of cargo holds are to comply with the relevant requirements of Section 20, Chapter 2 of this PART.

Section 12 HARMONIZED NOTATIONS AND CORRESPONDING DESIGN LOADING CONDITIONS FOR BULK CARRIERS

8.12.1 General requirements

8.12.1.1 This Section is not intended to prevent any other loading conditions to be included in the loading manual for which calculations are to be submitted as required, nor is it intended to replace in any way the required loading manual/instrument.

8.12.1.2 A bulk carrier may in actual operation be loaded differently from the design loading conditions specified in the loading manual, provided limitations for longitudinal and local strength as defined in the loading manual and loading instrument onboard and applicable stability requirements are not exceeded.

8.12.2 Application

8.12.2.1 Typical bulk carriers of 150 m or over in length and constructed with single deck, double bottom, topside tanks and hopper tanks in the cargo hold region and of single side skin or double side skin construction are to comply with relevant requirements of this Section. General dry cargo ships intended to carry cargoes in bulk may also be assigned relevant notations provided that relevant requirements of this Section are satisfied.

8.12.2.2 The loading conditions listed in 8.12.4 are to be used for the checking of rules criteria regarding longitudinal strength, local strength, capacity and disposition of ballast tanks and stability. The longitudinal strength is to comply with the requirements of Section 2, Chapter 2 and Section 8, Chapter 8 of this PART. The loading conditions listed in 8.12.5 are to be used for the checking of local strength. Direct calculations are to be carried out for the strength of primary structural members within the cargo area in accordance with the requirements of 8.1.4 of this Chapter.

8.12.2.3 Maximum draught mentioned in this Section is to be taken as moulded summer load line draught.

8.12.2.4 Filling rate mentioned in this Section is the rate of cargo mass to hold cubic capacity. The hold cubic capacity is to be taken up to the top of the hatch coaming in calculation.

8.12.3 Harmonized notations and annotations

8.12.3.1 Bulk carriers complying with this Section are to be assigned one of the following notations:

(1) BC–A: for bulk carriers:

— designed to carry dry bulk cargoes of cargo density 1.0 t/m^3 and above,

— with specified holds empty at maximum draught, and

— in addition to BC–B conditions.

(2) BC–B: for bulk carriers:

— designed to carry dry bulk cargoes of cargo density of 1.0 t/m^3 and above,
— with all cargo holds loaded, and
— in addition to BC–C conditions.

(3) BC–C: for bulk carriers:
— designed to carry dry bulk cargoes of cargo density less than 1.0 t/m^3.

8.12.3.2 Additional notations:

(1) {Maximum cargo density x.y t/m^3}: When the maximum design cargo density is less than 3.0 t/m^3, for bulk carriers, the limitation is to be given after the harmonized notation, indicating the maximum cargo density allowed to be loaded. This additional notation is only applicable to notations BC–A and BC–B. For general dry cargo ships intended to carry cargoes in bulk, when the maximum density of the bulk cargo designed under the bulk cargo loading condition is less than 3.0 t/m^3, this notation is assigned to indicate the limitation and the maximum density value of the bulk cargo allowed to be loaded.

(2) {No MP}: When requirements for loading and unloading in multiple ports have not been raised in accordance with 8.12.5.3 in the design of bulk carrier, the limitation is to be given after the harmonized notation. This additional notation is applicable to all harmonized notations (BC-A, BC-B, BC-C). For general dry cargo ships intended to carry cargoes in bulk, this notation is assigned to show the limitation when the bulk cargo loading condition has not been designed for loading and unloading in multiple ports in accordance with the Rules.

(3) {Holds a, b, …may be empty}: When specified empty holds are allowed in the design of bulk carriers, this additional notation is to be given after the harmonized notation. This notation is only applicable to notation BC-A. For general dry cargo ships intended to carry cargoes in bulk, this notation is assigned to specify the empty hold No. when specified empty holds are allowed in the design of bulk cargo loading condition.

8.12.4 Design loading conditions (General)

8.12.4.1 Harmonized notation BC–C is to cover:

Homogeneous cargo loaded condition where the cargo density corresponds to all cargo holds, including hatchways, being 100% full at maximum draught with all ballast tanks empty.

8.12.4.2 Harmonized notation BC–B is to cover:

The condition as required by 8.12.4.1, plus: homogeneous cargo loaded condition with cargo density 3.0 t/m^3, and the same filling rate in all cargo holds at maximum draught with all ballast tanks empty.

In cases where the cargo density applied for this design loading condition is less than 3.0 t/m^3, the maximum density of the cargo that the vessel is allowed to carry is to be indicated with the additional notation (Maximum cargo density x.y t/m^3) as specified in 8.12.3.2(1).

8.12.4.3 Harmonized notation BC–A is to cover:

The condition as required by 8.12.4.1 and 8.12.4.2, plus: at least one cargo loaded condition with specified holds empty, with cargo density 3.0 t/m^3, and the same filling rate in all loaded cargo holds at maximum draught with all ballast tanks empty.

The combination of specified empty holds is to be indicated with the annotation (Holds a, b, ... may be empty). In such cases where the design cargo density applied is less than 3.0 t/m^3, the maximum density of the cargo that the vessel is allowed to carry is to be indicated within the annotation, e.g. (Maximum cargo density x.y t/m^3, Holds a, b, ... may be empty).

8.12.4.4 Ballast conditions (applicable to all notations)

(1) Ballast tank capacity and disposition

All bulk carriers are to have ballast tanks of sufficient capacity and so disposed to at least fulfill the following requirements:

① Normal ballast condition for the purpose of this Section is a ballast (no cargo) condition where:
— all cargo holds or holds adapted for the carriage of water ballast at sea are to be empty;
— the ballast tanks may be full, partially full or empty. Where partially full option is exercised, the conditions in 2.2.2.5 of Section 2, Chapter 2 of this PART are to be complied with;
— the propeller is to be fully immersed; and
— the trim is to be by the stern and is not to exceed 0.015L, where L is the length between perpendiculars of the ship. In the assessment of the propeller immersion and trim, the draughts at the forward and after perpendiculars may be used.

② Heavy ballast condition for the purpose of this Section is a ballast (no cargo) condition where:
— at least one cargo hold adapted for carriage of water ballast at sea, where required or provided, is to be full;
— the ballast tanks may be full, partially full or empty. Where partially full option is exercised, the conditions in 2.2.2.5 of Section 2, Chapter 2 of this PART are to be complied with;

— the propeller immersion I/D is to be at least 0.60 where I = the distance from propeller centerline to the waterline, in m, D = propeller diameter, in m;
— the trim is to be by the stern and is not to exceed 0.015L, where L is the length, in m, between perpendiculars of the ship; and
— the moulded forward draught in the heavy ballast condition is not to be less than the smaller of 0.03L or 8 m.

(2) Strength requirements

① Normal ballast condition:

— the structures of bottom forward are to be strengthened in accordance with the relevant requirements of 2.15.3 of Section 15, Chapter 2 of this PART against slamming for the condition of 8.12.4.4(1)① where the lightest forward draught is less than 0.04L;
— the longitudinal strength requirements are to be met for the condition of 8.12.4.4(1)①; and
— in addition, the longitudinal strength requirements are to be met with all ballast tanks 100% full for the condition of 8.12.4.4(1)① where the ballast tanks may be partially full or empty.

② Heavy ballast condition:

— the longitudinal strength requirements are to be met for the condition of 8.12.4.4(1)②;
— in addition, the longitudinal strength requirements are to be met with all ballast tanks 100% full for the condition of 8.12.4.4(1)② where the ballast tanks may be partially full or empty; and
— where more than one hold is adapted and designated for the carriage of water ballast at sea, it will not be required that two or more holds be assumed 100% full simultaneously in the longitudinal strength assessment, unless such conditions are expected in the heavy ballast condition. Unless each hold is individually investigated, the designated heavy ballast hold and any/all restrictions for the use of other ballast hold(s) are to be indicated in the loading manual.

8.12.4.5 Unless otherwise specified, each of the design loading conditions defined in 8.12.4 is to be investigated for the arrival and departure conditions as defined below.

(1) Departure condition: with bunker tanks not less than 95% full and other consumables 100%;

(2) Arrival condition: with 10% of consumables.

8.12.5 Design loading conditions (for local strength)

8.12.5.1 The maximum allowable or minimum required cargo mass in a cargo hold, or in two adjacently loaded holds, is related to the net load on the double bottom. The net load on the double bottom is a function of draft, cargo mass in the cargo hold, as well as the mass of fuel oil and ballast water contained in double bottom tanks. For the purpose of the conditions in 8.12.5.2 to 8.12.5.6, the following definitions apply:

(1) M_H: the actual cargo mass in a cargo hold corresponding to a homogeneously loaded condition at maximum draught;

(2) M_{Full}: the cargo mass in a cargo hold corresponding to cargo with virtual density (homogeneous mass/hold cubic capacity, minimum 1.0 t/m^3) filled to the top of the hatch coaming. M_{Full} is in no case to be less than M_H;

(3) M_{HD}: the maximum cargo mass allowed to be carried in a cargo hold according to design loading condition(s) with specified holds empty at maximum draft.

8.12.5.2 For all ships within the scope of application, the cargo hold is to be checked in accordance with the following loading conditions.

(1) Any cargo hold is to be capable of carrying M_{Full} with fuel oil tanks in double bottom in way of the cargo hold, if any, being 100% full and ballast water tanks in the double bottom in way of the cargo hold being empty, at maximum draught (see Figure 8.12.5.2(1)).

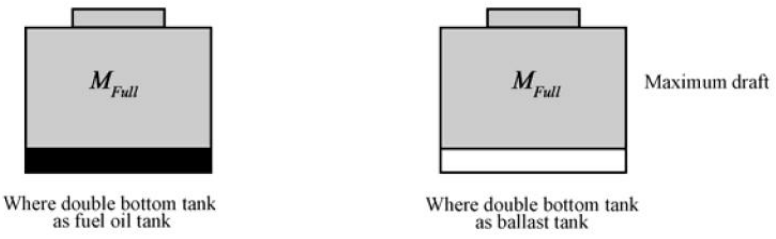

Figure 8.12.5.2(1)

(2) Any cargo hold is to be capable of carrying minimum 50% of M_H, with all double bottom tanks in way

of the cargo hold being empty, at maximum draught (see Figure 8.12.5.2(2)).

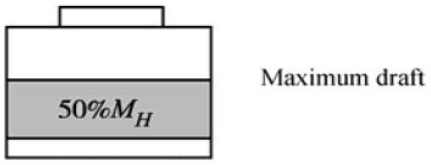

Figure 8.12.5.2(2)

(3) Any cargo hold is to be capable of being empty, with all double bottom tanks in way of the cargo hold being empty, at the deepest ballast draught (see Figure 8.12.5.2(3)).

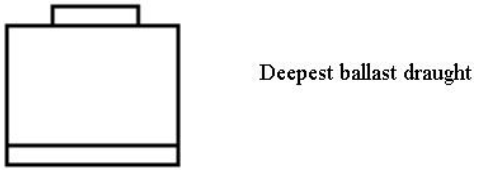

Figure 8.12.5.2(3)

8.12.5.3 For all ships within the scope of application, the cargo hold is to be checked in accordance with the following loading conditions, except when notation (No MP) is assigned

(1) Any cargo hold is to be capable of carrying M_{Full} with fuel oil tanks in double bottom in way of the cargo hold, if any, being 100% full and ballast water tanks in the double bottom in way of the cargo hold being empty, at 67% of maximum draught (see Figure 8.12.5.3(1)).

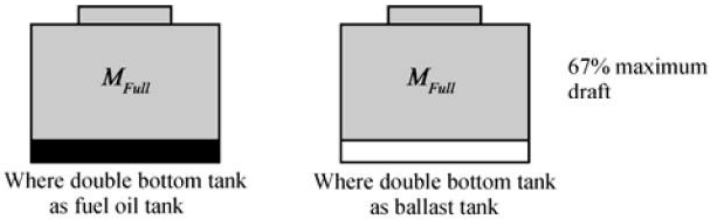

Figure 8.12.5.3(1)

(2) Any cargo hold is to be capable of being empty with all double bottom tanks in way of the cargo hold being empty, at 83% of maximum draught (see Figure 8.12.5.3(2)).

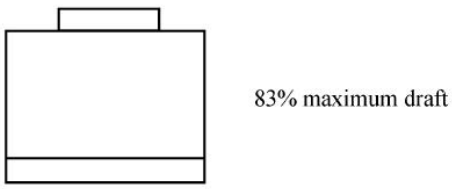

Figure 8.12.5.3(2)

(3) Any two adjacent cargo holds are to be capable of carrying M_{Full} with fuel oil tanks in double bottom in way of the cargo hold, if any, being 100% full and ballast water tanks in the double bottom in way of the cargo hold being empty, at 67% of the maximum draught. This requirement to the mass of cargo and fuel oil in double bottom tanks in way of the cargo hold applies also to the condition where the adjacent hold is filled with ballast, if applicable (see Figure 8.12.5.3(3)).

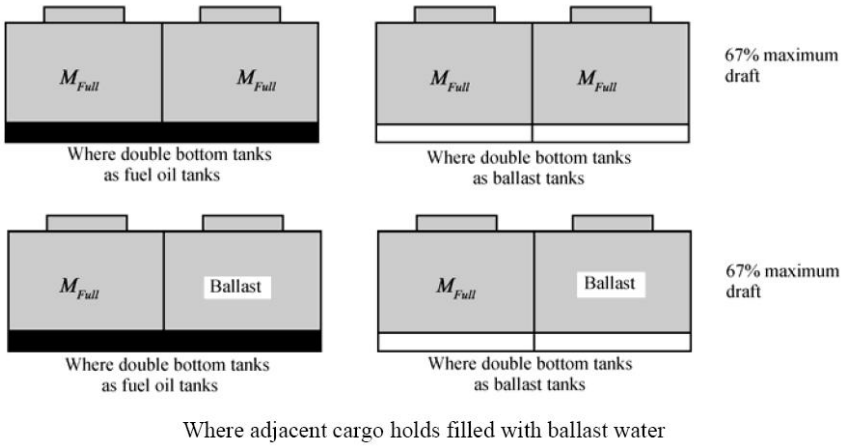

Figure 8.12.5.3(3)

(4) Any two adjacent cargo holds are to be capable of being empty, with all double bottom tanks in way of the cargo hold being empty, at 75% of maximum draught (see Figure 8.12.5.3 (4)).

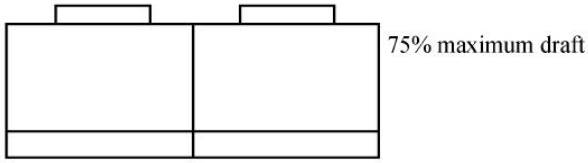

Figure 8.12.5.3(4)

8.12.5.4 Additional requirements for ships where empty holds are allowed in the bulk cargo loading condition

(1) Cargo holds, which are intended to be empty at maximum draught, are to be capable of being empty with all double bottom tanks in way of the cargo hold also being empty (see Figure 8.12.5.4 (1)).

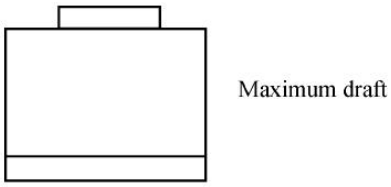

Figure 8.12.5.4(1)

(2) Cargo holds, which are intended to be loaded with high density cargo, are to be capable of carrying M_{HD} plus 10% of M_H, with fuel oil tanks in the double bottom in way of the cargo hold, if any, being 100% full and ballast water tanks in the double bottom being empty in way of the cargo hold, at maximum draught. In operation the maximum allowable cargo mass is to be limited to M_{HD} (see Figure 8.12.5.4 (2)).

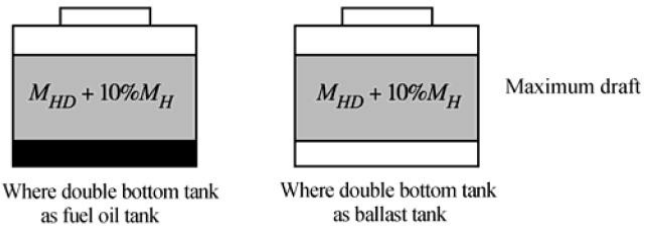

Figure 8.12.5.4(2)

(3) Any two adjacent cargo holds which according to a design loading condition may be loaded with the next holds being empty, are to be capable of carrying 10% of M_H in each hold in addition to the maximum cargo load M'_{HD} according to that design loading condition, with fuel oil tanks in the double bottom in way of the cargo hold, if any, being 100% full and ballast water tanks in the double bottom in way of the cargo hold being empty, at maximum draught. In operation the maximum allowable mass is to be limited to the

maximum cargo load according to the design loading conditions (see Figure 8.12.5.4 (3)).

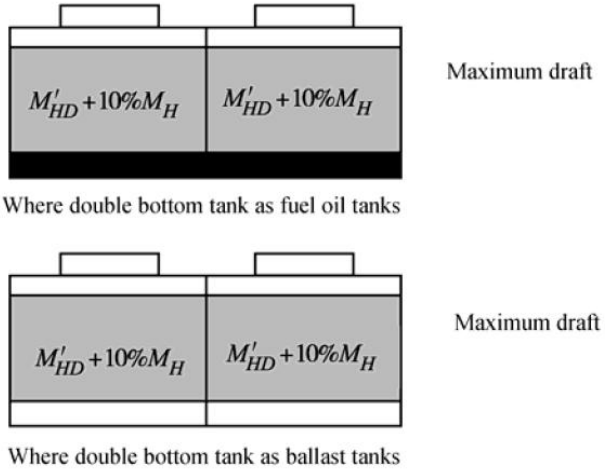

Figure 8.12.5.4(3)

8.12.5.5 Additional conditions applicable for ballast hold(s) only

(1) Cargo holds, which are designed as ballast water holds, are to be capable of being 100% full of ballast water including hatchways, with all double bottom tanks in way of the cargo hold being 100% full, at any heavy ballast draught. For ballast holds adjacent to topside wing, hopper and double bottom tanks, it is to be strengthwise acceptable that the ballast holds are filled when the topside wing, hopper and double bottom tanks are empty (see Figure 8.12.5.5 (1)).

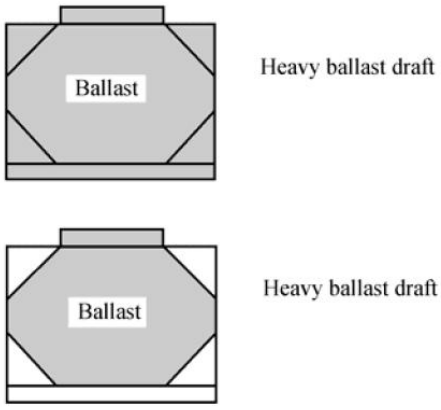

Figure 8.12.5.5(1)

8.12.5.6 Additional conditions applicable during loading and unloading in harbor only

(1) Any single cargo hold is to be capable of holding the maximum allowable seagoing mass at 67% of maximum draught, in harbor condition (see Figure 8.12.5.6 (1)).

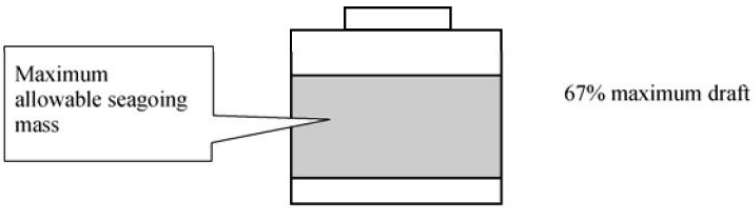

Figure 8.12.5.6(1)

(2) Any two adjacent cargo holds are to be capable of carrying M_{Full} ,with fuel oil tanks in the double bottom in way of the cargo hold, if any, being 100% full and ballast water tanks in the double bottom in way of the cargo hold being empty, at 67% of maximum draught, in harbor condition (see Figure 8.12.5.6(2)).

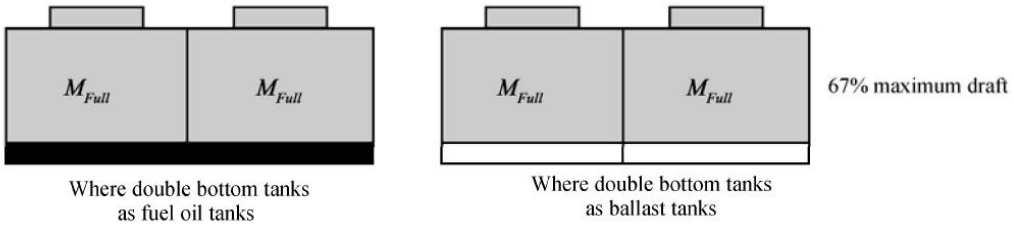

Figure 8.12.5.6(2)

(3) At reduced draught during loading and unloading in harbor, the maximum allowable mass in a cargo hold may be increased by 15% of the maximum mass allowed at the maximum draught in sea-going condition, but is not to exceed the mass allowed at maximum draught in the sea-going condition. The minimum required mass may be reduced by the same amount.

8.12.5.7 Hold mass curves

(1) Based on the design loading criteria for local strength, as given in 8.12.5.2 to 8.12.5.6 above, hold mass curves are to be included in the loading manual and the loading instrument, showing maximum allowable and minimum required mass as a function of draught, in sea-going condition as well as during loading and unloading in harbor (see Section 7, Chapter 8 of this PART).

(2) At other draughts than those specified in the design loading conditions above, the maximum allowable and minimum required mass is to be adjusted for the change in buoyancy acting on the bottom. Change in buoyancy is to be calculated using water plane area at each draught.

Section 13 REQUIREMENTS FOR THE FITTING OF A FORECASTLE

8.13.1 General requirements

8.13.1.1 This Section applies to bulk carriers, ore carriers and combination carriers.

8.13.1.2 Ships to which this Section applies are to be fitted with an enclosed forecastle on the freeboard deck.

8.13.1.3 In addition, structural arrangement and scantlings of the forecastle are to comply with the applicable requirements of Section 17, Chapter 2 of this PART.

8.13.2 Arrangement

8.13.2.1 The forecastle is to be located on the freeboard deck with its aft bulkhead fitted in way or aft of the forward bulkhead of the foremost hold, as shown in Figure 8.13.2.1. However, if this requirement hinders hatch cover operation, the aft bulkhead of the forecastle may be fitted forward of the forward bulkhead of the foremost cargo hold provided the forecastle length is not less than 0.07 L_L of ship's length abaft the forward perpendicular, where the ship's length and forward perpendicular are defined in Regulation 3 of Annex I of the International Convention on Load Lines, 1966 and its 1988 amendments.

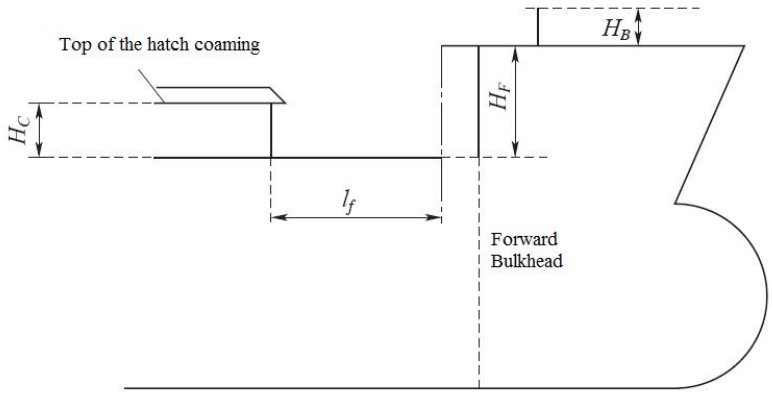

Figure 8.13.2.1

8.13.2.2 The forecastle height H_F above the main deck is not to be less than:

$$H_{F1} = H_{sh} \quad \text{m}$$

$$H_{F2} = H_C + 0.5 \quad \text{m}$$

where: H_{sh} — the standard height of a superstructure as specified in the International Convention on Load Lines, 1966 and its 1988 amendments;

H_C — the height, in m, of the forward transverse hatch coaming of cargo hold No.1,

whichever is the greater.

8.13.2.3 All points of the aft edge of the forecastle deck are to be located at a distance l_f:

$$l_f \le 5\sqrt{H_F - H_C} \quad \text{m}$$

from the hatch coaming plate in order to apply the reduced loading to the No.1 forward transverse hatch coaming and No.1 hatch cover in applying 2.20.2.2(2)② and 2.20.2.9(2)③, respectively, of Chapter 2 of this PART.

8.13.2.4 A breakwater is not to be fitted on the forecastle deck with the purpose of protecting the hatch coaming or hatch covers. If fitted for other purposes, it is to be located such that its upper edge at centre line is not less than H_B/tan 20° forward of the aft edge of the forecastle deck, where H_B is the height of the breakwater above the forecastle (see Figure 8.13.2.1).

Section 14 DOUBLE SIDE STRUCTURE

8.14.1 General requirements

8.14.1.1 This Section applies to the double side skin construction within the cargo area of bulk carriers.

8.14.1.2 Manholes are to be provided in transverse webs and horizontal girders. The manholes may either be round or elliptical. The long axis of an elliptical manhole is to be vertical to or along the length of the ship. Except access openings, the holes in upper and lower adjacent horizontal girders are not to be on the same vertical line. The manhole edges are to be strengthened.

8.14.2 Structural arrangements of double side skin

8.14.2.1 Where double side skin is provided in the cargo area, the inner shell is to extend as far forward and aft as practicable at the fore and aft ends of the cargo hold and is to be effectively connected and tapered to the structures there. Supporting members within the inner shell are to be provided in double side skin instead of one side of the cargo hold.

8.14.2.2 Cargo loading is not permitted inside double side skin, and the inner shell is to be so arranged that all cargo holds are inboard of double side skin.

8.14.2.3 Where the load line length L_L is 150 m and upwards, the width of double side skin at any transverse section of the hull is not to be less than 1 m. Such width is the distance between the outer shell and the inner shell, measured perpendicular to the side shell.

8.14.2.4 Where the load line length L_L is 150 m and upwards, the structural arrangement of double side skin is to comply with the following:

(1) the minimum width of the clear passage through the double-side skin space in way of obstructions such as piping or vertical ladders is not to be less than 0.6 m;

(2) where the inner and outer skins are transversely framed, the minimum clearance between the inner surfaces of the frames is not to be less than 0.6 m;

(3) where the inner and outer skins are longitudinally framed, the minimum clearance between the inner surfaces of the frames is not to be less than 0.8 m. Outside the parallel part of the cargo hold length, this clearance may be reduced where necessitated by the structural configuration, but not less than 0.6 m.

Consideration over end brackets of frames is not necessary when measuring the clearance, see Figure 8.14.2.4 for the measurement.

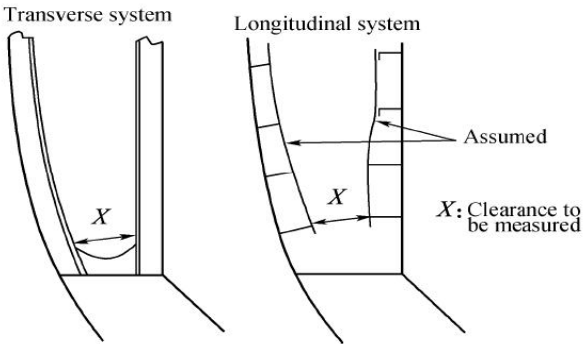

Figure 8.14.2.4

8.14.2.5 Transverse webs are to be provided within double side skin in line with the transverse watertight bulkheads of cargo holds. Otherwise, transverse framing is to be provided and ballast tanks are to be provided with swash bulkheads.

8.14.2.6 Transverse framing or transverse webs, which are to be provided or alternately provided within double side skin in line with double bottom transverses, together with transverse supporting members in topside tanks and hopper tanks and double bottom transverses, form transverse strength framing.

8.14.2.7 Horizontal girders must be provided at bottom of topside tanks and at top of hopper tanks. Manholes may not be provided for the sake of subdivision and stability.

8.14.3 Minimum thickness

8.14.3.1 The minimum thickness t of webs and face plates of primary members, horizontal girders, transverse webs and inner shell plating in double side skin is not to be less than that obtained from the following formula:

$$t = 7.5 + 0.015L, \text{ but need not be greater than 11 mm}$$

8.14.3.2 Where specified empty spaces are within double side skin, the minimum thickness as required in 8.14.3.1 may be reduced by 1 mm.

8.14.4 Inner shell plating

8.14.4.1 Where specified empty spaces are within double side skin, in addition to complying with the requirement in 8.14.3 of this Section, the thickness t of inner shell plating is not to be less than that obtained from the following formula:

$$t = 4s\sqrt{hK} \quad \text{mm}$$

where: s — spacing of stiffeners, in m;

h — vertical distance, in m, measured from the lower edge of the inner shell plating strake to bulkhead deck;

K — material factor.

Where no hopper tank is provided, the thickness obtained of strake at the bottom of the inner shell plating is to be increased by 1 mm, the width is not to be less than 900 mm. Where the thickness of inner shell plating is much less than that of the girder web to which the shell plating is connected, the thickness of the inner shell plating in way of the connecting area is in general to be increased.

8.14.4.2 Where ballast tanks are within double side skin, in addition to complying with the requirement in 8.14.3 of this Section, the thickness t of inner shell plating is not to be less than that obtained from the following formula:

$$t = 4s\sqrt{hK} + 2.5 \quad \text{mm}$$

where: s — spacing of stiffeners, in m;

h — vertical distance, in m, measured from the lower edge of the inner shell plating strake to the top of the ballast tank, or half the distance to the top of the overflow, whichever is the greater;

K — material factor.

Where no hopper tank is provided, the thickness obtained of the lowest strake of inner shell plating is to be increased by 1 mm.

8.14.4.3 Where no topside tank is provided, the thickness of inner shell plating within $0.1D$ of strength deck is not to be less than that obtained from the following formula:

$$t = 4s\sqrt{DK} \quad \text{mm}$$

where: s — spacing of stiffeners, in m;

D — molded depth, in m;

K — material factor.

However, the thickness of inner shell plating is not to be necessarily greater than that of sheer strakes with same frame spacing.

8.14.4.4 Stiffener spacing of inner shell plating is to be the same as that of side frames or side longitudinals.

8.14.4.5 In specified empty spaces, the section modulus W of inner shell plating stiffeners is not to be less than that obtained from the following formula:

$$W = 3shl^2K \quad \text{cm}^3$$

where: s — spacing of stiffeners, in m;

h — vertical distance, in m, measured from the mid-span of the stiffener to upper deck,

but not less than 2 m;

l — span of stiffener, in m;

K — material factor.

8.14.4.6 In the ballast tank, the section modulus W and the moment of inertia I of inner shell stiffeners are not to be less than those obtained from the following formulae respectively:

$$W = 8.2shl^2K \quad \text{cm}^3$$

$$I = 2.3Wl/K \quad \text{cm}^4$$

where: s — spacing of stiffeners, in m;

h — vertical distance, in m, measured from the mid-span of the stiffener to tank top, or half the distance to the top of the overflow, whichever is the greater;

l — span of stiffener, in m;

K — material factor.

8.14.4.7 In ships over 150 m in length or where higher tensile steel is used for horizontal stiffeners, horizontal stiffeners of inner shell plating within $0.1D$ from bottom and strength deck are to pass continuously through watertight transverse webs. Where horizontal stiffeners are cut at watertight transverse webs, they are to be bracketed to transverse webs.

8.14.4.8 Tripping brackets are to be provided at both ends of vertical stiffeners.

8.14.4.9 Scantlings of tripping brackets are to comply with the requirements in 1.2.6 of Chapter 1 of this PART.

8.14.5 Transverse webs

8.14.5.1 Where watertight transverse webs in double side skin constitute boundaries of specified empty spaces, their scantlings are to comply with the requirements in 8.14.4.1 and 8.14.4.5 of this Section.

8.14.5.2 Where watertight transverse webs in double side skin constitute boundaries of ballast tanks, their scantlings are to comply with the requirements in 8.14.4.2 and 8.14.4.6 of this Section.

8.14.5.3 Stiffeners are to be provided in between side longitudinals and inner shell horizontal stiffeners in way of transverse webs.

8.14.5.4 Where longitudinal framing is provided inside double side skin, non-watertight transverse webs supporting side longitudinals and inner shell horizontal stiffeners are to be provided or alternately provided at the same frame of bottom transverse in double side skin. The thickness of non-watertight transverse webs is to comply with the requirements in 8.14.3 of this Section. The side longitudinals and inner shell horizontal stiffeners are to pass through the non-watertight transverse webs.

8.14.6 Platform in deep tanks

8.14.6.1 The platform in deep tanks is to comply with the relevant requirements of Section 13, Chapter 2 of this PART.

Section 15 ADDITIONAL REQUIREMENTS FOR STIFFENING STRUCTURAL MEMBERS

8.15.1 General requirements

8.15.1.1 This Section applies to bulk carriers of 150 m in load line length and upwards, carrying solid bulk cargoes having a density of 1 t/m^3 and above, as defined in SOLAS Regulation XII/1.

8.15.2 Materials

8.15.2.1 For ships with single side structures, the steel grade is not to be less than grade D or DH for:

(1) the lower bracket of side frames;

(2) side shell plate between two points located to $0.125l$ above and $0.125l$ below the intersection of side shell and bilge hopper sloping plate or inner bottom plate, l being the span of the side frame.

(3) In case of side frames built with multiple spans, the above requirements are to apply to the lower part only, see Figure 8.15.2.1.

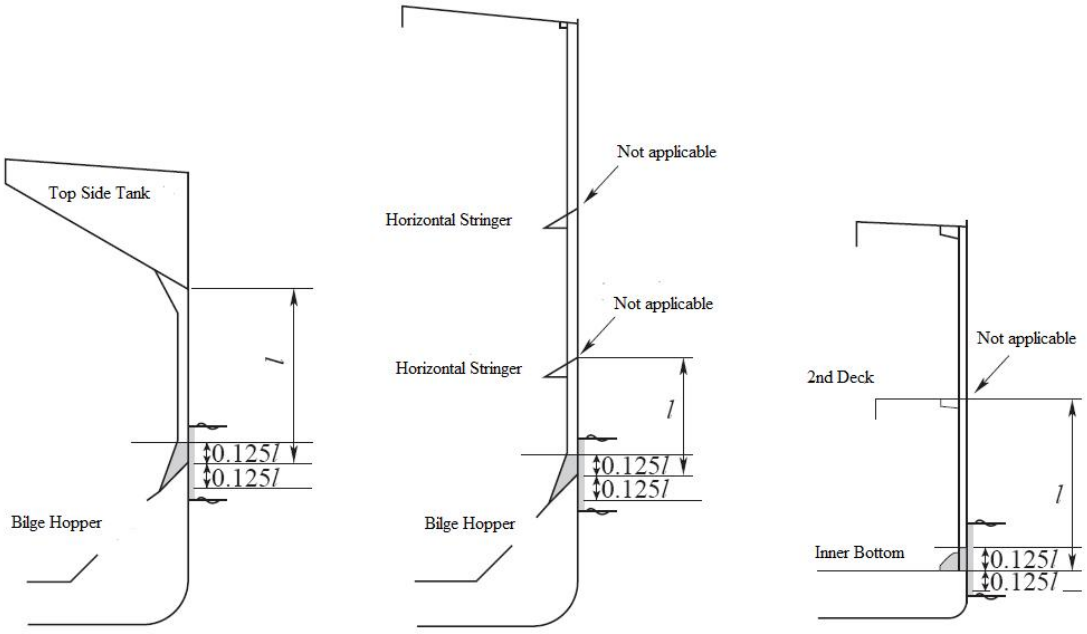

Figure 8.15.2.1

8.15.3 Lateral buckling of stiffeners

8.15.3.1 Scope of check

The lateral buckling of longitudinal and transverse stiffeners in the following areas within cargo areas are to be checked:

(1) hatchway coaming;
(2) inner bottom;
(3) sloped stiffened panel of topside tanks and hopper tanks (if any);
(4) inner side (if any);
(5) top stool and bottom stool of transverse bulkhead (if any);
(6) stiffened transverse bulkhead (if any);
(7) side shell (if directly bounding the cargo hold).

8.15.3.2 Design loads

(1) Design loads are to be based on the loading conditions under intact stability as specified in the loading manual. The loads and loading conditions, for which the strength requirements in 8.15.3.1 are applicable, are given in 8.15.3.2(2).

(2) Loads and load cases

① The following types of loads, if applicable, are to be considered:

(a) normal stress σ_n due to bending of hull girder, see ② below;

(b) shear stress τ_{SF}, see ③ below;

(c) lateral pressure applied to the member in loading conditions under intact stability as specified in the loading manual, see ④ below.

② Normal stress σ_n — the normal stress σ_n considered for each of the mutually exclusive load cases is the maximum compressive stress in the sagging or hogging condition as calculated according to 2.2.5.5 of Chapter 2 of this PART.

③ Shear stress τ_{SF} — the shear stress τ_{SF} considered for each of the mutually exclusive load cases is the shear stress calculated according to 2.2.6.4 of Chapter 2 of this PART.

If the value of the permissible still water shear force is not available at the preliminary design stage, the following value, in kN, may be used:

$$F_s = 0.3CLB(C_B + 0.7)$$

④ Lateral pressure p — the lateral pressure for each of the mutually exclusive load cases is to be selected according to 1.5.3, 1.5.4 and 1.5.5 of Section 5 of Chapter 1 of this PART. The lateral pressure of hatch coaming stiffeners is to be calculated according to 2.20.2.2 of Chapter 2 of this PART.

⑤ The load calculation point for normal stress, shear stress and lateral pressure of stiffener and its

attached plating is defined in Section 7, Chapter 3 of PART 9-1 of the Rules.

⑥ The lateral buckling strength is to be checked for the following two stress combinations:

(a) stress combination 1: 100% of the normal stress as defined in 8.15.3.2(2)② and 70% of the shear stress as defined in 8.15.3.2(2)③;

(b) stress combination 2: 70% of the normal stress as defined in 8.15.3.2(2)② and 100% of the shear stress as defined in 8.15.3.2(2)③.

8.15.3.3 Methods and criteria for check of buckling strength

The lateral buckling capacity of stiffeners is to be calculated according to 2.1 and 2.3 of Section 5, Chapter 8 of Part 9-1 of the Rules, with the safety factor S being taken as 1.15 (i.e. the allowable utilization factor being 0.87). The standard thickness deduction specified in Table 2.2.7.4 of Chapter 2 of this PART is to be deducted in calculation. The buckling strength of stiffeners is to be checked according to the criteria specified in 3.3.1 of Section 3, Chapter 8 of Part 9-1.

Appendix 1 DIRECT STRENGTH CALCULATION OF BULK CARRIERS

1 General

1.1 General requirements

1.1.1 This Appendix applies to the direct strength calculation of bulk carriers as required by this Chapter.

1.1.2 For those not covered in this Appendix, the relevant requirements of Section 5, Chapter 1 of this PART are to be complied with.

2 Design Loads

2.1 General requirements

2.1.1 Unless otherwise specified in this Appendix, the design loads are to be referred to in Section 5, Chapter 1 of this PART.

2.1.2 Unless otherwise specified in this Appendix, the still water bending moment in the global load condition is to be taken as the permissible value $\overline{M}_s$ provided by the designer, and the wave bending moment M_w is to be calculated according to 1.5.6.1(2) of Section 5, Chapter 1 of this PART.

2.1.3 For harbour conditions, the effect of wave loads (pressure and bending moment) is not considered; the allowable still water bending moment $\overline{M}_{sp}$ is determined by the designer, but it is to envelop the design still water bending moment under the loading and unloading conditions in harbour given in the loading manual. The sequence of loading and unloading is to be indicated in the loading manual.

3 Loading Conditions

3.1 General requirements

3.1.1 Normally, the loading conditions under consideration are to cover the most severe condition in ship design. The corresponding loading conditions are to be selected from Table 3.2.1 of this Appendix for check. For more severe loading conditions in the loading manual which are not covered by the Table, direct strength analysis is also to be carried out.

3.2 Loading conditions

3.2.1 The finite element analysis for holds is to be carried out in accordance with the applicable loading conditions in Table 3.2.1.

Loading Conditions **Table 3.2.1**

Type of loading condition	Loading condition no.	Condition considered	Mode of loading	Still water bending moment	Wave bending moment
Full load	1	Full load	Draught = d	$\overline{M}_s$	M_w
	2	Full load	 Draught = d	$\overline{M}_s$	M_w
	3	Non-homogeneous full load		1.1 M_a, but need not be greater than $\overline{M}_s$, taken as $\overline{M}_s$ if there is no such loading	M_w

Type of loading condition	Loading condition no.	Condition considered	Mode of loading	Still water bending moment	Wave bending moment
			 Draught = d	condition	
Ballast	4	Normal ballast	 Draught = deepest ballast draught	$\overline{M}_s$	M_w
	5	Heavy ballast	 Draught = heavy draught	$\overline{M}_s$	M_w
	6	Heavy ballast	 Draught = heavy draught	$\overline{M}_s$	M_w
Alternate load	7	Alternate load	 Draught = d	$\overline{M}_s$	M_w
	8	Alternate load	Draught = d	$\overline{M}_s$	M_w
	9	Alt-block load	 Draught = d	$\overline{M}_s$	M_w
Loading/ Unloading in multiple ports	10	Multi port - 1	 Draught = 0.67d	$\overline{M}_s$	M_w
	11	Multi port - 2		$\overline{M}_s$	M_w

Type of loading condition	Loading condition no.	Condition considered	Mode of loading	Still water bending moment	Wave bending moment
			 Draught = 0.83d		
	12	Multi port – 3a	 Draught = 0.67d	$\overline{M}_s$	M_w
	13	Multi port – 3b	 Draught = 0.67d	$\overline{M}_s$	M_w
	14	Multi port - 4	 Draught = 0.75d	$\overline{M}_s$	M_w
Loading/ Unloading in harbour	15	Harbour condition -1a	 Draught = 0.67d	$\overline{M}_{sp}$	—
	16	Harbour condition - 1b	 Draught = 0.67d	$\overline{M}_{sp}$	—
	17	Harbour condition - 1c	 Draught = 0.67d	$\overline{M}_{sp}$	—
	18	Harbour condition - 2	 draught=0.67d	$\overline{M}_{sp}$	—

Notes:

M_a — actual still water bending moment in the corresponding condition, in kN·m;

M_H — actual cargo mass in a cargo hold corresponding to a homogeneously loaded condition at maximum draught, in t;

M_{FULL} — cargo mass in a cargo hold corresponding to cargo with virtual density filled to the top of the hatch coaming, in t, i.e.:

$$M_{FULL} = V_{FULL} \bullet \max(M_H / V_{FULL}, 1.0)$$

M_{HD} — maximum cargo mass allowed to be carried in a cargo hold according to design loading condition with specified holds empty at maximum draught, in t;

M_{BW} — maximum ballast water mass in cargo holds, in t;

M_{BLK} — maximum cargo mass under packed cargo conditions, in t;

V_H — volume, in m^3, of cargo hold excluding the volume enclosed by hatch coaming;

V_{FULL} — volume, in m^3, of cargo hold including the volume enclosed by hatch coaming;

ρ_w — density of sea water, to be taken as 1.025 t/m^3.

4 Structural Modeling

4.1 General requirements

4.1.1 Unless otherwise specified in this Appendix, the requirements for structural modeling are to be referred to in Section 5, Chapter 1 of this PART (for typical finite element model, see Figure 4.1.1).

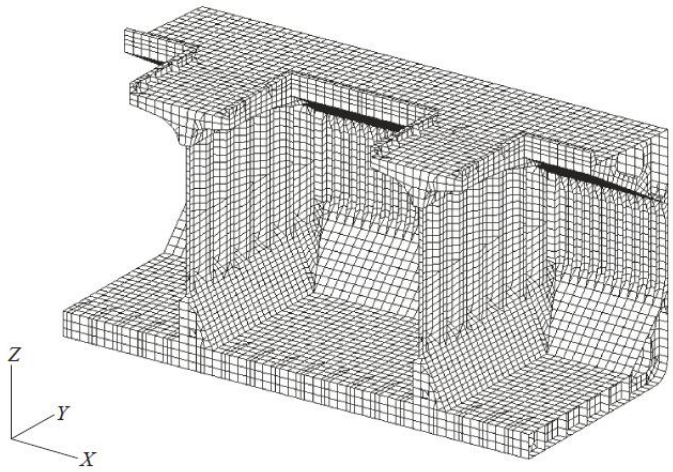

Figure 4.1.1 Finite Element Model

4.2 Boundary conditions

4.2.1 Boundary condition with the structures symmetrical to longitudinal centerline section

4.2.1.1 If a half-breadth FE model is used, the displacements in transverse direction of nodes on the longitudinal centerline section and the rotation around the two coordinate axes on the longitudinal centerline section are restrained, i.e.: $\delta_y = \theta_x = \theta_z = 0$.

4.2.1.2 If a full-breadth FE model is used, the displacements in transverse direction of intersection G of the longitudinal centerline section in way of forward and aft bulkheads of midship cargo holds and bottom plating are restrained, i.e.: $\delta_y = 0$.

4.2.2 Boundary conditions for local loads (see Table 4.2.2)

4.2.2.1 Symmetrical boundary conditions are applied respectively to end planes *A* and *B*, and the displacements in longitudinal direction of nodes within the end plane and the rotations around the two coordinate axes within the end plane are restrained, i.e.: $\delta_x = \theta_y = \theta_z = 0$.

4.2.2.2 Vertical spring elements are to be provided at intersections of side shell plating and inner hull plating with forward and aft transverse bulkheads in midship holds. The coefficient of elasticity of spring elements is to be distributed evenly and calculated by the following formula:

$$K = \frac{5GA}{6l_H n} \quad \text{N/mm}$$

where: G — shear modulus of elasticity of material, $G = 0.792 \times 10^5$ N/mm^2 for steel;

A — shearing area of side shell plating and inner hull plating in way of forward and aft bulkheads, in mm^2;

l_H — length of midship hold, in mm;
n — number of nodes on vertical intersections of side shell plating and inner hull plating.

Boundary Conditions for Local Loads **Table 4.2.2**

Position	Displacement constraint			Rotation constraint		
	δ_x	δ_y	δ_z	θ_x	θ_y	θ_z
Longitudinal centerline section (half-breadth model)	–	Constraint	–	Constraint	–	Constraint
Node *G* (full-breadth model)	–	Constraint	–	–	–	–
End planes *A*, *B*	Constraint	–	–	–	Constraint	Constraint
Intersection line *C*	–	–	Spring	–	–	–

4.2.3 Boundary conditions for global load (see Table 4.2.3)
4.2.3.1 An independent point *H* is to be set in way of intersection of the neutral axis with the longitudinal centerline section within end planes *A* and *B*, the longitudinal bending moment is to be applied on the point *H*, and the degrees of freedom δ_x, δ_y and δ_z of each member node for end planes is linked to independent point.
4.2.3.2 The displacements of the independent point *H* within end planes *A* and *B* in transverse direction, vertical direction, and the rotation around longitudinal axes are restrained, i.e.: $\delta_y = \delta_z = \theta_x = 0$; the displacement of the independent point *H* within the end plane *A* in longitudinal direction are restrained, i.e.: $\delta_x = 0$.

Boundary Conditions for Global Load **Table 4.2.3**

Position	Displacement constraint			Rotation constraint		
	δ_x	δ_y	δ_z	θ_x	θ_y	θ_z
Longitudinal centerline section (half-breadth model)	–	Constraint	–	Constraint	–	Constraint
Node *G* (full-breadth model)	–	Constraint	–	–	–	–
End planes *A*, *B*	Link	Link	Link	–	–	–
Independent point *H* (end plane *A*)	Constraint	Constraint	Constraint	Constraint	Bending moment	–
Independent point *H* (end plane *B*)	–	Constraint	Constraint	Constraint	Bending moment	–

4.2.4 For boundary conditions of the model, see Figure 4.2.4.

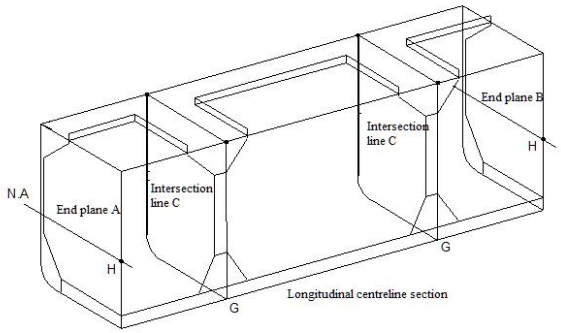

Figure 4.2.4 Boundary Conditions

5 Yield Strength Evaluation

5.1 Allowable stresses

5.1.1 Strength evaluation is to be carried out for all primary members in the cargo holds amidships (including bulkheads) within the longitudinal extent. The stress evaluated is to be the combined one due to local load case and global load case in accordance with 1.5.1.9(2) of Chapter 1 of this PART.

5.1.2 The allowable stresses for each primary structural member are given in Table 5.1.2.

Allowable Stresses **Table 5.1.2**

Type of structures	Allowable stress (N/mm^2)	
	$[\sigma_e]$	$[\tau]$
Deck	220/K	–
Bottom shell plating, inner bottom plating	220/K	–
Side shell plating, inner skin plating, horizontal girder in double hulls	220/K	115/K
Hopper and topside tank sloping plating	220/K	115/K
Bottom girder	235/K	115/K
Double bottom floor	175/K	95/K
Transverse bulkhead	175/K	95/K
Side plating of lower and upper stools	195/K	95/K
Transverse web frame	195/K	95/K
Deck between hatchways	175/K	–
Other	195/K	–

Note: *K*— material factor.

6 Buckling Strength Evaluation

6.1 Buckling safety factors

6.1.1 The standard thickness deduction of members is given in Table 6.1.1.

Standard Thickness Deduction **Table 6.1.1**

Position		Standard thickness deduction (mm)
Within 1.5 m below weather deck	One side connected to ballast water	1.0
	Two sides connected to ballast water	2.0
Elsewhere		1.0

6.1.2 The safety factor λ against plate panel buckling is not to be less than the minimum one in Table 6.1.2.

Minimum Buckling Safety Factor **Table 6.1.2**

Structural member	Minimum buckling safety factors	Structural member	Minimum buckling safety factors
Deck, deck between hatchways	0.8	Double bottom girder, horizontal girder in double hulls	1.0
Bottom shell plating, inner bottom plating	0.8	Double bottom floor, transverse web frame	1.0
Side shell plating, inner skin plating	0.8	Transverse bulkhead, lower stool, upper stool	0.8
Hopper and topside tank sloping plating	0.8		

Appendix 2 HOLD MASS CURVES

Symbols

h : vertical distance from the top of inner bottom plating to upper deck plating at the ship's centerline section, in m;

h_a : vertical distance from the top of inner bottom plating to upper deck plating at the ship's centerline section of aft cargo holds under the alt-block loading condition, in m;

h_f : vertical distance from the top of inner bottom plating to upper deck plating at the ship's centerline section of forward cargo holds under the alt-block loading condition, in m;

M_H : see Appendix 1 of this Chapter;

M_{FULL} : see Appendix 1 of this Chapter;

M_{HD} : see Appendix 1 of this Chapter;

M_D : maximum cargo mass given for each cargo hold, in t;

M_{BLK} : see Appendix 1 of this Chapter;

T_{HB} : maximum ballast draught, in m;

T_i : draught in loading condition No. i at mid-hold position of cargo hold length l_H, in m;

d : draught, in m;

V_H : volume, in m^3, of cargo hold excluding the volume enclosed by hatch coaming;

V_f, V_a : volume, in m^3, of forward or aft cargo hold excluding the volume enclosed by hatch coaming;

T_{min} : 0.75 d or draught in ballast conditions with the two adjacent cargo holds empty, whichever is greater, in m;

Σ : sum of mass of two adjacent cargo holds.

1 General Requirements

1.1 Application

1.1.1 This Appendix applies to ships of 150 m or over in length.

1.1.2 This Appendix describes the procedure to be used for determination of:

(1) the maximum and minimum masses of cargo in each cargo hold as a function of the draught at mid-hold position of cargo hold;

(2) the maximum and minimum mass of cargo in any two adjacent holds as a function of the mean draught in way of these holds.

1.1.3 The calculation results are to be included in the loading manual.

2 Maximum and Minimum Masses of Cargo in Each Hold

2.1 Maximum permissible mass and minimum required mass of single cargo hold in sea-going condition

2.1.1 The cargo mass curves of single cargo hold in sea-going condition are defined in 2.1.2 to 2.1.5 of this Appendix. However, if the ship structure is checked for more severe loading conditions than the ones considered in Appendix 1 of this Chapter, the minimum required cargo mass and maximum permissible cargo mass may be based on those more severe loading conditions.

2.1.2 Ships with alternate load under multi-port condition

For loaded holds, the maximum permissible cargo mass ($W_{max}(T_i)$) at various draughts (T_i) is obtained, in t, by the following formulae:

$$W_{\max}(T_i) = M_{HD} + 0.1M_H - 1.025V_H \frac{(d - T_i)}{h}$$

$W_{max}(T_i)$ in no case to be greater than M_{HD}.

For loaded holds, the minimum required cargo mass ($W_{min}(T_i)$) at various draughts (T_i) is obtained, in t, by the following formulae:

$$W_{\min}(T_i) = 0 \qquad \text{for } T_i \le 0.83d$$

$$W_{\min}(T_i) = 1.025V_H \frac{(T_i - 0.83d)}{h} \qquad \text{for } d \ge T_i > 0.83d$$

For empty holds which may be empty at the maximum draught, the maximum permissible cargo mass ($W_{max}(T_i)$) at various draughts (T_i) is obtained, in t, by the following formulae:

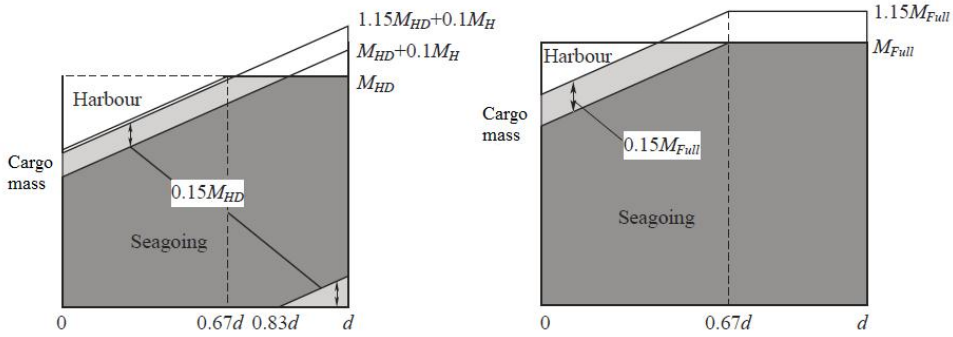
$$W_{\max}(T_i) = M_{Full} \qquad \text{for } d \ge T_i \ge 0.67d$$

$$W_{\max}(T_i) = M_{Full} - 1.025V_H \frac{(0.67d - T_i)}{h} \quad \text{for } T_i < 0.67d$$

For loaded holds, the minimum required cargo mass ($W_{min}(T_i)$) at various draughts (T_i) is obtained, in t, by the following formula:

$$W_{\min}(T_i) = 0 \quad \text{for } T_i \le d$$

Mass curves of loaded cargo hold and cargo hold which may be empty at the maximum draught for ships with alternate load under multi-port condition are shown in Figure 2.1.2.



(a) Loaded hold (b) Cargo hold which may be empty at the maximum draught

Figure 2.1.2 Mass Curve for Ships with Alternate Load under Multi-port Condition

2.1.3 Ships with alternate load under no multi-port condition

For cargo holds, the maximum permissible cargo mass ($W_{max}(T_i)$) at various draughts (T_i), in t, is the same as specified in 2.1.2.

For cargo holds, the minimum required cargo mass ($W_{min}(T_i)$) at various draughts (T_i) is obtained, in t, by the following formulae:

$$W_{\min}(T_i) = 0 \quad \text{for } T_i \le T_{HB}$$

$$W_{\min}(T_i) = \min \begin{cases} 1.025V_H \dfrac{(T_i - T_{HB})}{h} & \text{for } d \ge T_i > T_{HB} \\ 0.5M_{\mathrm{H}} - 1.025V_{\mathrm{H}} \dfrac{(d - T_{\mathrm{i}})}{h} \geqslant 0 & \text{for } d \ge T_i \end{cases}$$

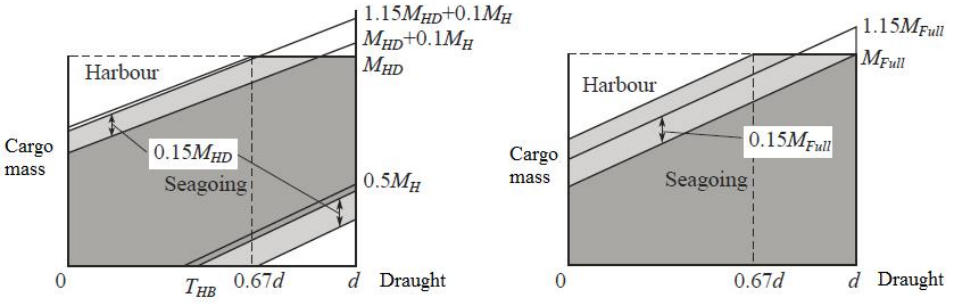
For empty hold which may be empty at the maximum draught, the maximum permissible cargo mass ($W_{max}(T_i)$) at various draught (T_i) is obtained, in t, by the following formula:

$$W_{\max}(T_i) = M_{Full} - 1.025V_H \frac{(d - T_i)}{h}$$

For empty hold which may be empty at the maximum draught, the minimum required cargo mass ($W_{min}(T_i)$) at various draught (T_i) is obtained, in t, by the following formula:

$$W_{\min}(T_i) = 0 \quad \text{for } T_i \le d$$

Mass curves of loaded cargo hold and cargo hold which may be empty at the maximum draught for ships with alternate load under no multi-port condition are shown in Figure 2.1.3.



(a) Loaded hold (b) Cargo hold which may be empty at the maximum draught

Figure 2.1.3 Mass Curve for Ships with Alternate Load under no Multi-port Condition

2.1.4 Ships with homogeneous load under multi-port condition

The maximum permissible cargo mass ($W_{max}(T_i)$) at various draughts (T_i) is obtained, in t, by the following

formulae:

$$W_{\max}(T_i) = M_{Full} \qquad \text{for } d \geq T_i \geq 0.67d$$

$$W_{\max}(T_i) = M_{Full} - 1.025V_H \frac{(0.67d - T_i)}{h} \qquad \text{for } T_i < 0.67d$$

The minimum required cargo mass ($W_{min}(T_i)$) at various draughts (T_i) is obtained, in t, by the following formulae:

$$W_{\min}(T_i) = 0 \qquad \text{for } T_i \leq 0.83d$$

$$W_{\min}(T_i) = 1.025V_H \frac{(T_i - 0.83d)}{h} \qquad \text{for } d \geq T_i > 0.83d$$

Mass curves of loaded cargo hold for ships with homogeneous load under multi-port condition are shown in Figure 2.1.4.

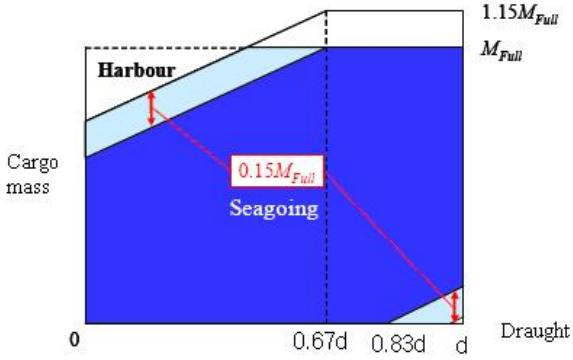


Figure 2.1.4 Mass Curve for Ships with Homogeneous Load under Multi-port Condition

2.1.5 Ships with homogeneous load under no multi-port condition

The maximum permissible cargo mass ($W_{max}(T_i)$) at various draughts (T_i) is obtained, in t, by the following formula:

$$W_{\max}(T_i) = M_{Full} - 1.025V_H \frac{(d - T_i)}{h}$$

The minimum required cargo mass ($W_{min}(T_i)$) at various draughts (T_i) is obtained, in t, by the following formulae:

$$W_{\min}(T_i) = 0 \qquad \text{for } T_i \leq T_{HB}$$

$$W_{\min}(T_i) = \min \begin{cases} 1.025V_H \dfrac{(T_i - T_{HB})}{h} \geqslant 0 & \text{for } d \geq T_i > T_{HB} \\ 0.5M_{\mathrm{H}} - 1.025V_{\mathrm{H}} \dfrac{(d - T_{\mathrm{i}})}{h} \geqslant 0 & \text{for } d \geq T_i \end{cases}$$

Mass curves of loaded cargo hold for ships with homogeneous load under no multi-port condition are shown in Figure 2.1.5.

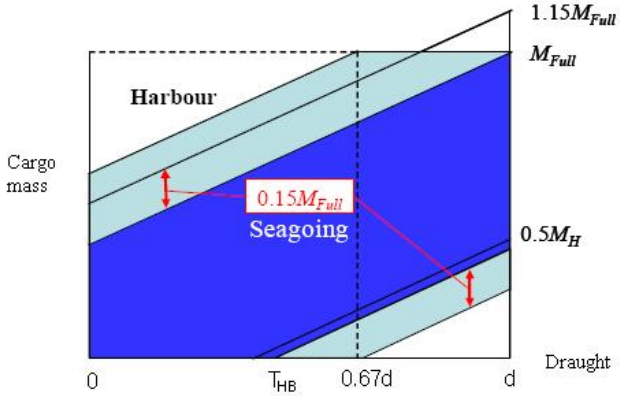

Figure 2.1.5 Mass Curve for Ships with Homogeneous Load under No Multi-port Condition

2.2 Maximum permissible mass and minimum required mass of single cargo hold in harbour

condition

2.2.1 The cargo mass curves of single cargo hold in harbour condition are defined in 2.2.2 of this Appendix. However, if the ship structure is checked for more severe loading conditions than the ones considered in Appendix 1 of this Chapter, the minimum required cargo mass and maximum permissible cargo mass may be based on those more severe loading conditions.

2.2.2 For all ships, the maximum permissible cargo mass and the minimum required cargo mass corresponding to draught for loading/unloading conditions in harbour may be increased or decreased by 15% of the maximum permissible mass at the maximum draught for the cargo hold in sea-going condition. Maximum permissible cargo mass is in no case to be greater than the maximum permissible cargo mass at designed maximum load draught for each cargo hold.

2.2.3 Ships with alternate load under multi-port condition

During the loading/unloading in harbour, the maximum permissible cargo mass ($W_{max}(T_i)$), in t, at various draughts (T_i) is to be checked by the following formulae, in addition to the requirements of 2.1.2 of this Appendix:

For cargo hold,

$$W_{\max}(T_i) = M_{HD} \qquad \text{for } T_i \geq 0.67d$$

$$W_{\max}(T_i) = M_{HD} - 1.025V_H \frac{(0.67d - T_i)}{h} \qquad \text{for } T_i < 0.67d$$

2.2.4 Ships with alternate load under no multi-port condition

During the loading/unloading in harbour, the maximum permissible cargo mass ($W_{max}(T_i)$), in t, at various draughts (T_i) is to be checked by the following formulae, in addition to the requirements of 2.1.3 of this Appendix:

For empty hold which may be empty at the maximum draught,

$$W_{\max}(T_i) = M_{FULL} \qquad \text{for } T_i \geq 0.67d$$

$$W_{\max}(T_i) = M_{FULL} - 1.025V_H \frac{(0.67d - T_i)}{h} \qquad \text{for } T_i < 0.67d$$

2.2.5 Ships with homogeneous load under no multi-port condition

During the loading/unloading in harbour, the maximum permissible cargo mass ($W_{max}(T_i)$), in t, at various draughts (T_i) is to be checked by the following formulae, in addition to the requirements of 2.2.2 of this Appendix:

$$W_{\max}(T_i) = M_{FULL} \qquad \text{for } d \geq T_i > 0.67d$$

$$W_{\max}(T_i) = M_{FULL} - 1.025V_H \frac{(0.67d - T_i)}{h} \qquad \text{for } T_i < 0.67d$$

3 Maximum and Minimum Cargo Masses of Two Adjacent Holds

3.1 Maximum permissible cargo mass and minimum required cargo mass of two adjacent holds in sea-going condition

3.1.1 The cargo mass curves of two adjacent cargo holds in sea-going condition are defined in 3.1.2 of this Appendix. However, if the ship structure is checked for more severe loading conditions than the ones considered in Appendix 1 of this Chapter, the minimum required cargo mass and maximum permissible cargo mass may be based on those more severe loading conditions.

3.1.2 Ships with alternate load of bulk goods under multi-port condition

The maximum permissible mass cargo ($W_{max}(T_i)$) at various draughts (T_i) is obtained, in t, by the following formulae:

$$W_{\max}(T_i) = \sum (M_{BLK} + 0.1M_H) - 1.025\left(\frac{V_f}{h_f} + \frac{V_a}{h_a}\right)(d - T_i)$$

or

$$W_{\max}(T_i) = \sum M_{FULL} - 1.025\left(\frac{V_f}{h_f} + \frac{V_a}{h_a}\right)(0.67d - T_i)$$

$W_{\max}(T_i)$ is not greater than $\sum M_{BLK}$.

The minimum required cargo mass ($W_{min}(T_i)$) at various draughts (T_i) is obtained, in t, by the following formulae:

$$W_{\min}(T_i) = 0 \qquad \text{for } T_i \leq 0.75d$$

$$W_{\min}(T_i) = 1.025(\frac{V_f}{h_f} + \frac{V_a}{h_a})(T_i - 0.75\mathrm{d}) \quad \text{for } d \geq T_i > 0.75d.$$

3.1.3 Ships with alternate load of packed cargo under no multi-port condition

The maximum permissible cargo mass ($W_{max}(T_i)$) at various draughts (T_i) is obtained, in t, by the following formulae:

$$W_{\max}(T_i) = \sum(M_{BLK} + 0.1M_H) - 1.025(\frac{V_f}{h_f} + \frac{V_a}{h_a})(d - T_i)$$

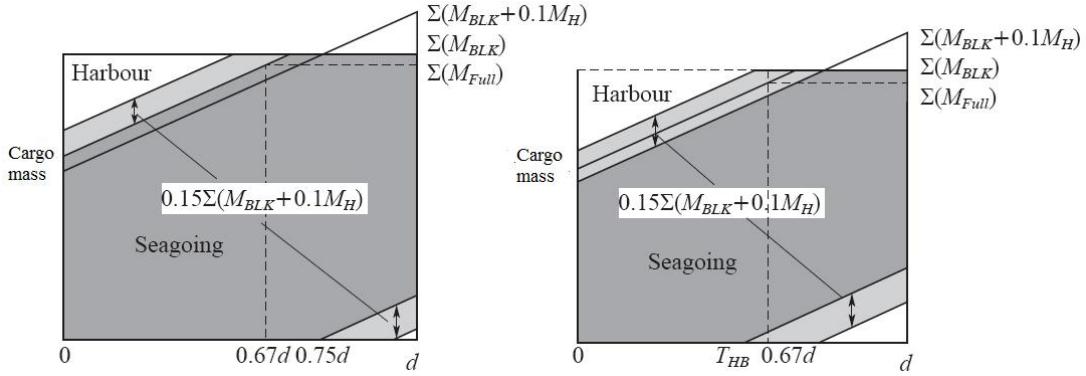
$W_{\max}(T_i)$ is not greater than $\sum M_{BLK}$.

The minimum required cargo mass ($W_{min}(T_i)$) at various draughts (T_i) is obtained, in t, by the following formulae:

$$W_{\min}(T_i) = 0 \qquad \text{for } T_i \leq T_{HB}$$

$$W_{\min}(T_i) = 1.025(\frac{V_f}{h_f} + \frac{V_a}{h_a})(T_i - T_{HB}) \quad \text{for } d \geq T_i > T_{HB}.$$

Mass curves of loaded cargo hold for ships with alternate load of packed cargo are shown in Figure 3.1.3.



(a) Under multi-port condition (b) Under no multi-port condition

Figure 3.1.3 Mass Curve of Loaded Cargo Hold for Ships with Alternate Load of Packed Cargo

3.1.4 Ships with alternate load without packed cargo under multi-port condition and ships with homogeneous load

The maximum permissible mass cargo ($W_{max}(T_i)$) at various draughts (T_i) is obtained, in t, by the following formulae:

$$W_{\max}(T_i) = \sum M_{FULL} \qquad \text{for } d \geq T_i \geq 0.67d$$

$$W_{\max}(T_i) = \sum M_{FULL} - 1.025(\frac{V_f}{h_f} + \frac{V_a}{h_a})(0.67d - T_i) \qquad \text{for } T_i < 0.67d$$

The minimum required cargo mass ($W_{min}(T_i)$) at various draughts (T_i) is obtained, in t, by the following formulae:

$$W_{\min}(T_i) = 0 \qquad \text{for } T_i \leq 0.75d$$

$$W_{\min}(T_i) = 1.025(\frac{V_f}{h_f} + \frac{V_a}{h_a})(T_i - 0.75\mathrm{d}) \qquad \text{for } d \geq T_i > 0.75d$$

3.1.5 Ships with alternate load without packed cargo under no multi-port condition and ships with homogeneous load

The maximum permissible mass cargo ($W_{max}(T_i)$) at various draughts (T_i) is obtained, in t, by the following formula:

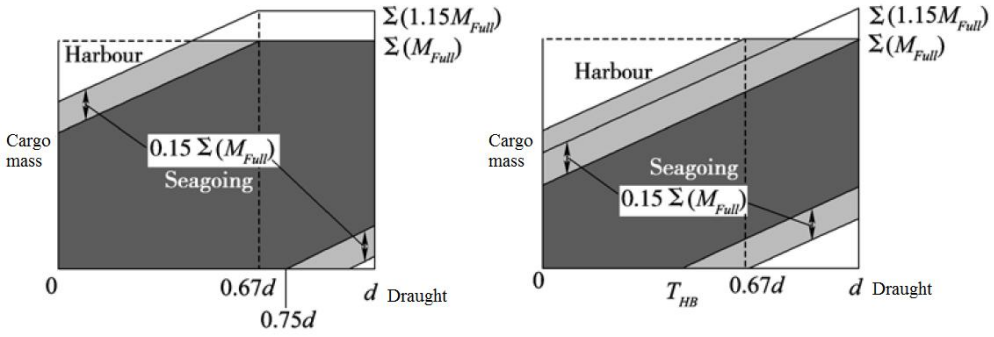
$$W_{\max}(T_i) = \sum M_{FULL} - 1.025(\frac{V_f}{h_f} + \frac{V_a}{h_a})(d - T_i) \qquad \text{for } T_i < d$$

The minimum required cargo mass ($W_{min}(T_i)$) at various draughts (T_i) is obtained, in t, by the following formulae:

$$W_{\min}(T_i) = 0 \qquad \text{for } T_i \leq T_{HB}$$

$$W_{\min}(T_i) = 1.025(\frac{V_f}{h_f} + \frac{V_a}{h_a})(T_i - T_{HB}) \quad \text{for } d \geq T_i > T_{HB}$$

Mass curves of loaded cargo hold for ships with alternate load without packed cargo are shown in Figure 3.1.5.



(a) Under multi port condition (b) Under no multi port condition

Figure 3.1.5 Mass Curve of Loaded Cargo Hold for Ships with Alternate Load without Packed Cargo and Ships with Homogeneous Load

3.2 Maximum permissible cargo mass and minimum required cargo mass in two adjacent holds in harbour condition

3.2.1 The cargo mass curves of two adjacent cargo holds in harbour condition are defined in 3.2.2 of this Appendix. However, if the ship structure is checked for more severe loading conditions than the ones considered in Appendix 1 of this Chapter, the minimum required cargo mass and maximum permissible cargo mass may be based on those more severe loading conditions.

3.2.2 For all ships, the maximum permissible cargo mass and the minimum required cargo mass corresponding to draught for loading/unloading conditions in harbour may be increased or decreased by 15% of the maximum permissible mass at the maximum draught for the cargo hold in sea-going condition. Maximum permissible cargo mass is in no case to be greater than the maximum permissible cargo mass at designed maximum load draught for each cargo hold.

3.2.3 Ships with alternate load of packed cargo under no multi-port condition

During the loading/unloading in harbour, the maximum permissible cargo mass ($W_{max}(T_i)$), in t, at various draughts (T_i) is to be checked by the following formulae, in addition to the requirements of 3.1.3 of this Appendix:

$$W_{\max}(T_i) = \sum M_{FULL} - 1.025\left(\frac{V_f}{h_f} + \frac{V_a}{h_a}\right)(0.67d - T_i)$$

$$W_{\max}(T_i) \le M_{BLK}$$

3.2.4 Ships with alternate load without packed cargo under no multi-port condition and ships with homogeneous load

During the loading/unloading in harbour, the maximum permissible cargo mass ($W_{max}(T_i)$), in t, at various draughts (T_i) is to be checked by the following formulae, in addition to the requirements of 3.1.5 of this Appendix:

$$W_{\max}(T_i) = M_{FULL} \qquad \text{for } d \ge T_i \ge 0.67d$$

$$W_{\max}(T_i) = \sum M_{FULL} - 1.025\left(\frac{V_f}{h_f} + \frac{V_a}{h_a}\right)(0.67d - T_i) \qquad \text{for } T_i < 0.67d$$

CHAPTER 9 ROLL ON-ROLL OFF SHIPS, PASSENGER SHIPS, RO-RO PASSENGER SHIPS AND FERRIES

Section 1 GENERAL PROVISIONS

9.1.1 Application

9.1.1.1 This Chapter applies to roll on-roll off ships, passenger ships, ro-ro passenger ships and ferries defined as follows:

(1) A roll on-roll off ship is a ship specially designed and constructed for the carriage of vehicles, and cargo in pallet form or in containers, and loaded/unloaded by wheeled vehicles;

(2) A passenger ship is a ship which carries more than twelve passengers;

(3) Ro-ro passenger ship means a passenger ship with ro-ro cargo spaces or special category spaces;

(4) Ferries are the ships specially designed for the carriage of passengers (without sleeping berths) and/or vehicles engaged on regular voyages between two sides of straits or islands. Ferries carrying more than 12 passengers are ferry passenger ships.

9.1.1.2 Ro-ro spaces are spaces not normally subdivided in any way and normally extending to either a substantial length or the entire length of the ship, in which motor vehicles with fuel in their tanks for their own propulsion or goods (packaged or in bulk, in or on rail or road cars, vehicles (including road or rail tankers), trailers, containers, pallets, demountable tanks or in or on similar stowage units or other receptacles) can be loaded and unloaded normally in a horizontal direction.

9.1.1.3 Special category spaces are those enclosed vehicle spaces above and below the bulkhead deck, into and from which vehicles can be driven and to which passengers have access. Special category spaces may be accommodated on more than one deck provided that the total overall clear height for vehicles does not exceed 10 m.

9.1.1.4 Those not specified in this Chapter are to comply with the relevant requirements of Chapter 2 of this PART.

9.1.2 Class notations

9.1.2.1 Ships complying with the requirements of this Chapter will be eligible to be assigned one of the following class notations:

(1) Roll on-roll off ships: RO-RO Ship;

(2) Passenger ships: Passenger Ship;

(3) Ro-ro passenger ships carrying only road vehicles: RO-RO Passenger Ship;

(4) Ro-ro passenger ships carrying railway vehicles: Train/RO-RO Passenger Ship;

(5) Ferries: Ferry;

(6) Ferry Passenger Ship.

9.1.3 Plans and documents

9.1.3.1 In addition to the plans and documents required in Section 1, Chapter 2 of this PART, the following plans and documents are to be submitted for approval:

(1) Structural arrangement of ramps (appropriate strength calculations are submitted for information);

(2) Structural arrangements of bow doors, inner doors, stern doors and side doors and their operating and maintenance manual (appropriate strength calculations are submitted for information);

(3) Structural arrangement of movable platforms (appropriate strength calculations are submitted for information);

(4) Structural arrangement of sloping vehicle ramps (appropriate strength calculations are submitted for information).

9.1.3.2 Direct strength calculations for vehicle deck (where available), direct calculations of transverse strength for hull (where applicable), the arrangement of wheel prints for the carriage of vehicles and the data related to design loading, e.g. loads and axle loads, are to be provided for information.

Section 2 HULL STRUCTURE

9.2.1 General requirements

9.2.1.1 The structural arrangements of the hull are to comply with the relevant requirements of Section 12,

Chapter 1 of this PART.

9.2.1.2 The basic structural configuration is to be a single deck or multi-deck hull, and in some cases wing tanks up to the freeboard deck or bulkhead deck may be fitted.

9.2.1.3 Where the number of transverse bulkheads is not in accordance with the requirements in Section 12, Chapter 2 of this PART, partial transverse bulkheads, or web frames and deck transverses are to be fitted to provide equivalent transverse strength.

9.2.1.4 Longitudinal framing is, in general, to be adopted at the strength deck and at the bottom for ships greater than 65 m in length.

9.2.1.5 Web frames and deck transverses within vehicle spaces above the bulkhead deck may be connected with continuous rounded corners or by cross joints without brackets, see Figure 9.2.1.5(1) and (2). The radius R of the rounded corners is not to be less than the web depth of web frame or deck transverse, whichever is greater. The web thickness t_3 of the joint of cross connection without brackets (between web frame and deck transverse) is not to be less than the greater of the values obtained by the following formulas, nor less than the web thickness of web frame or deck transverse, whichever is greater.

$$t_3 = \frac{1}{K}\left(\frac{\sigma_1 A_1}{d_{w_2}} - \frac{t_2\tau_2}{100}\right) \quad \text{mm}$$

$$t_3 = \frac{1}{K}\left(\frac{\sigma_2 A_2}{d_{w_1}} - \frac{t_1\tau_1}{100}\right) \quad \text{mm}$$

where: A_1, A_2 — sectional area of faceplate respectively of web frame and deck transverse, in cm^2;

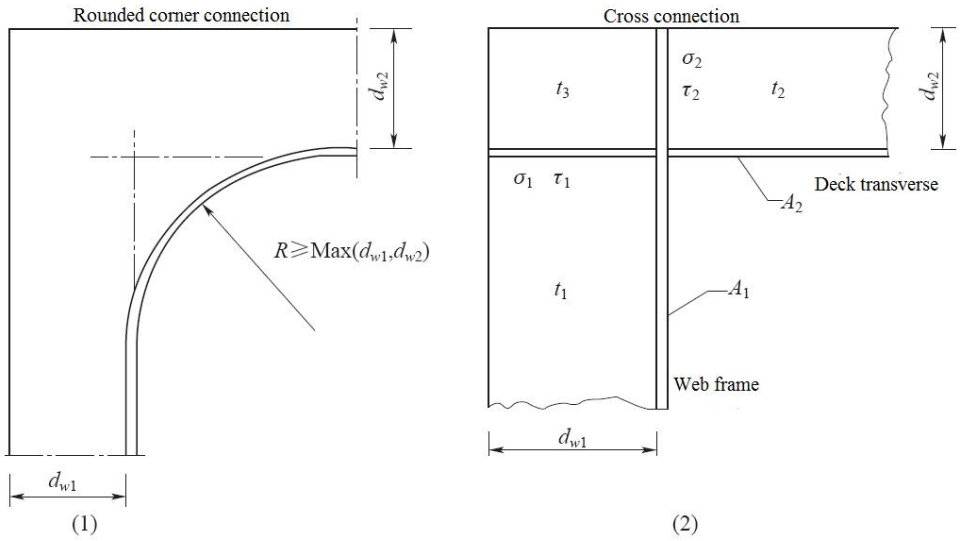
d_{w1}, d_{w2} — web depth respectively of web frame and deck transverse, in mm;

t_1, t_2 — web thickness respectively of web frame and deck transverse adjacent to cross connection joint, in mm;

σ_1, σ_2 — bending stress respectively of web frame and deck transverse adjacent to cross connection joint, in N/mm^2;

τ_1, τ_2 — shear stress respectively of web frame and deck transverse adjacent to cross connection joint, in N/mm^2;

K — material factor.



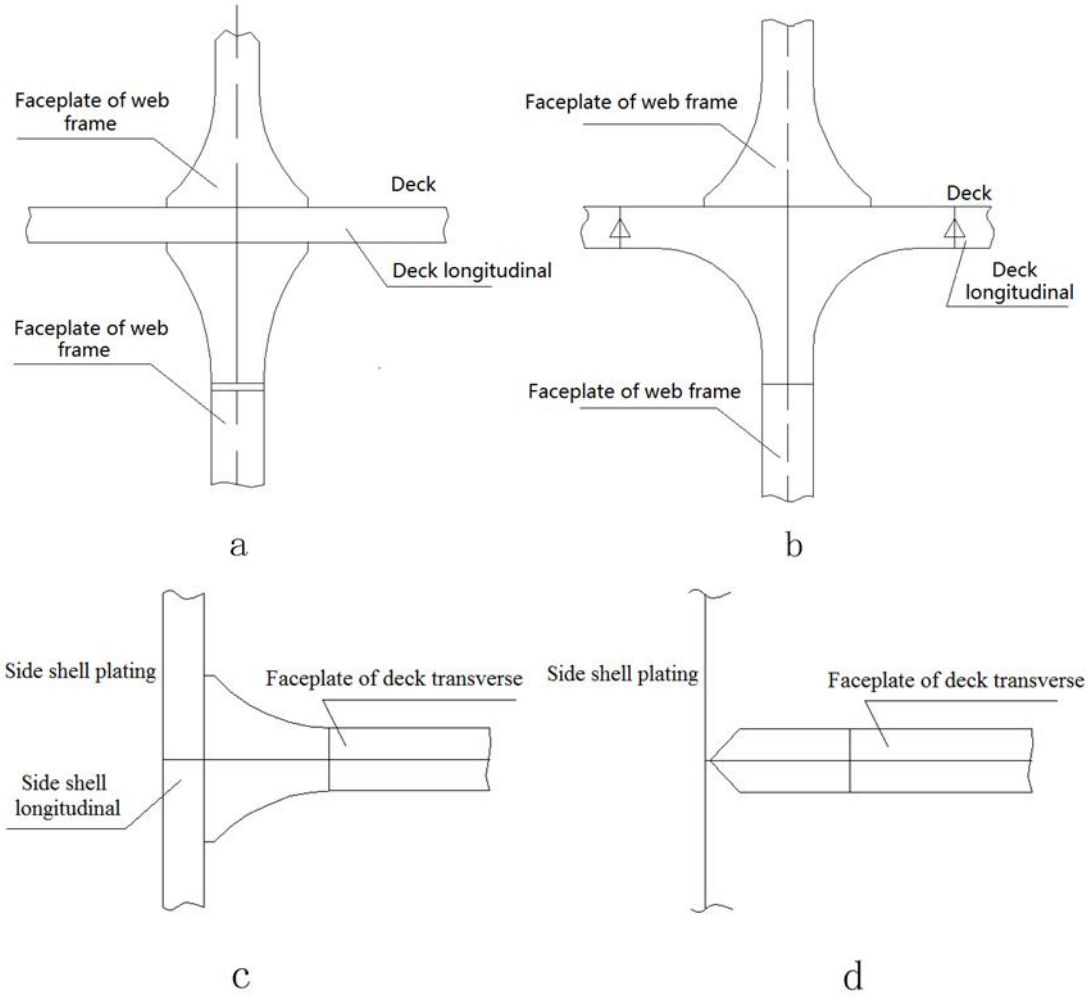


Figure 9.2.1.5

The faceplate of web frames and deck transverses, which are cross-connected without brackets, is to be continuous to deck plating and side shell and to be well transitioned, see Figure 9.2.1.5(3) for typical types of joints.

9.2.1.6 Where necessary, the structures in way of securing devices of vehicles and securing points of the hull are to be locally strengthened as appropriate.

9.2.1.7 The scantlings of stabilizing tanks and balancing tanks are to comply with the requirements of Section 13, Chapter 2 of this PART for deep tanks. The scantlings of those members, which may be subject to sloshing loads, are to be increased by 10%.

9.2.2 Longitudinal strength

9.2.2.1 The longitudinal strength is to comply with the requirements of Section 2, Chapter 2 of this PART. Where large openings are cut in side shell below strength deck and this significantly reduces shear force transmission from side shell to strength deck, the contribution of longitudinal continuous members within the area of strength deck and openings below to the longitudinal strength may be determined by finite element direct calculations.

9.2.3 Transverse strength

9.2.3.1 For roll on-roll off ships, ro-ro passenger ships and ferries carrying vehicles, the transverse strength of the hull is to be checked in accordance with the relevant requirements of Section 7 of this Chapter.

9.2.4 Superstructure deck

9.2.4.1 Where superstructure deck is strength deck, the thickness of deck plating, excluding that of the forecastle, is to comply with the requirements of 2.17.5.4 in Section 17, Chapter 2 of this PART and the buckling strength requirements in respect to longitudinal strength in Section 2 of the same Chapter, but not

less than 6 mm.
9.2.4.2 Where superstructure deck is strength deck, the framing of superstructure deck is to comply with the relevant requirements in Section 8, Chapter 2 of this PART and the buckling strength requirements in respect to longitudinal strength in Section 2 of the same Chapter.

9.2.5 Side framing

9.2.5.1 Side framing is to comply with the relevant requirements of Section 7, Chapter 2 of this PART. When calculating the scantlings of primary members of side framing below freeboard deck, however, the design pressure head may be measured to freeboard deck at side.

9.2.6 Vehicle deck

9.2.6.1 The structure of vehicle deck is to comply with the requirements of Section 21, Chapter 2 of this PART.
9.2.6.2 The strength of primary supporting members of vehicle deck is to comply with relevant requirements in Section 7 of this Chapter.

9.2.7 Train deck

9.2.7.1 Rails on the deck are to be fitted in way of deck girders or longitudinals. The effects of rails on the structural strength are not to be considered.
9.2.7.2 The thickness of deck plating is to be in accordance with the relevant requirements in Section 4, Chapter 2 of this PART.
9.2.7.3 The longitudinals or beams of deck framing are to be in accordance with the relevant requirements in Section 8, Chapter 2 of this PART, and the design head h is to be taken as $0.14p$, p being design cargo load, in kPa. Deck longitudinals supporting rails are to comply with the relevant requirements of Section 21, Chapter 2 of this PART.
9.2.7.4 The girders and transverses of deck framing are to be in accordance with 2.21.2.3 in Section 21, Chapter 2 of this PART. Where the deck framing is fitted with transverses and girders, their scantlings may be determined by direct calculations in accordance with the relevant requirements in Section 7 of this Chapter. The load of train wheels and the concentrated static load at supporting points of lifting jacks are to be taken into account respectively.
9.2.7.5 Where the train deck is intended to carry road vehicles, the relevant requirements in this Chapter for vehicle decks are to be complied with.
9.2.7.6 Where jacks are used to secure trains, the supporting points of the jacks are to be arranged as far as practicable in way of primary supporting members of the deck structure, otherwise the structure in this area is to be locally strengthened as appropriate.

9.2.8 Deck framing within area of deckhouses in accommodation spaces

9.2.8.1 The section modulus W of deck longitudinals or beams within the area of deckhouses is not to be less than the value obtained as follows:

$$W = 5shl^2K \quad \text{cm}^3, \text{ and not less than } 25s$$

where: s — spacing of deck longitudinals or beams, in m;
l — span of deck longitudinals or beams, in m;
h — design head, in m, taken as 0.45 m and for portions exposed to weather, increased by $h_0 - 1.2$ m, where h_0 is to be calculated according to 2.8.1.1 of Chapter 2 of this PART;
K — material factor.

The scantlings of deck girders and transverses within the area of deckhouses are to be calculated in accordance with the relevant requirements in Section 8, Chapter 2 of this PART, while the design head is to be taken as 0.45 m and the web thickness of deckhouse girders is not to be less than 1% of web depth plus 2 mm, nor less than 4 mm.

9.2.9 Deck framing within area of deckhouses in baggage and storage spaces

9.2.9.1 For deck framing within the area of deckhouses, calculations are to be in accordance with the requirements in Section 8, Chapter 2 of this PART for cargo decks not exposed to weather.

Section 3 MOVABLE PLATFORMS AND SLOPING VEHICLE RAMPS

9.3.1 Movable platforms

9.3.1.1 Movable platforms are generally to be constructed as pontoons comprising a web structure with

top decking.

9.3.1.2 Positive means of control are to be provided to secure the platform in the lowered position.

9.3.1.3 The supporting members of movable platforms are to have sufficient strength. For the design of movable platform, the strength of the fittings or members at the following supports is to be checked on the basis of the imposed loads (including the weight of the platform):

(1) Flexible supports: the permissible load for fittings such as chains and steel hawsers is to be taken as 1/5 of the breaking strength;

(2) Rigid supports: the allowable stresses are to be as follows:

Allowable bending stress $[\sigma] \leq 85/K$ N/mm²;

Allowable shear stress $[\tau] \leq 43/K$ N/mm²;

Allowable equivalent stress $[\sigma_e] = \sqrt{\sigma^2 + 3\tau^2} \leq 108/K$ N/mm²

where: K — material factor.

(3) Buckling is to be checked for the pressured members.

9.3.1.4 The thickness of the movable platform plating is to be calculated as that of the vehicle decks.

9.3.1.5 Where the movable platforms are intended for handling cargo with forklifts, the scantlings of the stiffeners are to comply with the requirements for deck beams or longitudinals in Section 21, Chapter 2 of this PART.

9.3.1.6 The section modulus W of the stiffeners of movable platforms designed exclusively for the carriage of vehicles is not to be less than that obtained from the following formula:

$$W = 1.39 J_1 P l K \quad \text{cm}^3$$

where: J_1, P and l — see 2.21.2.2(2) of Chapter 2 of this PART;

K— material factor.

9.3.1.7 The scantlings of girders of movable platforms may be determined by a direct calculation on the basis of the following criteria:

Allowable bending stress: $[\sigma] \leq 128/K$ N/mm²;

Allowable shear stress: $[\tau] \leq 64/K$ N/mm²;

Allowable equivalent stress: $[\sigma_e] = \sqrt{\sigma^2 + 3\tau^2} \leq 160/K$ N/mm²;

Deflection: $f \leq l/400$ mm.

where: K — material factor;

l — distance between the supporting points of stiffeners, in mm.

9.3.2 Sloping vehicle ramps

9.3.2.1 Fixed sloping vehicle ramps are to comply with the requirements for vehicle decks in Section 21, Chapter 2 of this PART.

9.3.2.2 Movable sloping vehicle ramps are to comply with the requirements for vehicle ramps in Section 6 of this Chapter, and their rigid supports are to comply with 9.3.1.3(2) of this Section.

Section 4 BOW DOORS AND INNER DOORS

9.4.1 General requirements

9.4.1.1 Application

(1) This Section applies to the arrangement, strength and securing of bow doors and inner doors leading to a complete or long forward enclosed superstructure, or to a long non-enclosed superstructure which is fitted to attain minimum bow height equivalence.

(2) This Section is applicable to the following two types of bow doors:

① Visor doors opened by rotating upwards and outwards about a horizontal axis through two or more hinges located near the top of the door and connected to the primary structure of the door by longitudinally arranged lifting arms;

② Side-opening doors opened either by rotating outwards about a vertical axis through two or more hinges located near the outboard edges or by horizontal translation by means of linking arms arranged with pivoted attachments to the door and the ship. It is anticipated that side-opening bow doors are arranged in pairs.

Other types of bow door will be specially considered.

9.4.1.2 Arrangement

(1) Bow doors are to be situated above the freeboard deck. A watertight recess in the freeboard deck located forward of the collision bulkhead and above the deepest waterline, fitted for arrangement of ramps

or other related mechanical devices, may be regarded as a part of the freeboard deck for the purpose of this requirement.
(2) An inner door is to be fitted. The inner door is to be part of the collision bulkhead. The inner door need not be fitted directly above the bulkhead, provided it is located within the limits specified for the position of the collision bulkhead (1.12.3.1 or 1.12.3.2 of Section 12, Chapter 1 of this PART). A vehicle ramp may be arranged for this purpose at the position specified in 1.12.3.1 or 1.12.3.2 of Section 12, Chapter 1 of this PART. If this is not possible, a separate inner weathertight door is to be installed, as far as practicable, within the limits specified for the position of the collision bulkhead.
(3) Bow doors are to be so fitted as to ensure tightness consistent with operational conditions and to give effective protection to inner doors. Inner doors forming part of the collision bulkhead are to be weathertight over the full height of the cargo space and arranged with fixed sealing supports on the aft side of the doors.
(4) Bow doors and inner doors are to be arranged so as to preclude the possibility of the bow door causing structural damage to the inner door or to the collision bulkhead in the case of damage to or detachment of the bow door. If this is not possible, a separate inner weathertight door is to be installed, as indicated in 9.4.1.2(2) of this Section.
(5) The requirements for inner doors are based on the assumption that vehicles are effectively lashed and secured against movement in stowed position.
9.4.1.3 Definitions
(1) **Securing device**: a device used to keep the door closed by preventing it from rotating about its hinges;
(2) **Supporting device**: a device used to transmit external or internal loads from the door to a securing device and from the securing device to the ship's structure, or a device other than a securing device, such as a hinge, stopper or other fixed device, that transmits loads from the door to the ship's structure;
(3) **Locking device**: a device that locks a securing device in the closed position;
(4) **Ro-ro passenger ship**: see 9.1.1.1(3) of Section 1 of this Chapter;
(5) **Ro-ro spaces**: see 9.1.1.2 of Section 1 of this Chapter;
(6) **Special category spaces**: see 9.1.1.3 of Section 1 of this Chapter.

9.4.2 Strength criteria of primary structures and securing and supporting devices

9.4.2.1 Scantlings of the primary members, securing and supporting devices of bow doors and inner doors are to be determined to withstand the design loads defined in 9.4.3 of this Section, using the following permissible stresses:

Permissible bending stress $[\sigma] = 120/K$ N/mm^2

Permissible shear stress $[\tau] = 80/K$ N/mm^2

Permissible equivalent stress $[\sigma_e] = \sqrt{\sigma^2 + 3\tau^2} = 150/K$ N/mm^2

where: K − material factor, but not to be taken less than 0.72 (unless a fatigue analysis is carried out).
9.4.2.2 The buckling strength of primary members is to be verified as being adequate.
9.4.2.3 For steel to steel bearings in securing and supporting devices, the nominal bearing pressure calculated by dividing the design force by the projected bearing area is not to exceed $0.8R_{eH}$, where R_{eH} is the yield stress of the bearing material. For other bearing materials, the permissible bearing pressure is to be determined according to the manufacturer's specification.
9.4.2.4 The arrangement of securing and supporting devices is to be such that threaded bolts do not carry support forces. The maximum tension in way of threads of bolts not carrying support forces is not to exceed $125/K$, in N/mm^2.

9.4.3 Design loads

9.4.3.1 Bow doors
(1) The design external pressure P_e, in kN/m^2, which is to be considered for the scantlings of primary members, securing and supporting devices of bow doors, is not to be less than that obtained from the following formula:

$$P_e = 2.75\lambda C_H (0.22 + 0.15\tan\alpha)(0.4V\sin\beta + 0.6\sqrt{L})^2 \quad \text{kN/m}^2$$

where: V — contractual ship's speed, in kn;
L — ship's length, in m, but need not be taken greater than 200 m;
λ — coefficient depending on the intended service of the ship:
$\lambda = 1$ for ships intended for unrestricted service;
C_H — coefficient, to be determined as follows:
$C_H = 0.0125L$ for $L < 80$ m;
$C_H = 1$ for $L \geq 80$ m;
α — flare angle at the point considered, defined as the angle between a vertical line and the

tangent to the side shell, measured in a vertical plane normal to the horizontal tangent to the outer shell of the door, with the considered point being on the bow door, $l/2$ aft of the stem line on the plane $h/2$ above the bottom of the door, see Figure 9.4.3.1(1);

l — length of the door on the plane $h/2$ above the bottom of the door, in m, see Figure 9.4.3.1(1);

β — entry angle at the point considered, defined as the angle between a longitudinal line parallel to the centreline and the tangent to the shell plating in a horizontal plane, with the considered point being the same as that of angle α, see Figure 9.4.3.1(1);

h — height, in m, of the door between the levels of the bottom of the door and the upper deck or between the bottom of the door and the top of the door, whichever is the lesser.

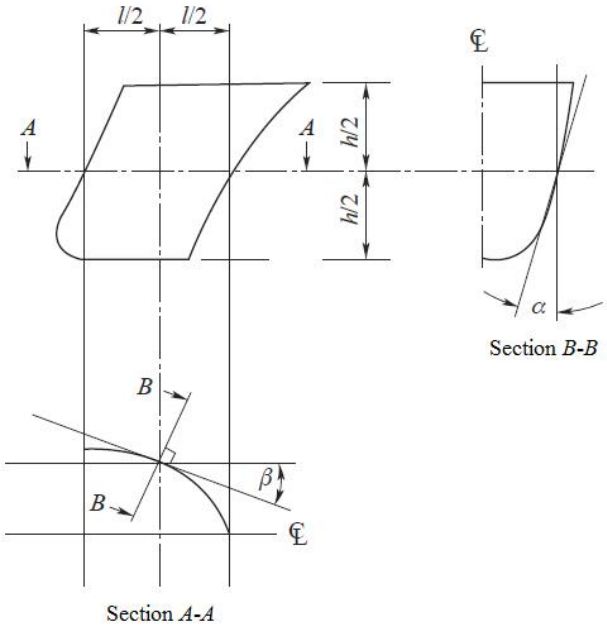

Figure 9.4.3.1(1)

(2) The design external forces, in kN, considered for the scantlings of securing and supporting devices of bow doors are to be determined by the following formulae:

$$F_x = P_e A_x \text{ kN}$$
$$F_y = P_e A_y \text{ kN}$$
$$F_z = P_e A_z \text{ kN}$$

where: A_x — area, in m^2, of the transverse vertical projection of the bow door between the levels of the bottom of the door and the top of the upper deck bulwark, or between the bottom of the door and the top of the door, including the bulwark, where it is part of the door, whichever is lesser. Where the flare angle of the bulwark is at least 15 degrees less than the flare angle of the adjacent shell plating, the height from the bottom of the door may be measured to the upper deck or to the top of the door, whichever is lesser. In determining the height from the bottom of the door to the upper deck or to the top of the door, the bulwark is to be excluded. See Figure 9.4.3.1(2);

A_y — area, in m^2, of the longitudinal vertical projection of the bow door between the levels of the bottom of the door and the top of the upper deck bulwark, or between the bottom of the door and the top of the door, including the bulwark, where it is part of the door, whichever is lesser. Where the flare angle of the bulwark is at least 15 degrees less than the flare angle of the adjacent shell plating, the height from the bottom of the door may be measured to the upper deck or to the top of the door, whichever is lesser. See Figure 9.4.3.1(2);

A_z — area, in m^2, of the horizontal projection of the bow door between the bottom of the door and the top of the upper deck bulwark, or between the bottom of the door and the top of the door, including the bulwark, where it is part of the door, whichever is the lesser. Where the flare angle of the bulwark is at least 15 degrees less than the flare angle of the adjacent shell plating, the height from the bottom of the door may be measured to the upper deck or to the top of the door, whichever is lesser. See Figure 9.4.3.1(2).

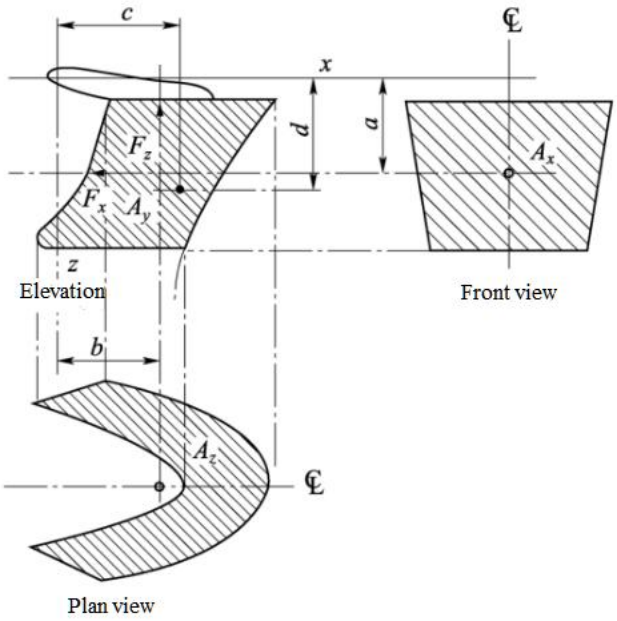

Figure 9.4.3.1(2)

For bow doors, including bulwark, of unusual form or proportions, e.g. ships with a rounded nose and large stem angles, the areas and angles used for determination of the design values of external forces are to be specially considered.

(3) For visor doors the closing moment M_y under external loads, in kN · m, is to be taken as:

$$M_y = F_x a + 10Wc - F_z b \quad \text{kN·m}$$

where: F_x, F_z — to be obtained in accordance with 9.4.3.1(2);

W — mass of the visor door, in t;

a — vertical distance, in m, from visor pivot to the centroid of the transverse vertical projected area of the visor door, as shown in Figure 9.4.3.1(2);

b — horizontal distance, in m, from visor pivot to the centroid of the horizontal projected area of the visor door, as shown in Figure 9.4.3.1(2);

c — horizontal distance, in m, from visor pivot to the centre of gravity of visor mass, as shown in Figure 9.4.3.1(2).

(4) Moreover, the lifting arms of a visor door and its supports are to be dimensioned for the static and dynamic forces applied during the lifting and lowering operations, and a minimum wind pressure of 1.5 kN/m^2 is to be taken into account.

9.4.3.2 Inner doors

(1) The design external pressure considered for the scantlings of primary members, securing and supporting devices and surrounding structure of inner doors is to be taken as the greater of p_e, external pressure and p_h, hydrostatic pressure:

$$p_e = 0.45L \quad \text{kN/m}^2$$
$$p_h = 10h \quad \text{kN/m}^2$$

where: L — the ship's length, in m, need not be taken as greater than 200 m;

h — the distance, in m, from the load point under consideration to the top of the cargo space.

(2) The design internal pressure p_i considered for the scantlings of securing devices of inner doors is not to be less than 25 kN/m^2.

9.4.4 Scantlings of bow doors

9.4.4.1 General requirements

(1) The strength of bow doors is to be commensurate with that of the surrounding structure.

(2) Bow doors are to be adequately stiffened and means are to be provided to prevent lateral or vertical movement of the doors when closed. For visor doors, adequate strength for the opening and closing operations is to be provided in the connections of the lifting arms to the door structure and to the ship structure.

9.4.4.2 Plating and stiffeners

(1) The thickness of the bow door plating is not to be less than that required for the side shell plating, using

bow door stiffener spacing, but in no case less than the minimum required thickness of fore end shell plating.
(2) The section modulus of horizontal or vertical stiffeners is not to be less than that required for end framing. Consideration is to be given, where necessary, to differences in fixity between ship's frames and bow door stiffeners.
(3) The stiffener webs are to have a net sectional area A not less than:

$$A = \frac{QK}{10} \quad \text{cm}^2$$

where: Q — shear force, in kN, in the stiffener, calculated by using uniformly distributed external pressure p_e as given in 9.4.3.1(1);
K — material factor.

9.4.4.3 Primary structure
(1) The bow door stiffeners are to be supported by primary members constituting the main stiffening elements of the door.
(2) The primary members of the bow door and the hull structure in way are to have sufficient stiffness to ensure the integrity of the boundary support of the door.
(3) Scantlings of the primary members are generally to be supported by direct strength calculations in association with the external pressure given in 9.4.3.1(1) of this Section and permissible stresses given in 9.4.2.1 of this Section. Normally, formulae for simple beam theory may be applied to determine the bending stress, with members being considered to have simply supported end connections.

9.4.5 Scantlings of inner doors

9.4.5.1 General requirements
(1) Scantlings of the primary members are generally to be supported by direct calculations in association with the external pressure given in 9.4.3.2(1) and permissible stresses given in 9.4.2.1 of this Section. Normally, formulae for simple beam theory may be applied.
(2) Where inner doors also serve as vehicle ramps, the scantlings are to comply with Section 6 of this Chapter.
(3) The distribution of the forces acting on the securing and supporting devices is generally to be supported by direct calculations taking into account the flexibility of the structure and the actual position and stiffness of the supports.

9.4.6 Securing and supporting of bow doors

9.4.6.1 General requirements
(1) Bow doors are to be fitted with adequate means of securing and supporting so as to be commensurate with the strength and stiffness of the surrounding structure. The hull supporting structure in way of the bow doors is to be suitable for the same design loads and design stresses as the securing and supporting devices. Where packing is required, the packing material is to be of a comparatively soft type, and the supporting forces are to be carried by the steel structure only. Other types of packing may be considered. Maximum design clearance between securing and supporting devices is generally not to exceed 3 mm.
A means is to be provided for mechanically fixing the door in the open position.
(2) Only the active supporting and securing devices having an effective stiffness in the relevant direction are to be included and considered to calculate the reaction forces acting on the devices. Small or flexible devices, such as cleats, intended to provide load compression of the packing material are generally not to be included in the calculations called for in 9.4.6.2(5) of this Section. The number of securing and supporting devices are generally to be the minimum practical whilst taking into account the requirements for redundant provision given in 9.4.6.2(6) and 9.4.6.2(7) of this Section and the available space for adequate support in the hull structure.
(3) For visor doors opening outwards, the pivot arrangement is generally to be such that the visor is self-closing under external loads, that is $M_y > 0$. Moreover, the closing moment M_y as given in 9.4.3.1(3) is not to be less than:

$$M_y = 10Wc + 0.1\sqrt{(a^2 + b^2)(F_x^2 + F_z^2)} \quad \text{kN} \cdot \text{m}$$

where: F_x, F_z — to be obtained in accordance with 9.4.3.1(2);
W — mass of the visor door, in t;
a — vertical distance, in m, from visor pivot to the centroid of the transverse vertical projected area of the visor door, as shown in Figure 9.4.3.1(2);
b — horizontal distance, in m, from visor pivot to the centroid of the horizontal projected area of the visor door, as shown in Figure 9.4.3.1(2);

c — horizontal distance, in m, from visor pivot to the centre of gravity of visor mass, as shown in Figure 9.4.3.1(2).

9.4.6.2 Scantlings

(1) Securing and supporting devices are to be adequately designed so that they can withstand the reaction forces within the permissible stresses given in 9.4.2.1.

(2) For visor doors, the reaction forces applied on the effective securing and supporting devices assuming the door as a rigid body are determined for the following combination of external loads acting simultaneously together with the self-weight of the door:

Case 1: F_x and F_z;

Case 2: $0.7F_y$ acting on each side separately together with $0.7F_x$ and $0.7F_z$.

(3) For side-opening doors, the reaction forces applied on the effective securing and supporting devices assuming the door as a rigid body are determined for the following combination of external loads acting simultaneously together with the self-weight of the door:

Case 1: F_x, F_y and F_z acting on both doors;

Case 2: $0.7F_x$ and $0.7F_z$ acting on both doors and $0.7F_y$ acting on each door separately.

F_x, F_y and F_z in (2) and (3) above are determined as indicated in 9.4.3.1(2) and applied at the centroid of projected areas.

(4) The support forces as determined according to 9.4.6.2(2) and (3) (Case 1) are generally to give rise to a zero moment about the transverse axis through the centroid of the area A_x (see Figure 9.4.3.1(2)). For visor doors, longitudinal reaction forces of pin and/or wedge supports at the door base contributing to this moment are not to be of the forward direction.

(5) The distribution of the reaction forces acting on the securing and supporting devices may require to be supported by direct calculations taking into account the flexibility of the hull structure and the actual position and stiffness of the supports.

(6) The arrangement of securing and supporting devices in way of these securing devices is to be designed with redundancy so that in the event of failure of any single securing or supporting device the remaining devices are capable of withstanding the reaction forces without exceeding by more than 20% the permissible stresses as given in 9.4.2.

(7) For visor doors, two securing devices are to be provided at the lower part of the door, each capable of providing the full reaction force required to prevent opening of the door within the permissible stresses given in 9.4.2.1 of this Section. The opening moment M_0 to be balanced by this reaction force is not to be taken less than:

$$M_0 = 10Wd + 5A_x a \quad \text{kN} \cdot \text{m}$$

where: A_x — to be obtained from 9.4.3.1(2) of this Section;

W — mass of the visor door, in t;

a — vertical distance, in m, from visor pivot to the centroid of the transverse vertical projected area of the visor door, as shown in Figure 9.4.3.1(2);

d — vertical distance, in m, from the hinge axis to the centre of gravity of the door, as shown in Figure 9.4.3.1(2).

(8) For visor doors, the securing and supporting devices excluding the hinges should be capable of resisting the vertical design force:

$F_z - 10W$, in kN, within the permissible stresses given in 9.4.2.1

where: F_z — to be obtained from 9.4.3.1(2);

W — mass of the visor door, in t.

(9) All load transmitting elements in the design load path, from door through securing and supporting devices into the ship structure, including welded connections, are to be to the same strength standard as required for the securing and supporting devices. These elements include pins, supporting brackets and back-up brackets.

(10) For side-opening doors, a thrust bearing has to be provided in way of girder ends at the closing of the two leaves to prevent one leaf to shift towards the other one under the effect of unsymmetrical pressure (see example of Figure 9.4.6.2). Each part of the thrust bearing has to be kept secured on the other part by means of securing devices. Any other arrangement serving the same purpose may be proposed.

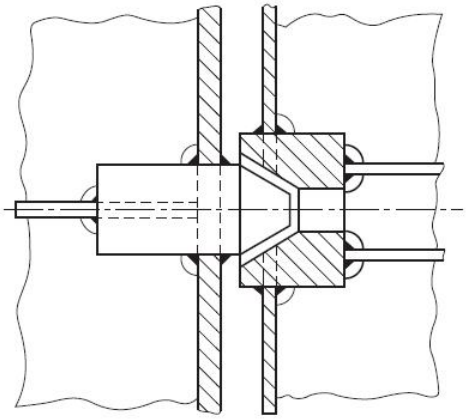

Figure 9.4.6.2

9.4.7 Securing and locking arrangements

9.4.7.1 Systems for operation

(1) Securing devices are to be simple to operate and easily accessible. Securing devices are to be equipped with mechanical locking arrangement (self-locking or separate arrangement), or to be of the gravity type. The opening and closing systems as well as securing and locking devices are to be interlocked in such a way that they can only operate in the proper sequence.

(2) Bow doors and inner doors giving access to vehicle decks are to be provided with an arrangement for remote control, from a position above the freeboard deck, of:

① the closing and opening of the doors; and

② associated securing and locking devices for every door.

Indication of the open/closed position of every door and every securing and locking device is to be provided at the remote control stations. The operating panels for operation of doors are to be inaccessible to unauthorized persons. A notice plate, giving instructions to the effect that all securing devices are to be closed and locked before leaving harbour, is to be placed at each operating panel and is to be supplemented by warning indicator lights.

(3) Where hydraulic securing devices are applied, the system is to be mechanically lockable in closed position. This means that, in the event of loss of the hydraulic fluid, the securing devices remain locked. The hydraulic system for securing and locking devices is to be isolated from other hydraulic circuits, when in closed position.

9.4.7.2 For indication/monitoring systems of doors, refer to the relevant requirements in Section 9, Chapter 2 of PART FOUR of the Rules.

9.4.8 Operating and maintenance manual

9.4.8.1 An Operating and Maintenance Manual for the bow door and inner door is to be provided on board and is to contain necessary information on:

(1) Main particulars and design drawings:

Special safety precautions;

Details of ship;

Equipment and design loading (for ramps);

Key plan of equipment (doors and ramps);

Manufacturer's recommended testing for equipment;

Description of equipment: bow doors, inner bow doors, bow ramp/doors, side doors, stern doors, central power pack, bridge panel, engine control room panel.

(2) Service conditions:

Limiting heel and trim of ship for loading/unloading;

Limiting heel and trim for door operations;

Doors/ramps operating instructions;

Doors/ramps emergency operating instructions.

(3) Maintenance:

Schedule and extent of maintenance;

Trouble shooting and acceptable clearances;

Manufacturer's maintenance procedures.

(4) Register of inspections, including inspection of locking, securing and supporting devices, repairs and

renewals.

It is to be ensured that the above mentioned items are contained in the OMM and that the maintenance part includes the necessary information with regard to inspections, troubleshooting and acceptance/rejection criteria①.

9.4.8.2 Documented operating procedures for closing and securing the bow door and inner door are to be kept on board and posted at appropriate place.

Section 5 SIDE SHELL AND STERN DOORS

9.5.1 General requirements for side and stern doors

9.5.1.1 This Section applies to the arrangement, strength and securing of side shell doors, abaft the collision bulkhead, and of stern doors leading to enclosed spaces.

9.5.1.2 Stern doors for passenger ships are to be situated above the freeboard deck. Stern doors for ro-ro cargo ships and side shell doors may be either below or above the freeboard deck.

9.5.1.3 Side shell doors and stern doors are to be so fitted as to ensure tightness and structural integrity commensurate with their location and the surrounding structure.

9.5.1.4 Where the sill of any side shell door is below the uppermost load line, the arrangement is to be specially considered, i.e. an inner door of equivalent strength and watertightness is to be fitted in the place. In that case a leakage detection device is to be provided in the compartment between the two doors. Further, drainage of this compartment to the bilges controlled by an easily accessible screw-down valve is to be arranged.

9.5.1.5 The doors are to preferably open outwards.

9.5.1.6 Definitions

(1) Securing device means a device used to keep the door closed by preventing it from rotating about its hinges or about pivoted attachments to the ship.

(2) Supporting device and locking device, ro-ro passenger ship, ro-ro space and special category space are as defined in 9.4.1.3, Section 4 of this Chapter.

9.5.2 Strength criteria of side shell doors and stern doors

9.5.2.1 Scantlings of the primary members, securing and supporting devices of side shell doors and stern doors are to be determined to withstand the design loads defined in 9.5.3, using the following permissible stresses:

Permissible bending stress $[\sigma] = 120/K$ N/mm^2

Permissible shear stress $[\tau] = 80/K$ N/mm^2

Permissible equivalent stress $[\sigma_e] = \sqrt{\sigma^2 + 3\tau^2} = 150/K$ N/mm^2

where: K — material factor, not to be taken less than 0.72 unless a direct strength analysis with regard to relevant modes of failures is carried out.

9.5.2.2 The buckling strength of primary members is to be verified as being adequate.

9.5.2.3 For steel to steel bearings in securing and supporting devices, the nominal bearing pressure calculated by dividing the design force by the projected bearing area is not to exceed $0.8R_{eH}$, where R_{eH} is the yield stress of the bearing material. For other bearing materials, the permissible bearing pressure is to be determined according to the manufacturer's specification.

9.5.2.4 The arrangement of securing and supporting devices is to be such that threaded bolts do not carry support forces. The maximum tension in way of threads of bolts not carrying support forces is not to exceed $125/K$, in N/mm^2, with K defined in 9.5.2.1 above.

9.5.3 Design loads of side shell doors and stern doors

9.5.3.1 The design forces, considered for the scantlings of primary members, securing and supporting devices of side shell doors and stern doors are not to be less than:

(1) Design forces for securing or supporting devices of doors opening inwards:

External force: $F_e = AP_e + F_p$ kN

Internal force: $F_i = F_o + 10W$ kN

(2) Design forces for securing or supporting devices of doors opening outwards:

---

① It is recommended that recorded inspections of the door supporting and securing devices be carried out by the ship's staff at monthly intervals or following incidents that could result in damage, including heavy weather or contact in the region of the shell doors. Any damages recorded during such inspections are to be reported to CCS.

External force: $F_e = AP_e$ kN

Internal force: $F_i = F_o + 10W + F_p$ kN

(3) Design forces for primary members:

External force: $F_e = AP_e$ kN

Internal force: $F_i = F_o + 10W$ kN

where: A — area, in m^2, of the door opening;

W — mass of door, in t;

F_p — total packing force in kN; packing line pressure is normally not to be taken less than 5 N/mm;

F_o — the greater of F_c and $5A$, in kN;

F_c — accidental force, in kN, due to loosening of cargo, etc., to be uniformly distributed over the area A and not to be taken less than 300 kN. For small doors such as bunker doors and pilot doors, the value of F_c may be appropriately reduced. However, the value of F_c may be taken as zero, provided an additional structure such as an inner ramp is fitted, which is capable of protecting the door from accidental forces due to loose cargoes, etc.;

P_e — external design pressure, in kN/m^2, determined at the centre of gravity of the door opening and not taken less than:

$$P_e = 10(T - Z_G) + 25 \quad kN/m^2, \text{ for } Z_G < d$$

$$P_e = 25 \quad kN/m^2, \text{ for } Z_G \geq d$$

Moreover, for stern doors of ships fitted with bow doors, P_e is not to be taken less than:

$$P_e = 0.6\lambda C_H(0.8 + 0.6\sqrt{L})^2 \quad kN/m^2$$

where: d — draught, in m, at the highest subdivision load line, in m;

Z_G — height of the centre of area of the door, in m, above the baseline;

λ — coefficient depending on the area where the ship is intended to be operated:

$\lambda = 1$ for ships intended for unrestricted service;

C_H — coefficient, to be determined as follows:

$C_H = 0.0125L$ for $L < 80$ m;

$C_H = 1$ for $L \geq 80$ m;

L — the ship's length, in m, need not be taken as greater than 200 m.

9.5.4 Scantlings of side shell doors and stern doors

9.5.4.1 The strength of side shell doors and stern doors is to be commensurate with that of the surrounding structure.

9.5.4.2 Side shell doors and stern doors are to be adequately stiffened and means are to be provided to prevent any lateral or vertical movement of the doors when closed. Adequate strength is to be provided in the connections of the lifting/manoeuvring arms and hinges to the door structure and to the ship's structure.

9.5.4.3 Where doors also serve as vehicle ramps, the design of the hinges should take into account the ship angle of trim and heel which may result in uneven loading on the hinges.

9.5.4.4 Shell door openings are to have well-rounded corners and adequate compensation is to be arranged with web frames at sides and stringers or equivalent above and below and they are to comply with the relevant requirements in 2.3.7 of Section 3, Chapter 2 of this PART.

9.5.4.5 The thickness of the door plating is not to be less than the required thickness for the side shell plating, using the door stiffener spacing, but in no case less than the minimum required thickness of shell plating. Where doors serve as vehicle ramps, the plating thickness is to comply with Section 6 of this Chapter.

9.5.4.6 The section modulus of horizontal or vertical stiffeners is not to be less than that required for side framing. Consideration is to be given, where necessary, to differences in fixity between ship's frames and door stiffeners. Where doors serve as vehicle ramps, the stiffener scantlings are to comply with Section 6 of this Chapter.

9.5.4.7 The secondary stiffeners are to be supported by primary members constituting the main stiffening elements of the door.

9.5.4.8 The primary members and the hull structure in way are to have sufficient stiffness to ensure structural integrity of the boundary of the door.

9.5.4.9 Scantlings of the primary members are generally to be supported by direct strength calculations in association with the design forces given in 9.5.3.1 of this Section and permissible stresses given in 9.5.2.1 of this Section. Normally, formulae for simple beam theory may be applied to determine the bending stresses. Members are to be considered to have simply supported end connections.

9.5.5 Securing and supporting of doors

9.5.5.1 Side shell doors and stern doors are to be fitted with adequate means of securing and supporting so as to be commensurate with the strength and stiffness of the surrounding structure. The hull supporting structure in way of the doors is to be suitable for the same design loads and design stresses as the securing and supporting devices.
Where packing is required, the packing material is to be of a comparatively soft type, and the supporting forces are to be carried by the steel structure only. Other types of packing may be considered.
Maximum design clearance between securing and supporting devices is generally not to exceed 3 mm.
A means is to be provided for mechanically fixing the door in the open position.
9.5.5.2 Only the active supporting and securing devices having an effective stiffness in the relevant direction are to be included and considered to calculate the reaction forces acting on the devices. Small and/or flexible devices such as cleats intended to provide local compression of the packing material are generally not to be included in the calculations called for in 9.5.5.4. The number of securing and supporting devices are generally to be the minimum practical whilst taking into account the requirement for redundant provision given in 9.5.5.5 and the available space for adequate support in the hull structure.
9.5.5.3 Securing and supporting devices are to be adequately designed so that they can withstand the reaction forces within the permissible stresses given in 9.5.2.1.
9.5.5.4 The distribution of the reaction forces acting on the securing devices and supporting devices may be supported by direct calculations taking into account the flexibility of the hull structure and the actual position of the supports.
9.5.5.5 The arrangement of securing devices and supporting devices in way of these securing devices is to be designed with redundancy so that in the event of failure of any single securing or supporting device the remaining devices are capable of withstanding the reaction forces without exceeding by more than 20% the permissible stresses as given in 9.5.2.1.
9.5.5.6 All load transmitting elements in the design load path, from the door through securing and supporting devices into the ship's structure, including welded connections, are to be to the same strength standard as required for the securing and supporting devices. These elements include pins, support brackets and back-up brackets.

9.5.6 Securing and locking arrangement and systems for operation

9.5.6.1 Securing devices are to be simple to operate and easily accessible.
Securing devices are to be equipped with mechanical locking arrangement (self-locking or separate arrangement), or are to be of the gravity type. The opening and closing systems as well as securing and locking devices are to be interlocked in such a way that they can only operate in the proper sequence.
9.5.6.2 Doors which are located partly or totally below the freeboard deck with a clear opening area greater than 6 m^2 are to be provided with an arrangement for remote control, from a position above the freeboard deck, of the closing and opening of the doors and associated securing and locking devices. For doors which are required to be equipped with a remote control arrangement, indication of the open/closed position of the door and the securing and locking device is to be provided at the remote control stations. The operating panels for operation of doors are to be inaccessible to unauthorized persons. A notice plate, giving instructions to the effect that all securing devices are to be closed and locked before leaving harbour, is to be placed at each operating panel and is to be supplemented by warning indicator lights.
9.5.6.3 Where hydraulic securing devices are applied, the system is to be mechanically lockable in closed position. This means that, in the event of loss of the hydraulic fluid, the securing devices remain locked. The hydraulic system for securing and locking devices is to be isolated from other hydraulic circuits, when in closed position.
9.5.6.4 For the indicating/monitoring systems of doors, see the relevant requirements in Section 9, Chapter 2 of PART FOUR of the Rules.

9.5.7 Operating and Maintenance Manual

9.5.7.1 An Operating and Maintenance Manual for the side shell and stern doors is to be provided on board and is to contain the necessary information on:
(1) Main particulars and design drawings
Special safety precautions;
Details of ship;
Equipment and design loading (for ramps);
Key plan of equipment (doors and ramps);
Manufacturer's recommended testing for equipment;
Description of equipment: bow doors, inner bow doors, bow ramp/doors, side doors, stern doors, central power pack, bridge panel, engine control room panel.

(2) Service conditions
Limiting heel and trim of ship for loading/unloading;
Limiting heel and trim for door operations;
Doors/ramps operating instructions;
Doors/ramps emergency operating instructions.
(3) Maintenance
Schedule and extent of maintenance;
Trouble shooting and acceptable clearances;
Manufacturer's maintenance procedures.
(4) Register of inspections and repairs
Including inspection of locking, securing and supporting devices, repairs and renewals.
It is to be ensured that the above mentioned items are contained in the OMM and that the maintenance part includes the necessary information with regard to inspections, troubleshooting and acceptance/rejection criteria①.
9.5.7.2 Documented operating procedures for closing and securing side shell and stern doors are to be kept on board and posted at the appropriate places.

Section 6 VEHICLE RAMPS

9.6.1 Structural strength of vehicle ramps
9.6.1.1 The relevant requirements of Section 21, Chapter 2 of this PART are to be complied with.

9.6.2 Framing of vehicle ramps
9.6.2.1 The strength is to be checked in accordance with the following requirements:
(1) the ramp is in a lowered position;
(2) the design vehicle load multiplied by coefficient 1.1 is the load acting on the ramp at its worst position and the mass of the ramp is also to be considered;
(3) allowable bending stress $[\sigma] = 141/K$, in N/mm^2, with K being the material factor; allowable deflection $[f] = l/200$ mm, with l being the distance between the supporting points of primary structures of vehicle ramps, in mm.

9.6.3 Connecting hinges of vehicle ramps
9.6.3.1 The following requirements are to be complied with:
(1) The diameter d of the axial pin is to comply with the following:

$$d \geq d_0$$

(2) The size of the central eye plate of hinges is to comply with the following:

$$\frac{F}{2b_0t_0} \leq [\tau], \quad b_0 \geq d_0$$

(3) The size of the eye plates on both sides of hinges is to comply with the following:

$$\frac{F}{4t_1t_2} \leq [\tau], \quad t_1 \geq d_0 / 2$$

where: d_0 — minimum required diameter of the axial pin, $d_0 = 0.92\sqrt{\frac{F}{[\tau]}}$ mm;

F— maximum force transmitted by the hinge, in N;
t_1, t_2, b_0, t_0, d — size of hinge parts, in mm, see Figure 9.6.3;
$[\tau]$ — allowable shear stress, to be taken as $[\tau] = 81.6/K$, in N/mm^2, K being the material factor.

① It is recommended that recorded inspections of the door supporting and securing devices be carried out by the ship's staff at monthly intervals or following incidents that could result in damage, including heavy weather or contact in the region of the shell doors or stern doors. Any damage recorded during such inspections is to be reported to CCS.

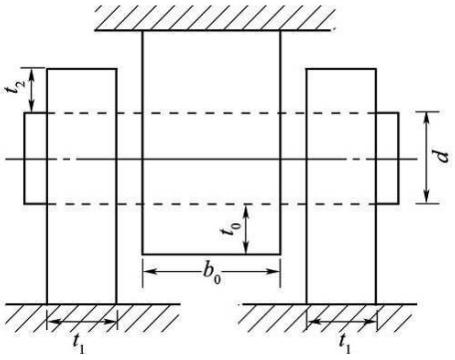

Figure 9.6.3

Section 7 DIRECT CALCULATIONS

9.7.1 General requirements

9.7.1.1 This Section specifies the methods to be used in direct calculations for the strength of transverses and girders of vehicle deck framing and for the transverse strength of hull structure.

9.7.2 Design loads and loading conditions

9.7.2.1 For the acceleration of ship motions, see the relevant requirements of Section 5, Chapter 1 of this PART

9.7.2.2 For direct strength calculation of vehicle deck structure, the deck load is to be calculated as follows:

Vehicle load $P_h = (g + 0.5a_v)M$ kN

Uniformly distributed load $p_{d_h} = (g + 0.5a_v)p$ kN/m^2

Deck weight load $p_{s_h} = (g + 0.5a_v)m_s$ kN/m^2

where: g — acceleration due to gravity, to be taken as 9.81 m/s^2;

a_v — vertical composite acceleration, in m/s^2, see 9.7.2.1 of this Section;

M — design vehicle mass, in t;

p — design uniformly distributed load of vehicle deck, in t/m^2, not to be less than 0.25 t/m^2;

m_s —deck weight, in t/m^2.

9.7.2.3 For direct calculation of transverse strength, the ship is assumed to heel to maximum heeling angle (if hull structures are not symmetrical to the longitudinal centerline, rolling towards portside and rolling towards starboard are to be considered separately) and the design load is to be calculated as follows:

(1) Vertical load and transverse load of vehicle deck are to be respectively calculated as follows:

Vertical load of vehicle $P_{r_v} = (g\cos\varphi_m + 0.5a_v)M$ kN

Transverse load of vehicle $P_{r_t} = (g\sin\varphi_m + 0.5a_t)M$ kN

Uniformly distributed vertical load $p_{d_r_v} = (g\cos\varphi_m + 0.5a_v)p$ kN/m^2

Uniformly distributed transverse load $p_{d_r_t} = (g\sin\varphi_m + 0.5a_t)p$ kN/m^2

Deck weight vertical load $p_{s_r_v} = (g\cos\varphi_m + 0.5a_v)m_s$ kN/m^2

Deck weight transverse load $p_{s_r_t} = (g\sin\varphi_m + 0.5a_t)m_s$ kN/m^2

where: g— acceleration due to gravity, to be taken as 9.81 m/s^2;

φ_m —maximum heeling angle, in rad, see 9.7.2.1 of this Section, to be taken not less than 0.35 rad;

a_v —vertical composite acceleration, in m/s^2, see 9.7.2.1 of this Section;

a_t —transverse composite acceleration, in m/s^2, see 9.7.2.1 of this Section;

M — design vehicle mass, in t;

p — design uniformly distributed load of vehicle deck, in t/m^2, not to be less than 0.25 t/m^2;

m_s — deck weight, in t/m^2.

(2) Vertical load and transverse load of superstructure deck and deckhouse deck are to be respectively calculated as follows:

Vertical load $p_{u_r_v} = (g\cos\varphi_m + 0.5a_v)m_0$ kN/m^2

Transverse load $p_{u_r_t} = (g\sin\varphi_m + 0.5a_t)m_0$ kN/m^2

where: g — acceleration due to gravity, to be taken as 9.81 m/s^2;

φ_m —maximum heeling angle, in rad, see 9.7.2.1 of this Section, to be taken not less than 0.35 rad;

a_v —vertical composite acceleration, in m/s^2, see 9.7.2.1 of this Section;

a_t —transverse composite acceleration, in m/s^2, see 9.7.2.1 of this Section;

m_0 — design load including deck weight, in t/m^2, not to be less than 0.25 t/m^2.

(3) The hydrostatic pressure p_{hs}, which is to be calculated in accordance with 1.5.3.2 of Section 5 of Chapter 1, is to be taken as the external sea pressure.

9.7.2.4 Calculation conditions are given in Tables 9.7.2.4.

Calculations conditions **Table 9.7.2.4**

Condition	Load area	Direction calculations of vehicle deck strength	Direction calculations of transverse strength
1	Vehicle deck	Vehicle load P_h Deck weight load p_{s_h}	Vehicle vertical load P_{r_v} Vehicle transverse load P_{r_t} Deck weight vertical load $p_{s_r_v}$ Deck weight transverse load $p_{s_r_t}$
	Superstructure and deckhouse	-	Vertical load $p_{u_r_v}$ Transverse load $p_{u_r_t}$
	External	-	Hydrostatic pressure p_{hs}
2	Vehicle deck	Uniformly distributed load P_{d_h} Deck weight load p_{s_h}	Uniformly distributed vertical load $p_{d_r_v}$ Uniformly distributed transverse load $p_{d_r_t}$ Deck weight vertical load $p_{s_r_v}$ Deck weight transverse load $p_{s_r_t}$
	Superstructure and deckhouse	-	Vertical load $p_{u_r_v}$ Transverse load $p_{u_r_t}$
	External	-	Hydrostatic pressure p_{hs}

9.7.3 Model and boundary conditions for strength calculation of vehicle deck structure

9.7.3.1 A 2- or 3-dimensional beam or plate/beam model may be used for direct strength calculations of vehicle deck structure, and the extent of the model is usually based on the following principles: Girders and transverses of the vehicle deck are to be taken as main objects of analysis, covering at least half the longitudinal length of the deck. Alternatively, a typical portion of the deck structure may be taken for modelling according to specific conditions of load distribution, deck structure and its supporting structures (e.g. pillars, bulkheads). Regardless of the length of the model, the whole tier of deck is to be considered for the selection of loads.

9.7.3.2 To minimize the effects of boundary constraints on the results of vehicle deck structure strength calculations, the boundary conditions are preferably to be applied at a suitable distance above and/or below the vehicle deck plane. For the fore and aft end planes of the model, the displacement in the longitudinal direction and the rotation about the coordinate axis perpendicular to the longitudinal direction are to be taken as zero.

9.7.4 Model and boundary conditions for transverse strength calculation

9.7.4.1 A 2- or 3-dimensional beam or plate/beam model may be used for direct transverse strength calculations, and the extent of the model is usually based on the following principles: Primary members of the deck and their supporting structures (e.g. pillars, bulkheads, side structures and transverse webs) are to be taken as main objects of analysis, covering at least in the vertical direction all tiers of decks and their supporting structures starting from baseline to the uppermost deck, in the transverse direction the entire breadth of the ship, and in the longitudinal direction at least the length of 5 strength frame rings or one design length of a vehicle amidships, whichever is the greater.

9.7.4.2 For the fore and aft end planes of the model, the displacement in the longitudinal direction and the rotation about the coordinate axis perpendicular to the longitudinal direction are to be taken as zero; For intersection lines AA', BB', CC', DD' of side ring frame or web frame and side shell plating, the displacement in vertical direction is to be taken as zero. For the intersection line $A'B'$ of inner bottom and portside shell plating, the displacement in transverse direction is to be taken as zero. Where inner bottom is not provided, the constraint of displacement in transverse direction may be applied to the intersection line EF of centre keelson and bottom plating (or similar position), see Figure 9.7.4.2.

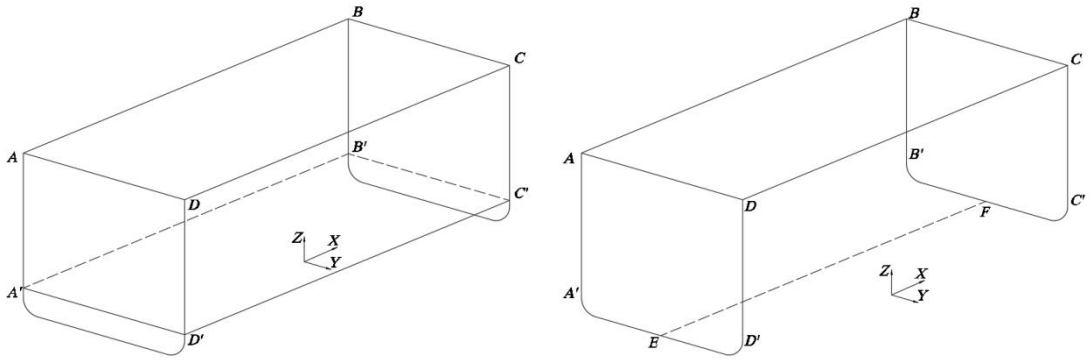

Figure 9.7.4.2

9.7.5 Permissible stresses

9.7.5.1 Permissible stresses for the 2- or 3-dimensional beam model:

Permissible bending stress $[\sigma]$ is to be:

$$[\sigma] = 165/K, \text{ in N/mm}^2$$

but $[\sigma]$ may be taken as $180/K$, in N/mm^2, for primary transverse members;

Permissible shear stress $[\tau]$ is to be:

$$[\tau] = 94/K, \text{ in N/mm}^2$$

where: K — material factor;

σ — bending stress, in N/mm^2;

τ — shear stress, in N/mm^2.

9.7.5.2 Permissible stress for plate/beam model

Permissible shear stress $[\tau]$ is to be:

$$[\tau] = 94/K, \text{ in N/mm}^2;$$

Permissible equivalent stress $[\sigma_e]$ is to be:

$$[\sigma_e] = \sqrt{\sigma_x^{\,2} + \sigma_y^2 - \sigma_x\sigma_y + 3\tau_{xy}^2} = 180/K, \quad \text{N/mm}^2$$

where: K — material factor;

σ_x — normal stress of the element in X direction under plane stress, in N/mm^2;

σ_y — normal stress of the element in Y direction under plane stress, in N/mm^2;

τ_{xy} — shear stress of the element in X direction under plane stress, in N/mm^2.

Section 8 EXTERNAL GLASS BALUSTRADES

9.8.1 General

9.8.1.1 The requirements of this Section apply solely to external glass balustrades. External glass balustrades are barriers constructed with glass that are used on exposed decks.

9.8.1.2 Glass balustrades, in lieu of bulwark or guard rails (see Section 19, Chapter 2 of this PART), may be accepted on exposed decks above position 2 specified in 1.1.2.22, Section 1, Chapter 1 of this PART, except on mooring deck and in way of lifeboats and life rafts and embarkation stations.

9.8.1.3 Glass is to be manufactured in accordance with a recognised National or International Standard.

9.8.1.4 The detailed arrangement, applicable loads and structural strength calculations are to be submitted to CCS.

9.8.2 Arrangement requirements

9.8.2.1 External glass balustrades are to be not less than 1 m in height.

9.8.2.2 In general, openings (e.g. the gaps between panels or the gap between the deck and the bottom of a panel) are not to be greater than 76 mm unless required for water freeing.

9.8.2.3 If a well is formed, the necessary drainage port is to be provided. Openings for water freeing are not to be greater than 230 mm.

9.8.3 Design pressure

9.8.3.1 For the lowest weather deck, the minimum design pressure P_w of glass balustrades is to be calculated as follows:

$$P_w = 9.81h, \quad \text{kN/m}^2$$

where: h——head in 2.17.2, Section 17, Chapter 2 of this PART.

9.8.3.2 For higher exposed decks, the minimum design pressure P_w of glass balustrades is to be calculated as follows:

(1) Below $1.7C$ m above the scantling draught, P_w=5kN/m^2, where C is the coefficient as specified in 2.2.3.1, Section 2, Chapter 2 of this PART;

(2) For other locations, P_w=2.5kN/m^2.

9.8.4 Minimum scantling requirements

9.8.4.1 External glass balustrades using monolithic glass are to comply with the following requirements:

(1) Minimum thickness of glass is not to be less than 6.0 mm;

(2) Top rail is required, with a minimum section modulus of 17 cm^3;

(3) Stanchions is to be fitted, not more than 1.5 m apart, with minimum section modulus of 20 cm^3.

9.8.4.2 External glass balustrades using laminated glass are to comply with the following requirements:

(1) Minimum thickness for each glass pane is not to be less than 4 mm;

(2) Top rail is required, with a minimum section modulus of 17 cm^3;

(3) Stanchions is to be fitted, not more than 1.5 m apart, with minimum section modulus of 20 cm^3.

9.8.4.3 The section modulus requirements in 9.8.4.1 and 9.8.4.2 above are based on steel. For other metallic materials, equivalent section modulus is to be calculated.

9.8.4.4 The glass panes are to be supported at minimum two opposite sides by metallic mounting frames. The glass panes can be fixed to the metal frame by mechanical means or adhesive. If the metal mounting frames are connected to the stanchion by bolts, there is to be no less than two force bolts on one side.

9.8.4.5 The overlap between the glass panes and metallic frames is not to be less than 10 mm or b/75 mm, whichever is greater, but not more than 20 mm, b is the breadth of the glass pane, in mm.

9.8.4.6 In public areas, laminated glass panes are required for external glass balustrades.

9.8.5 Glass thickness

9.8.5.1 For monolithic toughened glass, the thickness is to be less than the value obtained from the following formula:

$$t = b\sqrt{\beta P} / 200 \quad \text{mm}$$

where: b ——length of the shorter side of the glass, in mm;

P ——load for calculation, $P = 0.5Pw$, in kN/m^2;

P_w——design pressure, in kN/m^2, see 9.8.3 of this Section;

β ——coefficient, to be taken as follows:

1) glass with firm support on all sides:

$$\beta = 0.54A_R - 0.078A_R^2 - 0.17 \quad \text{for} \quad A_R \le 3.6$$

$$\beta = 0.7645 \quad \text{for} \quad A_R > 3.6$$

2) glass with firm support on two sides only:

$$\beta = 0.7645$$

where: A_R ——aspect ratio of rectangle window, to be taken as follows

$$A_R = a / b$$

a ——length of the longer side of the glass, in mm;

b ——length of the shorter side of the glass, in mm.

9.8.5.2 For laminated toughened glass, the equivalent thickness is to be less than the value obtained from 9.8.5.1. The equivalent thickness is calculated according to the following formula:

$$t_e = \sqrt{\sum_{i=1}^{n} t_i^2} \quad \text{mm}$$

where: n —number of glass layers;

t_i —thickness of the ith layer glass.

9.8.6 Balustrade stanchions

9.8.6.1 For balustrade stanchions below 1.7C m above the scantling draught, the section modulus W at the bottom is not to be less than:

$$W = 655 \frac{\mathrm{P\,Sl^2}}{\mathrm{R_{eH}}} \quad \text{cm}^3$$

where: S ——distance between stanchions, in m;

l ——height of the stanchion, in m;

P ——load for calculation, $P = Pw$, in kN/m^2;

P_w——design pressure, in kN/m^2, see 9.8.3 of this Section;

R_{eH}——yield stress of material, in N/mm^2.

9.8.6.2 For balustrade stanchions below 1.7C m above the scantling draught, the shear area A at the bottom is not to be less than:

$$A = 22.7 \frac{\mathrm{P\,Sl}}{\mathrm{R_{eH}}} \quad \text{cm}^2$$

where: S ——distance between stanchions, in m;

l ——height of the stanchion, in m;

P ——load for calculation, $P = Pw$, in kN/m^2;

R_{eH}——yield stress of material, in N/mm^2.

CHAPTER 10 TUGS

Section 1 GENERAL PROVISIONS

10.1.1 Application

10.1.1.1 The provisions of this Chapter apply to ships intended exclusively for towing.

10.1.1.2 Those not covered in this Chapter are to comply with the relevant requirements of Chapter 2 of this PART.

10.1.1.3 For the determination of scantlings of tugs, the draught d used is not to be less than 85% of the mounded depth.

10.1.1.4 For the calculation of rudder force, the design speed V of the ship is not to be taken as less than 10 kn.

10.1.2 Class notation

10.1.2.1 Tugs complying with the requirements of this Chapter are eligible to be assigned the class notation of Tug.

10.1.3 Plans and documents

10.1.3.1 In addition to those specified in Section 1, Chapter 2 of this PART, the following plan is to be submitted for approval:

(1) Supporting structure of towing equipment (appropriate strength calculations are submitted for information).

(2) Towing arrangement.

(3) Fender (structure) arrangement.

Section 2 HULL FRAMING

10.2.1 Web beam

10.2.1.1 A web beam is to be arranged throughout in way of the mid-portion of the long opening for the machinery space.

10.2.2 Side strengthening outside the fore peak

10.2.2.1 Where the side is framed transversely, the side framing outside the fore peak is to be strengthened in compliance with the requirements of 2.15.2, Chapter 2 of this PART, and the strengthened region is to be extended to 0.3L from the F.P. Within the region of strengthening, the section moduli of the main and 'tween deck frames are to be 20% greater than those required in Section 7, Chapter 2 of this PART.

Section 3 MACHINERY CASINGS

10.3.1 Machinery casings

10.3.1.1 The height of exposed machinery casings is not to be less than 900 mm. The stiffeners of the casings are to be spaced not more than 750 mm apart. The thickness of casing wall is to be increased by 20 % over that required in 2.17.9.3, Chapter 2 of this PART, while the section modulus of the stiffeners is to be increased by 50 % over that required in 2.17.9.3, Chapter 2 of this PART.

Section 4 BULWARKS AND FENDERS

10.4.1 Bulwarks

10.4.1.1 Tugs are to be provided with tumble-home bulwarks and the thickness t of bulwark plating is to comply with the following requirements:

t = 5 mm for $L \leq 30$ m;

t = 6 mm for $30 < L < 50$ m;

t = 7 mm for $L \geq 50$ m.

where: L — length of ship, in m.

10.4.1.2 The bulwarks are to be supported by stays with a flange or face plate. The stays are to be spaced not more than two frame spaces apart and are to be in line with the beams.

10.4.2 Fenders

10.4.2.1 Fenders are to be fitted along the deck line at side over the full length of the tug and are to have a thickness equal to that of side shell plating at 0.4L amidships. Stiffeners are to be arranged inside the fenders.

Section 5 TOWING ARRANGEMENTS AND SUPPORTING STRUCTURE

10.5.1 Towing hooks and towing winches

10.5.1.1 Towing hooks or the position of fixed towing guide point are normally to be situated at 5% to 10% of the ship's length abaft amidships, but in no case are they to be sited forward of the longitudinal centre of gravity of the tug in any anticipated condition of loading. In addition, they are to be located as low as practicable in order to minimize heeling moments arising in normal working conditions.

10.5.1.2 Towing winches and its members are to undertake the breaking loads of the towline selected by the tug and without permanent deformation. Towing hooks are to undertake the testing loads and without permanent deformation. The breaking loads of towlines and the testing loads of towing hooks may be determined according to CCS Guidelines for Towage at Sea.

10.5.2 Releasing arrangements

10.5.2.1 Towing hooks are to have reliable slip arrangements which facilitate towline releasing regardless of the direction of the towing line or the angle of heel and can avoid any inadvertent slipping.

10.5.2.2 The operating position of the slip arrangements is to be such as to ensure free visibility of the towing hook. It is recommended that the slip arrangements also be operable from the bridge.

10.5.3 Supporting structure

10.5.3.1 Pillars or pillar bulkheads are to be provided as far as possible under towing arrangements.

10.5.3.2 The design load for the supporting structure in way of towing arrangements is not to be less than the breaking loads of the towline selected by the tug.

10.5.3.3 The scantlings of primary members of the supporting structure are to be determined by direct calculations using the following allowable stresses:

Allowable shear stress: $[\tau] = 87/K$ N/mm²;

Allowable bending stress: $[\sigma] = 150/K$ N/mm²;

Allowable equivalent stress: $[\sigma_e] = \sqrt{\sigma^2 + 3\tau^2} = 213/K$ N/mm².

where: K — material factor.

Section 6 TOWING WINCH EMERGENCY RELEASE SYSTEMS

10.6.1 Scope and definitions

10.6.1.1 This Section defines minimum safety standards for winch emergency release systems provided on towing winches that are used on towing ships within close quarters, ports or terminals, including those ships normally not intended for towing operation in transverse direction.

10.6.1.2 This Section is not intended to cover towing winches on board ships used solely for long distance ocean towage, anchor handling or similar offshore activities.

10.6.1.3 This Section applies to ships contracted for construction on or after 1 January 2020.

10.6.1.4 The purpose of this section is to provide requirements to prevent the capsize of a tug when in the act of towage as a result of the towline force acting transversely to the tug (in beam direction) as a consequence of an unexpected event (could be loss of propulsion/steering or otherwise), whereby the resulting couple generated by offset and opposing transverse forces (towline force is opposed by thrust or hull resistance force) causes the tug to heel and, ultimately, to capsize, see Figure 10.6.1.4.

10.6.1.5 For the purposes of this Section, definitions are as follows:

(1) Emergency release system refers to the mechanism and associated control arrangements that are used to release the load on the towline in a controlled manner under both normal and black out conditions.
(2) Maximum design load is the maximum load that can be held by the winch as defined by the manufacturer (the manufacturer's rating).
(3) Fleet angle is the angle between the applied load (towline force) and the towline as it is wound onto the winch drum, see Figure 10.6.1.5.

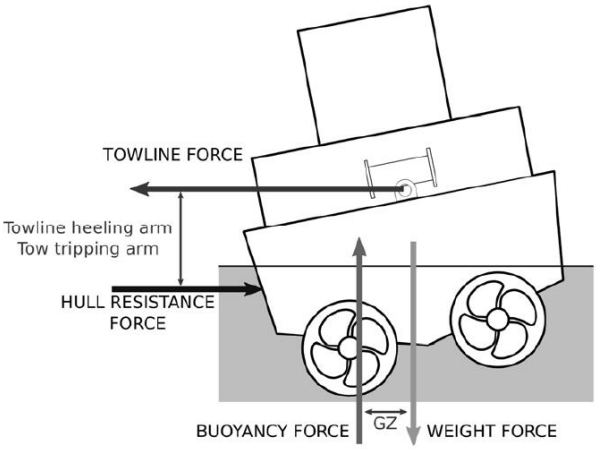

Figure 10.6.1.4 Forces during towing

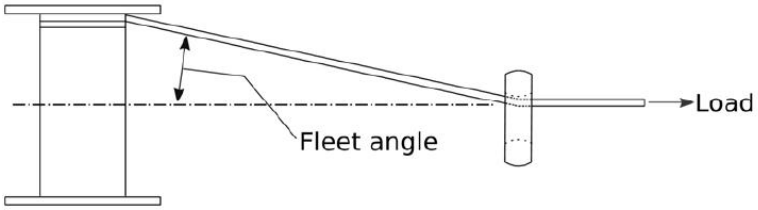

Figure 10.6.1.5 Towline fleet angle

10.6.2 General requirements

10.6.2.1 The in-board end of the towline is to be attached to the winch drum with a weak link or similar arrangement that is designed to release the towline at low load.
10.6.2.2 All towing winches are to be fitted with an emergency release system.

10.6.3 Performance requirements for emergency release system

10.6.3.1 The emergency release system is to operate across the full range of towline load, fleet angle and ship heel angle under all normal and reasonably foreseeable abnormal conditions (these may include, but are not limited to, the following: vessel electrical failure, variable towline load (for example due to heavy weather), etc.).
10.6.3.2 The emergency release system shall be capable of operating with towline loads up to at least 100 per cent of the maximum design load.
10.6.3.3 The emergency release system is to function as quickly as is reasonably practicable and within a maximum of three seconds after activation.
10.6.3.4 The emergency release system is to allow the winch drum to rotate and the towline to pay out in a controlled manner such that, when the emergency release system is activated, there is sufficient resistance to rotation to avoid uncontrolled unwinding of the towline from the drum. Spinning (free, uncontrolled rotation) of the winch drum is to be avoided, as this could cause the towline to get stuck and disable the release function of the winch.
10.6.3.5 Once the emergency release is activated, the towline load required to rotate the winch drum is to be no greater than:
(1) the lesser of five tonnes or five per cent of the maximum design load when two layers of towline are on the drum, or
(2) 15 per cent of the maximum design load where it is demonstrated that this resistance to rotation does not exceed 25 per cent of the force that will result in listing sufficient for the immersion of the lowest unprotected opening.

10.6.3.6 Emergency release of the towline is to be possible in the event of a blackout. For this purpose, where additional sources of energy are required, such sources are to comply with 10.6.3.7.
10.6.3.7 The alternative source of energy required by 10.6.3.6 of this Section is to be sufficient to achieve the most onerous of the following conditions (as applicable):
(1) sufficient for at least three attempts to release the towline (i.e. three activations of the emergency release system). Where the system provides energy for more than one winch it is to be sufficient for three activations of the most demanding winch connected to it.
(2) Where the winch design is such that the drum release mechanism requires continuous application of power (e.g. where the brake is applied by spring tension and released using hydraulic or pneumatic power) sufficient power is to be provided to operate the emergency release system (e.g. hold the brake open and allow release of the towline) in the event of a blackout for a minimum of five minutes. This may be reduced to the time required for the full length of the towline to feed off the winch drum at the load specified in 10.6.3.5 if this is less than five minutes.

10.6.4 Operational requirements for emergency release system
10.6.4.1 Emergency release operation must be possible from the bridge and from the winch control station on deck. The winch control station on deck is to be in a safe location. A position in close proximity to the winch is not regarded as safe location, unless it is documented that the position is at least protected against towline break or winch failure.
10.6.4.2 The emergency release control is to be located close to an emergency stop button for winch operation, if provided, and shall be clearly identifiable, clearly visible, easily accessible and positioned to allow safe operability.
10.6.4.3 The emergency release function is to take priority over any emergency stop function. Activation of the winch emergency stop from any location is not to inhibit operation of the emergency release system from any location.
10.6.4.4 Emergency release system control buttons are to require positive action to cancel, the positive action may be made at a different control position from the one where the emergency release was activated. It must always be possible to cancel the emergency release from the bridge regardless of the activation location and without manual intervention on the working deck.
10.6.4.5 Controls for emergency use are to be protected against accidental use.
10.6.4.6 Indications are to be provided on the bridge for all power supply and/or pressure levels related to the normal operation of the emergency release system. Alarms are to activate automatically if any level falls outside of the limits within which the emergency release system is fully operational.
10.6.4.7 Wherever practicable, control of the emergency release system is to be provided by a hard-wired system, fully independent of programmable electronic systems.
10.6.4.8 Computer based systems that operate or may affect the control of emergency release systems are to meet the requirements for Category III systems of Section 6, Chapter 2 of PART SEVEN of the Rules.
10.6.4.9 Components critical for the safe operation of the emergency release system are to be identified by the manufacturer.

10.6.5 Test requirements for emergency release system
10.6.5.1 General requirements
(1) All testing defined within this Section is to be witnessed by a CCS surveyor.
(2) For each emergency release system or type thereof, the performance requirements of 10.6.3 of this Section are to be verified either at the manufacturer's works or as part of the commissioning of the towing winch when it is installed on board. Where verification solely through testing is impracticable (e.g. due to health and safety), testing may be combined with inspection, analysis or demonstration in agreement with CCS.
(3) The performance capabilities, as well as instructions for operation of the emergency release system are to be documented by the manufacturer and made available on board the ship on which the winch has been installed.
(4) Instructions for surveys of the emergency release system are to be documented by the manufacturer, when agreed, and made available on board the ship on which the winch has been installed.
(5) Where necessary for conducting the annual and special surveys of the winch, adequately sized strong points are to be provided on deck.
10.6.5.2 Installation trials
(1) The full functionality of the emergency release system is to be tested as part of the shipboard commissioning trials to the satisfaction of the surveyor. Testing may be conducted either during a bollard pull test or by applying the towline load against a strong point on the deck of the tug that is certified to the

appropriate load.
(2) Where the performance of the winch in accordance with 10.6.3 of this Section has previously been verified, the load applied for the installation trials is to be at least the lesser of 30% of the maximum design load or 80% of vessel bollard pull.

CHAPTER 11 OFFSHORE SUPPLY SHIPS

Section 1 GENERAL PROVISIONS

11.1.1 Application

11.1.1.1 This Chapter applies to offshore supply ships specially designed and constructed for the carriage of specialized stores and cargoes to mobile or fixed offshore installations, and also to offshore tug/supply ships and offshore anchoring handling/tug/supply ships.

11.1.1.2 Those not covered in this Chapter are to comply with the relevant requirements of Chapter 2 of this PART.

11.1.1.3 This Chapter applies to supply ships having the accommodation and bridge erections in the forward part of the vessel and an exposed deck in the after part for the handling of cargo at sea.

11.1.1.4 In addition to the requirements of this Chapter, tug/supply ships are to comply with the relevant requirements as specified in Section 5, Chapter 10 of this PART. A tug/supply ship, when engaged in towing operations, is in general not to carry deck cargo.

11.1.2 Class notations

11.1.2.1 Ships complying with the requirements of this Chapter are eligible to be assigned one of the following class notations:

(1) Offshore Supply Ship for offshore supply ships; or

(2) Offshore Tug/Supply Ship for offshore tug/supply ships.

11.1.3 Plans and documents

11.1.3.1 In addition to the plans and documents required in Section 1, Chapter 2 of this PART, plans covering the following items are to be submitted for approval:

(1) Independent cargo tanks and their foundations and securing arrangements;

(2) Drawing of the deck(s) showing the details of loads, the points where they apply and lashing arrangement;

(3) Towing arrangement;

(4) Supports and foundations for towing winches, stern towing bollards and for stern rollers of anchor handling/supply ships (appropriate strength calculations are submitted for information);

(5) Movable decks, including the stowing arrangements for portable components;

(6) Freeing arrangement;

(7) Fender arrangement (structure).

Section 2 CARGO CONTAINMENT AND OTHER FITTINGS

11.2.1 Cargo containment

11.2.1.1 Means are to be provided to enable deck cargoes to be adequately secured and protected. In general, suitable inner bulwarks, rails, bins or storage racks of substantial construction are to be provided and properly secured to adequately strengthened parts of the hull structure.

11.2.1.2 Properly designed locking equipment or efficient means for lashing the deck cargoes are to be fitted where appropriate.

11.2.1.3 Small hatches (including escape hatches), control valves, ventilators, air pipes, etc., are to be situated clear of the cargo containment areas and fitted in protected positions.

11.2.2 Doors and accesses

11.2.2.1 If possible, the accesses to machinery spaces are to be arranged in forecastle. Any accesses to machinery spaces from weather cargo decks are to be provided with two weathertight closing appliances. The accesses to spaces below the weather cargo decks are to be preferably from a position on or above the superstructure deck as far as possible.

11.2.2.2 Doors leading directly to and hatches on the open cargo deck are to be kept closed during navigation. These doors are to be clearly marked to indicate that they are to be kept closed except for access.

11.2.3 Side scuttles, windows and skylights

11.2.3.1 Side scuttles, windows and skylights are to comply with the relevant requirements of Section 12, Chapter 1 of this PART.

11.2.3.2 Windows are only allowed to be fitted in the following locations and side scuttles are to be fitted in other positions.

(1) Second tier and higher above the freeboard deck:

① in the aft end bulkheads of deckhouses and superstructures;

② in the sides of deckhouses and superstructures which are not part of the shell plating;

(2) Third tier and higher above the freeboard deck:

① in the forward facing bulkheads of deckhouse and superstructures, except that in the first tier of the front bulkhead above the weather deck, only side scuttles will be accepted.

11.2.3.3 Permanently attached deadlights are to be provided as follows:

(1) Side scuttles:

① in the side shell plating;

② in the forward facing bulkheads of superstructures and deckhouses;

③ in the sides of deckhouses and superstructures up to and including the third tier above the freeboard deck;

④ in the after end bulkheads of superstructures, deckhouses, casings and companionways in the first and second tiers above the freeboard deck.

(2) Windows:

① in the sides of deckhouses and superstructures in the second and third tiers above the freeboard deck;

② in the after end bulkheads of superstructures, deckhouses, casings and companionways in the second tier above the freeboard deck.

11.2.3.4 On windows in the second tier and higher above the freeboard deck, hinged storm covers may be fitted in lieu of deadlights, provided there is safe access for closing.

11.2.3.5 Windows in the wheelhouse front are to have deadlights or storm covers. For storm covers, an arrangement for easy and safe access is to be provided, (e.g. gangway with railing). However, for practical purposes, the deadlights or storm covers may be portable if stowed adjacent to the window for quick fitting. At least two of the deadlights or storm covers are to have the means of providing a clear view.

11.2.3.6 Deadlights for side scuttles, and for windows not mentioned in 11.2.3.4 and 11.2.3.5, are to be internally hinged.

11.2.3.7 The thickness of toughened glass for windows is not to be less than the value calculated by the following formula, and the minimum is not to be less than 10 mm.

$$t = b\sqrt{\varphi\beta\eta h} \qquad \text{mm}$$

where:

φ — coefficient, taken as 2 for fronts, 1.2 for sides and aft ends;

η — coefficient, taken as 223 for fronts and sides on the forth tier or above, 125 for aft ends on the forth tier or above, 500 for other cases;

h — design head of window, calculated according to 2.17.2, Chapter 2 of this PART;

β — coefficient, to be calculated by the following:

$$\beta = 0.54A_R - 0.078A_R^2 - 0.17 \quad \text{for} \quad A_R \le 3.6$$

$$\beta = 0.7645, \quad \text{for} \quad A_R > 3.6$$

where: A_R —aspect ratio factor of window, calculated by the following equation:

$$A_R = a/b$$

a — length of long edge of window, in m;

b — length of short edge of window, in m.

11.2.3.8 Skylights, where fitted, are to be of substantial construction. The height of coamings of skylights is not to be less than 600 mm when situated on open freeboard decks, and raised quarter decks and open superstructure decks forward of 1/4L from F.P., and 450 mm when situated on open superstructure decks abaft of 1/4L from F.P. The thickness of glass in skylights is to be equal to that required for side scuttles or windows at the same position. Skylights are to be provided with strong storm covers.

11.2.3.9 For laminated toughened glass, the equivalent thickness is not to be less than that calculated according to 11.2.3.7. The equivalent thickness is to be calculated by the following formula and the thickness of single layer of glass is not to be less than 4 mm.

$$t_e = \sqrt{\sum_{i=1}^{n} t_i^2}$$

where: n — the number of layer of glass;
t_i — the thickness of the i[th] layer of glass.

11.2.4 Air pipes, ventilators and freeing ports

11.2.4.1 Air pipes situated on the exposed cargo and forecastle decks are to be provided with automatic closing devices.

11.2.4.2 Machinery space ventilators are to be arranged above the superstructure deck, or above an equivalent level if no superstructure deck is fitted.

11.2.4.3 The area of the freeing ports in the side bulwarks on the cargo deck is to be suitably increased above that required in 1.12.6.2, Chapter 1 of this PART. The disposition of the freeing ports is to be carefully considered to ensure the most effective drainage of water trapped in deck cargoes or in recesses in the after end bulkhead of the forecastle.

In ships operating in areas where icing is likely to occur, no shutters are to be fitted in the freeing ports.

11.2.4.4 Engine exhaust outlets are to be located as high as practicable above the deck and are to be fitted with spark arresters.

Section 3 SHELL AND DECK PLATING

11.3.1 Shell plating

11.3.1.1 The thickness of side shell is to be in accordance with the relevant requirements of Section 3, Chapter 2 of this PART, but is in no case to be less than 9 mm.

11.3.1.2 The side shell in way of the stern rollers immediately adjacent to high duty mooring bollards and in other high load areas of anchor handling/supply ships is to be suitably reinforced.

11.3.2 Decks

11.3.2.1 The minimum thickness t of deck plating is not to be less than that obtained from the following formula:

$$t = 0.025L + 7 \quad \text{mm}$$

where: L — length of ship, in m.

In the deck cargo area, the thickness t of deck plating is, in addition, in no case to be less than that obtained from the following formula:

$$t = 4.8s\sqrt{hK} + 2.5 \quad \text{mm}$$

where: s — spacing of beams or longitudinals, in m;
h — design head, in m, to be determined from $h = 0.14p$ (p being the load of deck, in kPa), but not to be less than 3.5 m;
K — material factor.

11.3.2.2 The deck plating near the stern and that subject to concentrated loads are to be suitably increased in thickness.

Section 4 HULL ENVELOPE FRAMING

11.4.1 Deck framing

11.4.1.1 The scantlings of cargo decks are to be suitable for the specified loadings, but in no case is a head less than 3.5 m to be used.

11.4.1.2 Additional local increases in scantlings is to be required where specific cargoes are likely to induce concentrated loads.

11.4.2 Side framing

11.4.2.1 Efficient fenders are to be fitted to the ship's side above the waterline, and are to have a thickness equal to that of side shell. Stiffeners are to be arranged inside the fenders. If fenders are not provided, the thickness of the shell plating at least 600 mm below the deck is to be increased by 5 mm.

11.4.2.2 The section moduli of the main and 'tween deck frames are to be 25% greater than those required in Section 7 of Chapter 2 of this PART. Frames are not to be scalloped.

11.4.3 Bottom framing

11.4.3.1 The flat bottom in way of stern is to be suitably strengthened.

Section 5 SUPERSTRUCTURES AND DECKHOUSES

11.5.1 Scantlings

11.5.1.1 The section modulus of the frames in superstructures is to be 25% greater than that required in Section 7, Chapter 2 of this PART. The scantlings of the end bulkheads of superstructures are not to be less than those as specified in Table 11.5.1.2 of this Section.

11.5.1.2 The scantlings of deckhouses situated on the forecastle deck and above are to comply with the requirements of Table 11.5.1.2.

Plate thickness, Stiffener Modulus and Depth of Deckhouses Table 11.5.1.2

Position	Thickness t of plating (mm)	Section modulus W of stiffeners (cm^3)	Depth of stiffeners (mm)
Fronts	The greater of 12s or 8.0	34sl^2	Not less than 100
Sides	The greater of 10s or 6.5	27sl^2	Not less than 75
Aft ends	The greater of 8s or 6.5	27sl^2	Not less than 65

Note: s and l are respectively spacing and span of stiffeners, in m.

11.5.2 End connection

11.5.2.1 Both ends of the stiffeners in superstructures and deckhouses are to be bracketed or connected by other effective means on all tiers.

CHAPTER 12 BARGES

Section 1 GENERAL PROVISIONS

12.1.1 Application

12.1.1.1 The barges defined in this Chapter are non-self-propelled ships pushed or towed by other ships and divided into the following types:

(1) Barges carrying general dry cargo in cargo holds;

(2) Barges carrying cargo oil in cargo tanks;

(3) Shipborne barges carrying general dry cargo in cargo holds and carried on board a barge carrier;

(4) Specially designed pontoons for the carriage of cargo on deck;

(5) Barges dedicated to transporting marine engineering jacket structure and landing jacket into water by the stern for launching of jacket;

(6) Barges carrying chemicals in cargo tanks;

(7) Barges carrying liquefied gas in cargo tanks.

12.1.1.2 Where not covered by this Chapter, barges carrying cargo oil in bulk in cargo tanks are to comply with the relevant requirements of Chapter 5 or 6 of this PART according to its structural configuration; barges carrying chemicals in cargo tanks are to comply with the relevant requirements of Chapter A4, PART TWO of CCS Rules for Construction and Equipment of Ships Carrying Dangerous Chemicals in Bulk; barges carrying liquefied gas in cargo tanks are to comply with the relevant requirements of Appendices 1 and 2, PART TWO of CCS Rules for Construction and Equipment of Ships Carrying Liquefied Gas in Bulk and other barges are to comply with the relevant requirements of Chapter 2 of this PART.

12.1.1.3 For pontoons regarded as one of offshore floating facilities, the structure may be in accordance with the requirements of this Chapter for pontoon barges.

12.1.2 Class notations

12.1.2.1 Barges complying with the requirements of this Chapter are eligible to be assigned one of the following class notations:

(1) Barges: the notation Barge is to be assigned to the barges as defined in 12.1.1.1(1);

(2) Oil barges: the notation Oil Barge is to be assigned to the barges as defined in 12.1.1.1(2);

(3) Shipborne barges: the notation Shipborne Barge is to be assigned to the barges as defined in 12.1.1.1(3);

(4) Pontoon barges: the notation Pontoon Barge is to be assigned to the barges as defined in 12.1.1.1(4);

(5) Launch Barge: the notation Launch Barge is to be assigned to the barges as defined in 12.1.1.1(5);

(6) Chemical Barge: the notation Chemical Barge is to be assigned to the barges as defined in 12.1.1.1(6);

(7) Gas Barge: the notation Gas Barge is to be assigned to the barges as defined in 12.1.1.1(7).

12.1.3 Plans and documents

12.1.3.1 In addition to the plans and documents required in Section 1, Chapter 2 of this PART, plans and documents covering the following are to be submitted for approval:

(1) Details of structure and fittings to which deck cargo securing lashings, etc. are attached;

(2) Details of bollards and their supporting structure;

(3) Where pusher tugs or integral tug/barge systems are proposed, full details and data of the attachment and support arrangements;

(4) Longitudinal strength (appropriate strength calculations are submitted for information) and lifting arrangements for shipborne barges.

12.1.4 Structural configuration

12.1.4.1 For barges with large deck openings, deck and bottom are in general to be longitudinally framed.

12.1.4.2 Barges are to be fitted with a collision bulkhead extending intact to the strength/weather deck and, in general, this is to be located in accordance with Table 12.1.4.2. Greater distance between the collision bulkhead and the forward perpendicular may be accepted if assessed by damage stability calculation.

Table 12.1.4.2

Length L of ship (m)	Distance between collision bulkhead and forward perpendicular (m)	
	Minimum	Maximum
≤ 150	0.05L	0.05L + 4.5
> 150	0.05L or 10, whichever is the lesser	0.08L

12.1.4.3 Where the ends of the barge are identical both in structural arrangement and in shape so that its fore and after ends are not distinguishable, collision bulkheads are to be fitted at both ends.

12.1.4.4 Pusher barges are in general to be fitted with a collision bulkhead at the aft end.

12.1.4.5 The total number of watertight bulkheads is in general not to be less than required in Table 12.1.4.5. For ships of over 190 m in length, this is to be determined by direct calculation. Attention is to be paid to reasonable and even arrangement of transverse watertight bulkheads.

Total Number of Transverse Watertight Bulkheads **Table 12.1.4.5**

Length L (m)	$L \leq 60$	$60 < L \leq 85$	$85 < L \leq 105$	$105 < L \leq 145$	$145 < L \leq 165$	$165 < L \leq 190$
Total number of watertight bulkheads	3	4	5	6	7	8

12.1.4.6 Pontoon barges are in general to be fitted with longitudinal bulkheads extending fore and aft in accordance with Table 12.1.4.6, the scantlings of which are to be calculated as required for watertight longitudinal bulkheads. Attention is to be paid to reasonable arrangement of longitudinal bulkheads. For pontoon barges with B/D greater than 6, this is to be determined by direct calculation.

Total Number of Longitudinal Bulkheads **Table 12.1.4.6**

B/D	$B/D \leq 2.5$	$2.5 < B/D \leq 3$	$3 < B/D \leq 4$	$4 < B/D \leq 5$	$5 < B/D \leq 6$
Total number of longitudinal bulkheads	0	1	2	3①	3

Note: ① Centre longitudinal bulkheads may be replaced by longitudinal trusses.

12.1.4.7 For pontoon barges with B/D equal to or greater than 3, the transverse strength is to be checked by direct calculation (see Appendix 1 of this Chapter).

Section 2 LONGITUDINAL STRENGTH

12.2.1 General requirements

12.2.1.1 The longitudinal strength of barges is to comply with the relevant requirements of Section 2, Chapter 2 of this PART, with the exception of the requirements for loading instruments.

12.2.1.2 For shipborne barges intended to be lifted on board by crane, longitudinal strength calculations for a condition "fully loaded barge suspended by crane" are to be made with the following permissible stresses:

Permissible bending stress $[\sigma] = 150/K$ N/mm²

Permissible shear stress $[\tau] = 100/K$ N/mm²

where: K — material factor.

12.2.1.3 For barges having large deck openings, torsional strength is to be checked in accordance with Chapter 7 of this PART.

12.2.1.4 Where the transverse watertight bulkheads and longitudinal bulkheads of pontoon barges are fitted in compliance with the requirements for structural arrangement in Section 1 of this Chapter, their proportions may exceed those specified in 2.2.1.2 of Section 2, Chapter 2 of this PART when the requirements for longitudinal strength in Section 2, Chapter 2 of this PART are applied, provided that the following condition is met:

$$L/B > 3$$

$$B/D \leq 6.0$$

12.2.1.5 For pontoon barges not meeting the condition in 12.2.1.4 above, this is generally to be determined by direct calculation. See 2.2.9 of Chapter 2 for direct calculation of wave loads.

Section 3 SHELL AND DECK PLATING

12.3.1 General requirements

12.3.1.1 In addition to the requirements of this Section, the shell and deck plating of barges carrying cargo oil in cargo tanks are to comply with the relevant requirements of Chapter 6 of this PART and those of other barges are to comply with the relevant requirements of Chapter 2 of this PART.

12.3.2 Shell plating Decks

12.3.2.1 On barges with two chines each side, the thickness of bilge plating is to be calculated from the bottom plating formulae. On hard chine barges, flanged chines will not, in general, be approved, but where a chine is formed by knuckling the shell plating, the radius of curvature, measured on the inside of the plate, is not to be less than 10 times the plate thickness. Where a solid round chine bar is fitted, the bar diameter is not to be less than 3 times the thickness of the thickest abutting plate. Where welded chines are used, the welding is to be built up as necessary to ensure that the shell plating thickness is maintained across the weld.

12.3.2.2 For barges of less than 100 m in length and without dead rise, the thickness of plate keel is to be calculated from the bottom plating formulae.

12.3.3 Decks

12.3.3.1 For barges with large deck openings, the half sectional area a of the strength deck within $0.4L$ amidships is not to be less than that obtained from the following formula:

$$a = \frac{1}{4.3} B(L + 30) \quad \text{cm}^2$$

where: L — length of ship, in m;
B — breadth of ship, in m.

The half sectional area of deck means the sum of sectional areas of the continuous longitudinal members outside the line of openings and on one side of the longitudinal centreline, such as deck plating, deck longitudinals and deck girders.

12.3.3.2 For pontoons, the thickness of deck plating in the deck cargo area is, in addition, not to be less than that obtained from the following formula:

$$t = 4.5s\sqrt{hK} \quad \text{mm, but not less than 6 mm}$$

where: s — spacing of beams or longitudinals, in m;
h — design head, in m, to be taken as $0.14p + 0.3$, p being the design load, in kPa;
K — material factor.

12.3.3.3 Where vehicles are to be carried on deck, the deck plating is also to comply with the relevant requirements of Section 21, Chapter 2 of this PART.

Section 4 HULL ENVELOPE FRAMING

12.4.1 General requirements

12.4.1.1 The hull envelope framing of barges carrying dry cargo in cargo holds are to comply with the relevant requirements of Chapter 2 of this PART. The hull envelope framing of barges carrying cargo oil in cargo tanks are to comply with the relevant requirements of Chapter 6 of this PART. The hull envelope framing of pontoon barges are to comply with the relevant requirements of this Section.

12.4.1.2 In way of deck and bottom primary transverse members, a web frame is to be fitted so that the bottom, side and deck transverses are connected into a transverse ring system to ensure sufficient transverse strength.

12.4.1.3 Pontoon barges are in general longitudinally framed. If they are framed transversely, transverse ring systems or transverse trusses are to be suitably fitted to ensure sufficient transverse strength.

12.4.1.4 Figure 12.4.1.4 shows the longitudinally framed structure of pontoon barges.

12.4.1.5 Figure 12.4.1.5 shows the transversely framed structure of pontoon barges.

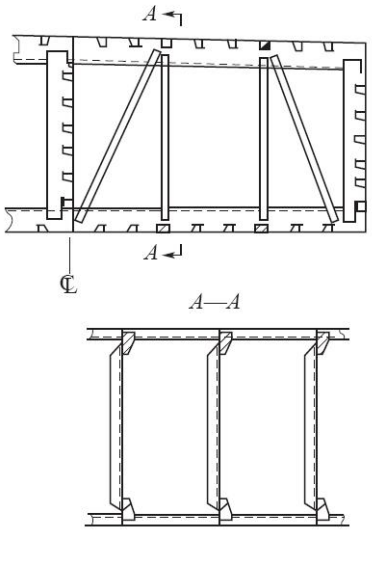

Figure 12.4.1.4

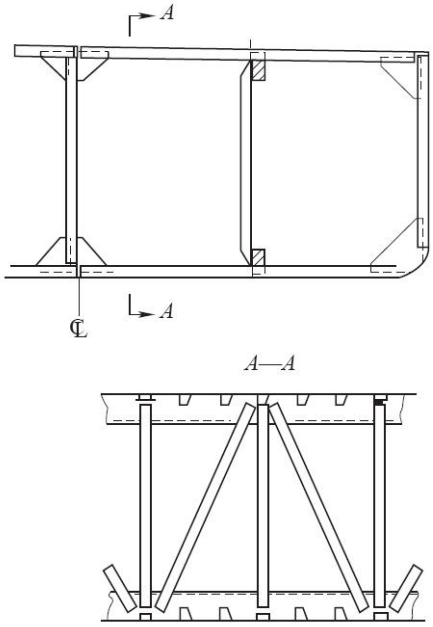

Figure 12.4.1.5

12.4.2 Bottom framing of pontoons

12.4.2.1 Where transversely framed, bottom frames are to be fitted at every frame, and their section modulus W is not to be less than that obtained from the following formula:

$$W = 9.5sDl^2K \quad \text{cm}^3$$

where: s — spacing of bottom frames, in m;

D — moulded depth, in m;

l — span of bottom frames, in m; supporting structures of bottom frames are to be ship side, longitudinal bulkheads or bottom stringers;

K — material factor.

12.4.2.2 Where longitudinally framed, the section modulus W of bottom longitudinals is not to be less than that obtained from the following formula:

$$W = CsDl^2K \quad \text{cm}^3$$

where: s — spacing of longitudinals, in m;

D — moulded depth, in m;

l — span of longitudinal, in m; supporting structures of bottom longitudinals are to be transverse bulkheads or bottom webs;

C — coefficient, taken as:

$C = 12$, for rake-ended bow of pontoon barges;

$C = 10.5$, for others;

K — material factor.

12.4.2.3 The section modulus W of bottom stringers (including bottom chords of longitudinal trusses) is not to be less than that obtained from the following formula:

$$W = 9.5SDl^2K \quad \text{cm}^3$$

where: S — average width of areas supported by bottom stringers, in m;

D — moulded depth, in m;

l — span of bottom stringers, in m; supporting structures of bottom stringers are to be transverse bulkheads, truss pillars;

K — material factor.

12.4.2.4 The section modulus W of bottom webs (including bottom chords of transverse trusses) is not to be less than that obtained from the following formula:

$$W = CSDl^2K \quad \text{cm}^3$$

where: S — average width of areas supported by bottom webs, in m;

D — moulded depth, in m;

l — span of bottom web, in m; supporting structures of bottom webs are to be ship side, longitudinal bulkheads or truss pillars;

C — coefficient, taken as:

$C = 11$, for rake-ended bow of pontoon barges;

C = 9.5, for others;

K — material factor.

12.4.2.5 Primary bottom members (bottom stringers and webs) are to comply with the following requirements:

(1) The web depth h of primary members is not to be less than 2 times the depth of the slot for the passage of secondary members (bottom frames and longitudinals), and not to be less than that obtained from the following formula:

$$h = 125l \quad \text{mm}$$

where: l — span of primary member, in m.

(2) The web thickness t of primary members is not to be less than that obtained from the following formula:

$$t = h/100 + 3 \quad \text{mm, not less than 7 mm}$$

where: h — web depth of primary member, in mm.

12.4.3 Side framing of pontoons

12.4.3.1 The section modulus W of frames is not to be less than that obtained from the following formula:

$$W = 9.5shl^2K \quad \text{cm}^3$$

where: s — spacing of frames, in m;

l — span of frame, in m;

h — head taken in calculation, in m; vertical distance measured from the midpoint of span of the frame to deck at side, but not to be less than $0.01L + 0.7$ m, L being length of ship, in m;

K — material factor.

12.4.3.2 The section modulus W of side longitudinals is not to be less than that obtained from the following formula:

$$W = Cshl^2K \quad \text{cm}^3$$

where: s — spacing of longitudinals, in m;

l — span of longitudinal, in m;

h — head taken in calculation, in m; vertical distance measured from the side longitudinal to deck at side, but not to be less than $0.01L + 0.7$ m, L being length of ship, in m;

C — coefficient, taken as:

C = 9.0, for rake-ended bow of pontoon barges;

C = 8.0, for others;

K — material factor.

12.4.3.3 The section modulus W of longitudinally framed web frames is not to be less than that obtained from the following formula:

$$W = CShl^2K \quad \text{cm}^3$$

where: S — spacing of web frames, in m;

l — span of web frame, in m;

h — head taken in calculation, in m; vertical distance measured from the midpoint of span of the web frame to deck at side, but not to be less than $0.01L + 0.7$ m, L being length of ship, in m;

C — coefficient, taken as:

C = 9.5, for rake-ended bow of pontoon barges;

C = 8.5, for others;

K — material factor.

12.4.3.4 Longitudinally framed web frames are to comply with the relevant requirements of 12.4.2.5 of this Section.

12.4.4 Deck framing of pontoons

12.4.4.1 The section modulus W of transversely framed deck beams is not to be less than that obtained from the following formula:

$$W = 4.5shl^2K \quad \text{cm}^3$$

where: s — spacing of deck beams, in m;

l — span of deck beam, in m;

h — head taken in calculation, in m; $h = 0.14p + 0.3$, but not to be less than $0.02L + 0.76$ m, L being length of ship, in m, p being design load, in kPa;

K — material factor.

12.4.4.2 The section modulus W of longitudinally framed deck longitudinals is not to be less than that obtained from the following formula:

$$W = 5shl^2K \quad \text{cm}^3$$

where: s — spacing of deck longitudinals, in m;

l — span of deck longitudinal, in m;
h — head taken in calculation, in m, the same as in 12.4.4.1 of this Section;
K — material factor.

12.4.4.3 The section modulus W of deck girders (including top chords of longitudinal trusses) is not to be less than that obtained from the following formula:

$$W = 5Shl^2K \quad \text{cm}^3$$

where: S — average width of areas supported by girders, in m;
l — span of girders, in m;
h — head taken in calculation, in m, the same as in 12.4.4.1 of this Section;
K — material factor.

12.4.4.4 The section modulus W of deck transverses (including top chords of transverse trusses) is not to be less than that obtained from the following formula:

$$W = 5Shl^2K \quad \text{cm}^3$$

where: S — average width of areas supported by transverses, in m;
l — span of transverses, in m;
h — head taken in calculation, in m, the same as in 12.4.4.1 of this Section;
K — material factor.

12.4.4.5 Primary structural members of deck (including deck girders and transverses) are to comply with the following requirements:

(1) The web depth h of primary members is not to be less than 2 times the depth of the slot for the passage of secondary members (deck beams and longitudinals), and not to be less than that obtained from the following formula:

$$h = 58.5l \quad \text{mm}$$

where: l — span of primary member, in m.

(2) The web thickness t of primary members is not to be less than that obtained from the following formula:

$$t = h/100 + 3 \quad \text{mm, not less than 7 mm}$$

where: h — web depth of primary members, in mm.

12.4.4.6 Where wheeled vehicles are stowed on the deck, the deck framing is also to comply with the relevant requirements in Section 21, Chapter 2 of this PART.

12.4.4.7 Where containers are carried on the deck, stacking devices are to be fitted on supporting members, and the strength of deck framing is to be checked by direct calculation. The static load of containers is to be taken as the load in calculation, and permissible stresses are as follows:

Permissible normal stress $[\sigma] = 0.5R_{eH}$
Permissible shear stress $[\tau] = 0.292\ R_{eH}$

where: R_{eH} — yield stress of material, in N/mm^2.

12.4.5 Truss structure of pontoon barges

12.4.5.1 Pontoon barges are to be fitted with trusses extending either fore and aft or athwartships for the support of hull structure.

12.4.5.2 A truss is comprised of top and bottom girders, pillars and diagonal bracings.

12.4.5.3 The top and bottom girders of longitudinal trusses are deck and bottom girders respectively.

12.4.5.4 The top and bottom girders of transverse trusses are deck transverses and bottom webs respectively.

12.4.5.5 Pillars are to comply with the relevant requirements of Section 10, Chapter 2 of this PART, and the load P acting on pillars is to be taken as the greater of the values obtained from the following formulae:

$$P_1 = pa_1b_1 \quad \text{kN}$$
$$P_2 = 10D\ a_2b_2 \quad \text{kN}$$

where: p — design cargo load, in kPa;
a_1 — average length of deck area supported by pillar, in m;
b_1 — average width of deck area supported by pillar, in m;
D — moulded depth, in m;
a_2 — average length of bottom area supported by pillar, in m;
b_2 — average width of bottom area supported by pillar, in m.

12.4.5.6 Diagonals are generally to have an angle of inclination with the horizontal of 45º, and a cross-sectional area of generally 50% of that of the adjacent pillar.

Section 5 STRENGTHENING AT ENDS OF SHIP

12.5.1 General requirements

12.5.1.1 The ends of barges with general sea-going-ship-shaped bow forms are to be strengthened in accordance with Section 15, Chapter 2 of this PART.
12.5.1.2 The ends of fore rake end pontoon barges are to be strengthened in accordance with this Section. Figure 12.5.1.2 shows the shape and structural arrangement of a typical fore rake end.

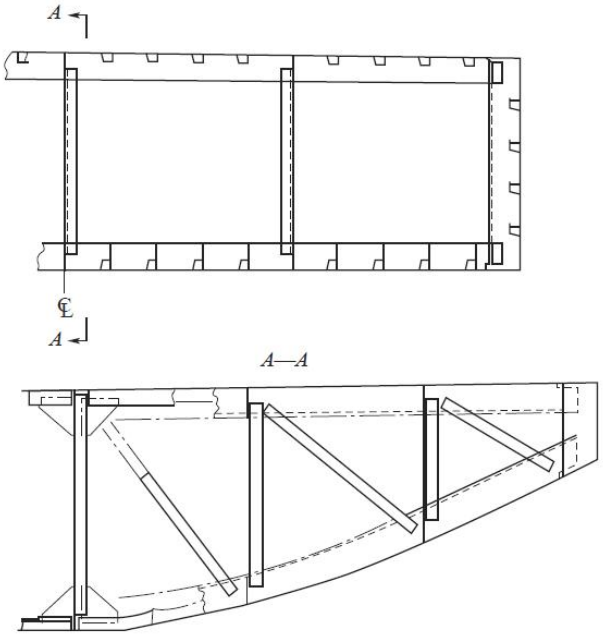

Figure 12.5.1.2

12.5.2 Structural requirements for fore rake end
12.5.2.1 The structural requirements for fore rake end apply to the bottom forward plating of the forward rake from the forward headlog to the lower turn of the rake. Where the collision bulkhead is located aft of the lower turn of the rake, these requirements apply to the bottom forward plating of the forward rake from the forward headlog to the collision bulkhead.
12.5.2.2 The span of bottom longitudinals is not to exceed 2.5 m. Bottom longitudinals may be supported by transverse bulkheads or bottom webs.
12.5.2.3 The span of bottom frames is not to exceed 2.5 m. Bottom frames may be supported by longitudinal bulkheads or bottom girders.
12.5.2.4 The scantlings of primary members are to comply with the relevant requirements for pontoons in Section 4 of this Chapter and in addition, the following requirements:
(1) In general, the web depth of primary members is not to be less than 2.5 times the depth of the slot for the passage of secondary members.
(2) The web depth h of primary members is not to be less than that obtained from the following formula:

$$h = Cl \quad \text{mm}$$

where: l — span of primary members, in m;
C — coefficient, taken as follows:
83.5 for deck transverses;
125 for side transverses;
156 for bottom webs.
12.5.2.5 The bottom shell plating thickness is to be maintained up to the summer load waterline for the rake plating. Above this point the thickness may be tapered to that of the side shell requirements from a point not less than 1 m above the load waterline.

12.5.3 Strengthening of structures of bottom forward against slamming
12.5.3.1 The structures of bottom forward are to be strengthened against slamming in accordance with 2.15.3 of Section 15, Chapter 2 of this PART.
12.5.3.2 Where pontoon barges are towed or pushed at a speed of less than 10 kn and minimum fore draught equal to or greater than $0.01L$ (L being length of ship, in m), with trim being kept at zero, the requirements for strengthening of bottom forward in Section 15, Chapter 2 of this PART may be dispensed with.

Appendix METHOD OF CHECKING TRANSVERSE STRENGTH OF PONTOON BARGES

1. General Requirements

1.1 Application

1.1.1 This method is applicable only to the check of transverse strength of pontoon barges in accordance with 12.1.4.7 of this Chapter.

1.1.2 This method is not applicable to the strength assessment of local structures subjected to a concentrated load (e.g. large foundation, heavy cargo support and struts).

2. Loads

2.1 Load types

2.1.1 Only the effects of maximum permissible deck load and external water pressure are taken into account for design conditions of transverse strength. The effects of hull girder bending moments (both vertical and horizontal ones) are not taken into account.

2.1.2 The load due to external water pressure consists of hydrostatic pressure and hydrodynamic wave pressure as follows:

at baseline: $P_B = 10d \pm 1.5C$ kN/m^2

at waterline: $P_w = \pm 3C$ kN/m^2

at side top: $P_s = 3P_0$ kN/m^2

where: C – see 2.2.3.1 of Section 2, Chapter 2;

d – draught, in m;

P_0 – to be calculated as follows:

$P_0 = C - 0.67(D - d)$ kN/m^2;

D – moulded depth, in m.

In order to take account of the effects of beam sea acting along the ship's length in local areas, such effects are simulated by applying asymmetric external water pressure on both sides for design conditions. A superimposition of hydrostatic pressure and wave pressure may be assumed on one side and the effects of hydrostatic pressure and reverse hydrodynamic wave pressure on the other side (C being taken negative in the above formula), where any value below zero is to be taken as zero.

The distribution of load effects is shown in Figure 2.1.2.

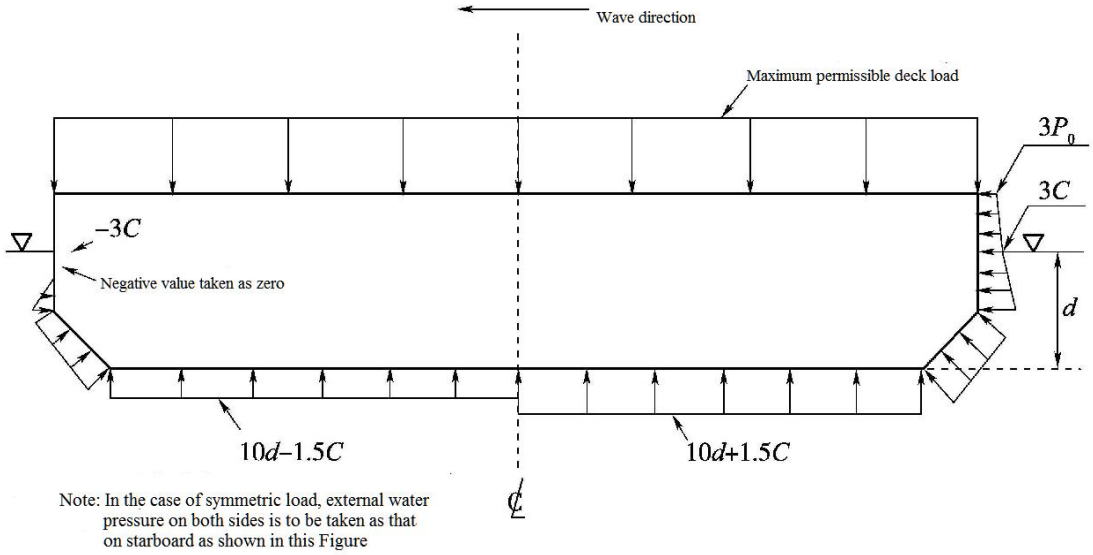

Figure 2.1.2

2.1.3 The following two conditions are taken into account for design conditions:

(1) **Symmetric condition**: Maximum permissible deck load+ external hydrostatic pressure + hydrodynamic wave pressure acting symmetrically inwards on both sides;

(2) **Asymmetric condition**: Maximum permissible deck load + external hydrostatic pressure + antisymmetric hydrodynamic wave pressure acting inwards on one side and outwards on the other side.

3. Structural Models

3.1 Structural modelling

3.1.1 Model extent

① Longitudinal direction: In general, a typical midship hold/tank is to be taken for analysis, with fore and aft end faces (A and B) being at transverse bulkheads covered by the model;

② Transverse direction: Total breadth of the ship;

③ Vertical direction: Total moulded depth.

See Figure 3.1.1.

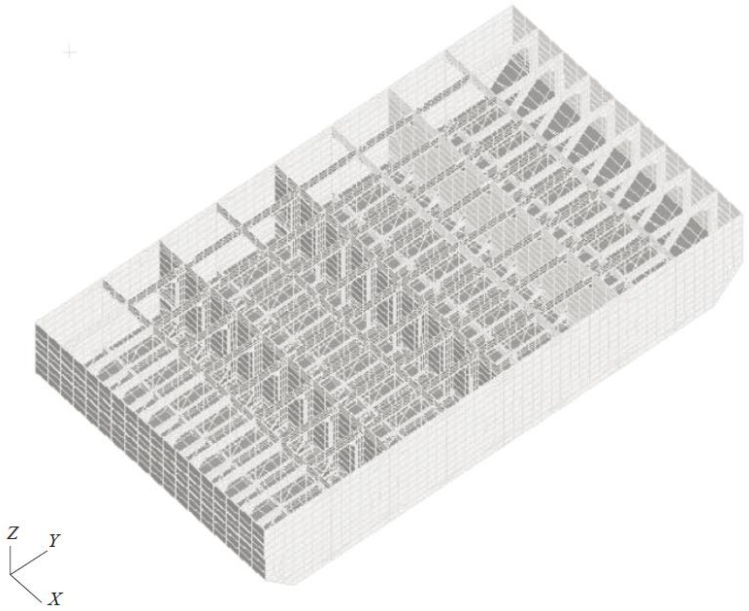

Figure 3.1.1 Model Extent (deck not shown)

3.1.2 Elements and meshing size of models

3.1.2.1 The elements and meshing size of models are to be in accordance with those specified for general finite element hold models, refer to 1.5.6, Chapter 1 of this PART.

3.1.2.2 The diagonals of transverse trusses are generally simulated by rod elements.

3.1.3 Boundary conditions

3.1.3.1 All nodes at edges of fore and aft end transverse bulkheads are to be restrained for 3 linear deflections, see Figure 3.1.3.1.

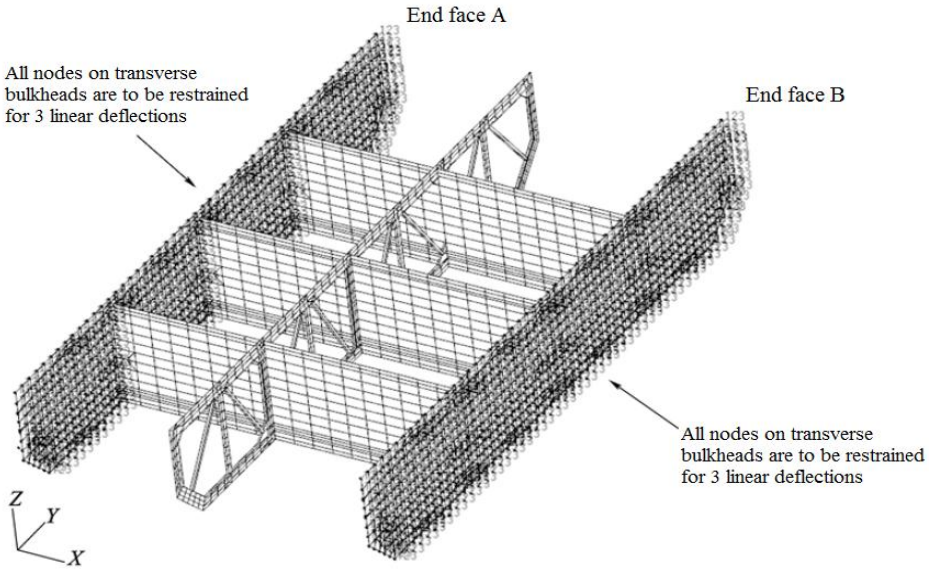

Figure 3.1.3.1 Boundaries Conditions of Model

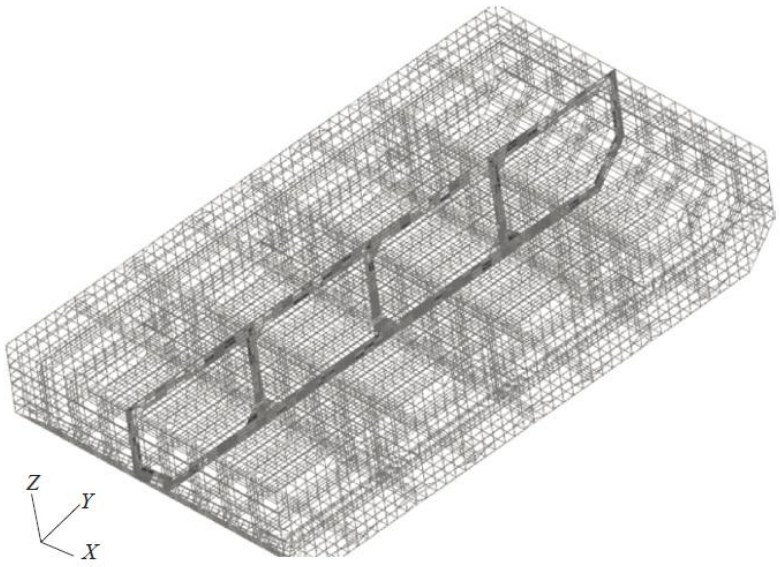
4. Strength Assessment

4.1 General requirements

4.1.1 Assessment of results

4.1.1.1 The range of values for assessment of the results of finite element analysis is to be based on one of the web frames of the model, see Figures 4.1.1.1.



Figures 4.1.1.1

4.1.1.2 For floors and beam webs, the average shear stress based on the total height of webs may be taken as the shear stress in calculation.

4.2 Assessment of yield strength

4.2.1 Strength criteria

4.2.1.1 In all conditions, the calculated stress of individual structural members is not to be greater than the corresponding permissible values given in Tables 4.2.1.1(1) and (2).

Plate Element **Tables 4.2.1.1(1)**

Structural member	$[\sigma_e]$	$[\tau]$
Side transverse web, longitudinal bulkhead vertical girder web	170/K	–
Deck transverse web, bottom floor	170/K	90/K

Beam and Rod Elements **Tables 4.2.1.1(2)**

Structural member	$[\sigma_{rod}]$
Beam element simulating web faceplate of strength member of transverse web frame or beam fitted on transverse members	170/K
Cross tie of transverse truss	141/K

where: σ_e – equivalent stress of plate element (i.e. Von Mises stress), in N/mm^2;

$$\sigma_e = \sqrt{\sigma_x^2 + \sigma_y^2 - \sigma_x\sigma_y + 3\tau_{xy}^2}$$, based on membrane stress at centroid of the element

σ_x – stress of element in direction X, in N/mm^2;
σ_y – stress of element in direction Y, in N/mm^2;
τ_{xy} – shear stress of element in plane XY, in N/mm^2;
τ – average shear stress based on the total height of webs, in N/mm^2;
σ_{rod} – axial stress of rod element or normal stress of beam element (excluding bending stress component), in N/mm^2;
K – material factor.

CHAPTER 13 FLOATING CRANES

Section 1 GENERAL PROVISIONS

13.1.1 Application

13.1.1.1 This Chapter applies to single-deck crane barges with both deck and bottom being framed longitudinally.

13.1.1.2 Those not covered in this Chapter are to comply with the relevant requirements of Chapter 2 of this PART.

13.1.2 Class notation

13.1.2.1 Floating cranes complying with the requirements of this Chapter will be eligible to be assigned the class notation of Floating Crane.

13.1.3 Definitions

13.1.3.1 Fore end and aft end: The fore end and aft end of non-self-propelled floating cranes are to be determined according to their operation conditions. During transit, the floating cranes are to be treated as ordinary ships with the fore end of the hull in the forward direction being called the fore end and the opposite end the after end. In conditions other than transit, the end where the crane jib is fitted is called the fore end and the opposite end the aft end.

13.1.4 Arrangement and structures

13.1.4.1 The continuous longitudinal members of the hull are to be continuous from the fore end to the aft end as far as possible.

13.1.4.2 Two or more continuous longitudinal bulkheads (or longitudinal trusses) are to be fitted from the fore end to the aft end.

13.1.4.3 One transverse watertight bulkhead is to be fitted at a suitable position at each end of the barge. Between the end bulkheads, at least one intermediate transverse watertight bulkhead is to be fitted for barges not exceeding 50 m in length, and at least two intermediate transverse watertight bulkheads are to be fitted for barges exceeding 50 m in length. Such transverse bulkheads are to be arranged reasonably uniform.

13.1.4.4 Longitudinal or transverse supporting bulkheads or other effective structures with sufficient strength and rigidity are to be fitted underneath the cranes to provide adequate support. Such strengthened structures are to be so arranged as to effectively transmit stresses. The deck plating in way is to be increased in thickness or fitted with doublers. The thickness of doublers is not to be less than that of the deck plating. In addition, local strengthening is to be provided to the hull structure in way of other deck machinery or where heavy loads are imposed.

Section 2 LONGITUDINAL STRENGTH

13.2.1 General requirements

13.2.1.1 The longitudinal strength is to comply with the relevant requirements in Section 2, Chapter 2 of this PART. Transit and lifting conditions are to be taken into account.

13.2.1.2 For fixed type floating crane, where the still water bending moment obtained from calculation is a sagging moment in lifting conditions, an additional bending moment (sagging moment) induced by the maximum horizontal component force which is imposed on the hull structure by the maximum load lifted is to be added.

13.2.1.3 For lifting conditions, the wave bending moment and wave shear force regarding the intended area of operation may be determined according to Section 2, Chapter 2 of PART TEN.

Section 3 SHELL PLATING

13.3.1 Minimum thickness

13.3.1.1 The minimum thickness t of shell plating is not to be less than that obtained from the following formula:

$$t = 0.044L + 5.6 \quad \text{mm}$$

where: L — length of ship, in m.

13.3.2 Bottom shell

13.3.2.1 The thickness t of bottom shell plating within $0.5L$ amidships is not to be less than that obtained from the following formula:

$$t = 1.32s\sqrt{LK} + 2.5 \quad \text{mm}$$

where: s — spacing of longitudinals, in m;
L — length of ship, in m;
K — material factor.

13.3.3 Side shell plating

13.3.3.1 The thickness t of side shell plating within $0.5L$ amidships is not to be less than that obtained from the following formula:

$$t = 1.27s\sqrt{LK} + 2.5 \quad \text{mm}$$

where: s — spacing of frames, in m;
L — length of ship, in m;
K — material factor.

Section 4 DECKS

13.4.1 Thickness of deck plating

13.4.1.1 The thickness t of strength deck plating within $0.5L$ amidships is not to be less than that obtained from the following formula:

$$t = 8.75s\sqrt{K}+2.5 \quad \text{mm}$$

where: s — spacing of longitudinals, in m;
K— material factor.

13.4.1.2 The thickness t of strength deck plating outside $0.5L$ amidships is not to be less than that obtained from the following formula:

$$t = 7.13s\sqrt{K}+2.5 \quad \text{mm}$$

where: s — spacing of longitudinals, in m;
K— material factor.

13.4.1.3 The thickness of deck plating in the cargo area is, in addition, not to be less than that obtained from the following formula:

$$t = 4.5s\sqrt{hK} \quad \text{mm, but not less than 6 mm}$$

where: s — spacing of beams or longitudinals, in m;
h — design head, in m, to be taken as $0.14p + 0.3$, p being the design load, in kPa;
K — material factor.

Section 5 SINGLE BOTTOMS

13.5.1 Centre keelson

13.5.1.1 Floating cranes are to be provided with a centre keelson, with side keelsons being fitted on each side of the centre keelson, spaced not more than 2.5 m apart.

13.5.1.2 The web thickness t and the sectional area A of the face plate of the centre keelson are not to be less than:

$$t = 0.065L + 5 \quad \text{mm}$$
$$A = 0.60L + 9 \quad \text{cm}^2$$

where: L — length of ship, in m.

13.5.2 Side keelsons

13.5.2.1 The web thickness t and the sectional area A of the face plate of side keelsons are not to be less than:

$$t = 0.065L + 5 \quad \text{mm}$$
$$A = 0.24L + 10 \quad \text{cm}^2$$

where: L — length of ship, in m.

13.5.3 Plate floors

13.5.3.1 The spacing of plate floors is not to exceed 2.5 m.

13.5.3.2 The section modulus W of plate floors is not to be less than that obtained from the following formula:

$$W = 4Shl^2K \quad \text{cm}^3$$

where: S — spacing of floors, in m;
K — material factor;
h — design head, in m, to be taken as d or $0.66D$, whichever is the greater (d and D being draught and moulded depth respectively, in m);
l — span of floor, in m.

13.5.3.3 The web depth h of floors is not to be less than that obtained from the following formula and in addition, this depth is to be greater than 2.5 times the depth of the slot for the passage of longitudinals:

$$h = 60l_1 \quad \text{mm}$$

where: l_1 — horizontal distance between longitudinal bulkheads or between the longitudinal bulkhead and side shell, in m.

13.5.4 Bottom longitudinals

13.5.4.1 The section modulus W of bottom longitudinals is not to be less than that obtained from the following formula:

$$W = 11.90shl^2K \quad \text{cm}^3$$

where: s — spacing of longitudinals, in m;
K — material factor;
h — design pressure head, in m, to be taken as d or $0.66D$, whichever is the greater (d and D being draught and moulded depth respectively, in m);
l — span of longitudinal, in m.

Section 6 DOUBLE BOTTOMS

13.6.1 General requirements

13.6.1.1 Where double bottoms are provided, the height h of the double bottom is to be determined by the following formula, but not to be less than 700 mm:

$$h = b/18 \quad \text{mm}$$

where: b — horizontal distance between longitudinal bulkheads (or longitudinal trusses), in mm.

13.6.1.2 The thickness of the centre girders, side girders, plate floors and inner bottom plating within the machinery space is to be increased by 2 mm above that obtained from the respective formulae given below in this Section.

13.6.2 Centre girders

13.6.2.1 The thickness t of centre girders is not to be less than that obtained from the following formula:

$$t = 0.05L + 4 \quad \text{mm}$$

where: L — length of ship, in m.

13.6.3 Side girders

13.6.3.1 The thickness t of side girders is not to be less than that obtained from the following formula:

$$t = 0.60\sqrt{L} + 2 \quad \text{mm}$$

where: L — length of ship, in m.

13.6.4 Plate floors

13.6.4.1 The thickness t of plate floors is not to be less than that obtained from the following formula:

$$t = 0.60\sqrt{L} + 2 \quad \text{mm}$$

where: L — length of ship, in m.

13.6.5 Inner bottom plating

13.6.5.1 The thickness t of inner bottom plating is not to be less than that obtained from the following formula:

$$t = 0.67s\sqrt{LK} + 2.5 \quad \text{mm}$$

where: s — spacing of the inner bottom longitudinals, in m;
K — material factor;
L — length of ship, in m.

13.6.6 Longitudinals

13.6.6.1 The section modulus of bottom longitudinals is to be determined in accordance with 13.5.4.1 of this Chapter.

13.6.6.2 The section modulus of inner bottom longitudinals is to be 85% of that of the bottom longitudinals.

Section 7 SIDE FRAMING

13.7.1 Side transverses

13.7.1.1 Side transverses are to be fitted in line with plate floors and their section modulus W is not to be less than that obtained from the following formula:

$$W = 9.5Shl^2K \quad \text{cm}^3$$

where: S — spacing of side transverses, in m;
K — material factor;
h — vertical distance, in m, measured from the mid-point of span of the side transverse to upper deck at side;
l — span of side transverse, in m.

13.7.1.2 The web depth h of side transverses is not to be less than that obtained from the following formula and in addition, this depth is to be greater than twice the depth of the slot for the passage of longitudinals:

$$h = 100l \quad \text{mm}$$

where: l — span of side transverse, in m.

Section 8 STRENGTH DECK FRAMING

13.8.1 Strength deck loading

13.8.1.1 The design head h of the strength deck is to be selected from Table 13.8.1.1.

Design Head *h* **Table 13.8.1.1**

Item	Deck longitudinals	Deck girders and deck transverses	Pillars
Design head h, in m	$0.02L + 0.76$	$0.085L - 1.04(D - d)$	$0.098L - 1.1(D - d)$

Note: L is length of ship, D moulded depth and d draught, in m.

13.8.1.2 Where the deck is subject to load, the design head is to be taken as $0.14p$ (p being the design load, in kPa), in m, but not to be less than the corresponding design head h given in Table 13.8.1.1.

13.8.2 Deck girders

13.8.2.1 The section modulus W of deck girders is not to be less than that obtained from the following formula:

$$W = 3.5bhl^2K \quad \text{cm}^3$$

where: b — mean width, in m, of deck area supported by the girder;
K — material factor;
l — span of deck girder, in m;
h — design head of deck, in m, see 13.8.1 of this Section.

13.8.3 Deck transverses

13.8.3.1 Deck transverses are to be fitted in line with side transverses and their section modulus W is not to be less than that obtained from the following formula:

$$W = 3.9ShlK \quad \text{cm}^3$$

where: S — spacing of deck transverses, in m;
K — material factor;
l — span of deck transverse, in m;
h — design head of deck, in m, see 13.8.1 of this Section.

13.8.3.2 The web depth of deck transverses is not to be less than twice the depth of the slot for the passage of longitudinals.

13.8.4 Deck longitudinals

13.8.4.1 The section modulus W of deck longitudinals is not to be less than that obtained from the following formula:

$$W = 8.5shlK \quad \text{cm}^3$$

where: s — spacing of longitudinals, in m;
K — material factor;
h — design head of deck, in m, see 13.8.1 of this Section;
l — span of longitudinal, in m.

Section 9 PILLARS AND TRUSSES

13.9.1 Pillars

13.9.1.1 Pillars are to comply with the relevant requirements of Section 10 of Chapter 2 of this PART, but the design head h of pillars underneath the strength deck is to be determined according to 13.8.1 of this Chapter.

13.9.2 Longitudinal trusses

13.9.2.1 Longitudinal trusses are to be composed of deck girders, keelsons, pillars and diagonals.

13.9.2.2 The sectional area of pillars of the longitudinal trusses is to comply with the requirements of Section 10 of Chapter 2 of this PART.

13.9.2.3 Diagonals of trusses

(1) The angle of inclination of diagonals of trusses is to be about 45°.

(2) The sectional area of diagonals of trusses is not to be less than 0.5 times that of the pillars calculated according to Section 10 of Chapter 2 of this PART and the ratio of the length of the diagonal to its minimum sectional radius of inertia is not to exceed 120.

CHAPTER 14 DREDGERS

Section 1 GENERAL PROVISIONS

14.1.1 Application

14.1.1.1 This Chapter applies to self-propelled or non-self-propelled steel dredgers with a single deck, including:

(1) trailing suction dredger;
(2) cutter suction/cutter wheel dredger;
(3) bucket dredger;
(4) grab dredger;
(5) hopper barge;
(6) reclamation craft;
(7) split hopper dredger;
(8) split hopper barge.

Dipper dredgers may be referred to the requirements given in this Chapter and are to be adequately strengthened.

14.1.1.2 Those not covered in this Chapter are to comply with the relevant requirements of Chapter 2 of this PART.

14.1.1.3 The provisions of this Chapter are applicable to the following proportions of principal dimensions of dredgers:

For hopper dredgers: $B/D \leq 3$

For other types of dredgers: $B/D \leq 5$

Where any of the above values is exceeded, the transverse strength is to be checked by direct calculation.

14.1.2 Class notations

14.1.2.1 Dredgers complying with the requirements of this Chapter will be eligible to be assigned one of the following class notations:

(1) for trailing suction dredgers: Trailing Suction Dredger;
(2) for cutter suction dredgers: Cutter Suction Dredger;
(3) for cutter wheel dredgers: Cutter Wheel Dredger;
(4) for bucket dredgers: Bucket Dredger;
(5) for grab dredgers: Grab Dredger;
(6) for reclamation craft: Reclamation Craft;
(7) for dipper dredgers: Dipper Dredger;
(8) for hopper barges: Hopper Barge;
(9) for split hopper dredgers: Split Hopper Dredger;
(10) for split hopper barges: Split Hopper Barge;
(11) for back-hoe dredgers: Back-hoe Dredger.

14.1.2.2 Dredgers whose bottom structure has been specially strengthened in accordance with the requirements of Section 7 of this Chapter regarding bottom strengthening for operating aground are to be assigned the following special feature notation:

Bottom Strengthened for Operating Aground.

14.1.3 Plans and documents

14.1.3.1 In addition to the plans and documents required in Section 1, Chapter 2 of this PART, those covering the following items are to be submitted for approval:

(1) Sections through hoppers, pump rooms, dredging machinery spaces and wells;
(2) Hopper and well bulkheads (including sloping bottom structure) and associated regions;
(3) Scarfing arrangements at hopper and well bulkheads (including sloping bottom structure);
(4) Plans of any special arrangements for dismantling, storage and re-assembly (where dredging equipment is stored during voyages);
(5) Seats of dredging equipment (directly affecting the primary hull structure) together with their supporting structures;
(6) for split hopper barges and split hopper dredgers:
① Structure of junction piece of hydraulic installation;
② Deck hinges, deckhouse hinges (appropriate strength calculations are submitted for information);

③ Connection of hinges to hull structure;
④ Connection of junction piece of hydraulic installation to hull structure;
⑤ Longitudinal load-bearing plating in bottom plane and deck plane;
⑥ Longitudinal load-bearing plating of deckhouse and its connection to hull structure;
⑦ Transverse load-bearing plating.

14.1.3.2 The following plans and documents are to be submitted for information (where applicable):
(1) Arrangement of dredging equipment (including the design load of dredging equipment).

14.1.4 Definitions

14.1.4.1 **Hopper:** A hopper is a hold designed to carry dredged spoil and arranged to enable such spoil to be automatically discharged through doors in the bottom of the dredger or hopper barge.

14.1.4.2 **Box keel:** The box keel is a built-up box-shaped structure on the centreline, consisting of bottom plating, side plating in the hopper and internal framing, arranged longitudinally at the lower portion, and between the fore and aft end bulkheads, of the hopper or hoppers.

14.1.4.3 **Cross beam:** The cross beam is a built-up beam spanning transversely the longitudinal bulkheads or hatch coaming of the hopper within the lines of deck openings.

14.1.4.4 **Longitudinal cross beam:** The longitudinal cross beam is a longitudinal built-up beam spanning longitudinally the fore and aft end bulkheads of the hopper within the lines of deck openings.

14.1.4.5 **Well:** The recess or well in the hull of dredgers for arranging the dredging gear.

14.1.4.6 **Split hopper barge or split hopper dredger:** A hopper barge or hopper dredger composed of two independent half hulls separated longitudinally along the hull, with the half hulls being connected by deck hinges and hydraulic installations at the fore and aft transverse bulkheads of the hopper.

Section 2 LONGITUDINAL STRENGTH

14.2.1 General requirements

14.2.1.1 The provisions of this Section are applicable to dredgers and barges 65 m or over in length. The requirements for longitudinal strength of split hopper dredgers and barges are given in Section 9 of this Chapter.

14.2.1.2 The continuous longitudinal members such as longitudinal bulkheads of hoppers, box keels and well bulkheads are to be so arranged as to ensure smooth transition at the break, and abrupt changes of section are to be avoided.

14.2.1.3 For dredgers and barges complying with the requirements of 14.1.1.1, the strength of large openings at hoppers need not be checked.

14.2.2 Bending strength of hull girders

14.2.2.1 The midship section modulus is to comply with the following requirements:
(1) The minimum midship section modulus W_o is not to be less than that obtained from the following formula:

$$W_0 = CL^2B(C_b + 0.7)K \quad \text{cm}^3$$

where: C — coefficient, to be determined according to 2.2.3.1 of Section 2, Chapter 2 of this PART;
L — length of ship, in m;
B — breadth of ship, in m;
C_b — block coefficient at design summer load waterline, but to be taken as not less than 0.6;
K — material factor.

The value of W_o is to be generally maintained throughout 0.4L amidships. However, it may be reduced away from the midship point provided that it complies with the requirements in (2) below.
(2) The section modulus W at deck, keel and top of hopper hatch coaming (where applicable) in way of each transverse section within 0.4L amidships is not to be less than that obtained from the following formulae:

For dredging condition: $W = \dfrac{M_{sd} + M_w}{[\sigma]} \times 10^3$ cm^3

For transit condition: $W = \dfrac{M_s + M_w}{[\sigma]} \times 10^3$ cm^3

where: M_{sd} — still water bending moment in dredging, in kN·m, to be determined according to 14.2.5.1 of this Section;

M_s — still water bending moment in transit, in kN·m, to be determined according to 14.2.5.1 of this Section;

M_w — wave bending moment, in kN·m, to be determined according to 2.2.3.1 of Section 2, Chapter 2 of this PART, which is to comply with relevant requirements of 2.2.1.2 of Section 2, Chapter 2 of this PART;

$[\sigma]$ — permissible bending stress, in N/mm², to be in compliance with 2.2.5.4(2) of Section 2, Chapter 2 of this PART.

14.2.3 Midship section moment of inertia

14.2.3.1 For hopper dredgers and hopper barges, the midship section moment of inertia I about the horizontal neutral axis is not to be less than that obtained from the following formula:

$$I = 3.5W_0 L / K \quad \text{cm}^4$$

where: W_0 — midship section modulus, in cm³, as required in 14.2.2.1(1) of this Section;

L — length of ship, in m;

K — material factor.

14.2.4 Shear strength of hull girders

14.2.4.1 For hopper dredgers and hopper barges, the shear stress is to be checked.

14.2.4.2 The shear stress τ at hull sections near fore and aft hopper end bulkheads is to comply with the following requirements:

For dredging condition: $\tau = \dfrac{|F_{sd} + F_w|}{2Dt} \le [\tau]$ N/mm²

For transit condition: $\tau = \dfrac{|F_s + F_w|}{2Dt} \le [\tau]$ N/mm²

where: F_{sd} — still water shear force when dredging, in kN, to be calculated in accordance with 14.2.5.1 of this Section;

F_s — still water shear force in transit, in kN, to be calculated in accordance with 14.2.5.1 of this Section;

F_w — wave shear force, to be calculated in accordance with 2.2.3.2 of Section 2, Chapter 2 of this PART, which is to comply with relevant requirements of 2.2.1.2 of Section 2, Chapter 2 of this PART;

D — moulded depth, in m;

t — sum of mean thicknesses of side plating and longitudinal bulkhead plating respectively, or mean thickness of side plating, in mm;

$[\tau]$ — the same as that in 2.2.6.2 of Section 2, Chapter 2 of this PART, but $[\tau]$ = 110 N/mm² where higher tensile steel is adopted partially for the hull.

Where the shear stress obtained is greater than $[\tau]$, the thickness of shell plating is to be increased. The strengthening along the length of ship is to be extended beyond both hopper end bulkheads for a distance of not less than 0.04L (L being length of ship, in m).

14.2.5 Design still water bending moment and design still water shear force

14.2.5.1 The still water bending moment and still water shear force of each transverse section of hull girders are to be calculated in accordance with the following dredging condition and transit condition, taking the influence of departure and arrival into account:

(1) maximum loaded condition corresponding to maximum dredging draft;

(2) where more than one hopper are fitted, the partially loaded conditions when the hoppers are not emptied simultaneously;

(3) transit condition at summer load waterline draft;

(4) ballast transit condition with hopper spaces being empty, if applicable;

(5) loading conditions which are more severe than above ones.

14.2.6 Calculation of midship section modulus and moment of inertia

14.2.6.1 When calculating the midship section modulus and moment of inertia, the following requirements are to be complied with:

(1) The strength deck and all continuous longitudinal members below it may be considered in the calculation of the midship section modulus and moment of inertia.

(2) For continuous hatch coamings, where efficiently supported by the longitudinal bulkheads or deep webs, 100% of their sectional areas may be considered in the calculation, otherwise only 80% of their sectional areas may be considered.
(3) For longitudinal cross beams with smooth transition at their ends, 60% of their sectional areas may be considered.
(4) For box keels with smooth transition at their ends, 85% of their sectional areas may be considered.
(5) Where the openings cut in the web of longitudinal girders exceed 20% of the height of the web, the sectional areas of the openings are to be deducted.
In general, the sectional areas of the overflows at side need not be deducted, provided the overflows comply with the requirements of 14.10.3.1, Section 10 of this Chapter.

Section 3 SHELL ENVELOPE PLATING

14.3.1 Bottom shell

14.3.1.1 The thickness of bottom shell plating of hopper dredgers and barges is to be 15% greater than that required in 2.3.1.2 and 2.3.1.3 of Section 3, Chapter 2 of this PART.

14.3.2 Plate keel

14.3.2.1 Where a well or a hopper door is provided on the longitudinal centerline, a plate keel is to be fitted on each side of the well or the hopper door opening. The width of each plate keel is not to be less than half that required in 2.3.2.1 of Section 3, Chapter 2 of this PART. The position of the plate keel is to be indicated on the docking plan.
14.3.2.2 The thickness of the plate keel is to be 2 mm greater than that required for the bottom shell.

14.3.3 Openings in shell plating

14.3.3.1 The corners of hopper door openings or wells in the bottom are to be rounded, and the ratio of the radius of corners to the width of openings is not to be less than 1/10.
14.3.3.2 Openings are generally not to be cut in sheer strakes, otherwise the requirements of 14.10.3.1, Section 10 of this Chapter are to be complied with.

14.3.4 Local strengthening and special requirements

14.3.4.1 The thickness of the bottom shell connected to the hopper longitudinal bulkheads or to the well bulkheads is to be 1 mm greater than that required in this Section, and the width of which is not to be less than that of the plate keel.
14.3.4.2 Where the hopper is extended outside 0.4L amidships, the thickness of side shell amidships is to be maintained for at least two frame spaces beyond both end bulkheads of the hopper and gradually tapered to the thickness of fore and aft ends of the ship.
14.3.4.3 The thickness of the shell plating in way of the suction pipe connections of trailing suction dredgers and in way of the positioning spuds of cutter suction dredgers or bucket dredgers, as well as the thickness of well bulkheads are to be 2 mm above that required for side shell.
14.3.4.4 In areas where the drag head may run against bilge and side shell, strengthening is to be provided, e.g. plating of increased thickness, additional framing or fitting of fenders.
14.3.4.5 Where suction pipe ladder wells cut into shell plating are provided at the side of trailing suction dredgers, a sheathing long enough along the length of the ship is to be provided. The sheathing thickness is not to be less than that of shell plating, and the sheathing breadth is to cover the ladder wells. The sheathing is to be strengthened by side transverses and stringers at its inner side. The stringers are to be sufficiently sized to bear the load transferred from side longitudinals so as to keep the continuity of longitudinal structural members.
14.3.4.6 The well width of bucket dredgers is to be such that the overhanging part of the bucket chain will not chafe the lower well wall under the maximum allowable working inclination of the hull.
14.3.4.7 The thickness of the bottom shell of bucket dredgers that is connected to end well bulkheads is to be increased by 50% for a distance not less than twice the well width along the breadth of the ship, and for at least two frame spaces from both end bulkheads along the length of the ship.
14.3.4.8 Fenders are to be fitted to the longitudinal bulkheads of wells in bucket dredgers to guard against damages due to the movement of bucket ladders.

Section 4 DECKS AND DECK FRAMING

14.4.1 Strength deck

14.4.1.1 The thickness of midship strength deck plating is, in addition to complying with the requirements of Section 2 of this Chapter, is to be increased by 1 mm above that required in Section 4, Chapter 2 of this PART.

14.4.1.2 In the case of dredgers having closed hopper spaces, the thickness of deck plating in way of the hopper spaces is to be adequately increased.

14.4.2 Half sectional area of deck

14.4.2.1 For dredgers and hopper barges less than 65 m in length, the half sectional area a of midship strength deck plating is not to be less than that obtained from the following formula:

For box-shaped ship:

$$a = C_1 \frac{B}{D} - C_2 D t_1 + C_3 (B - b)\, t_2 \quad \text{cm}^2$$

For hopper barge:

$$A = C_1 \frac{B}{D} - 1.6 D t_1 - 3.05 D t_3 \quad \text{cm}^2$$

where: B — breadth of ship, in m;

D — moulded depth, in m;

b — the width of well or opening at the midship bottom, in m;

t_1 — the thickness of side shell required in 2.3.4 of Section 3, Chapter 2 of this PART, in mm, t_1 is to be included in the thickness of longitudinal bulkheads for ships having continuous longitudinal bulkheads within 0.4L amidships;

t_2 — the thickness of continuous inner bottom plating within 0.4L amidships, in mm;

t_3 — the thickness of web of continuous longitudinal hatch coamings, in mm;

C_1 = $0.065L^2 - L + 9$ (L being length of ship, in m);

C_2, C_3 — coefficient, to be taken from Table 14.4.2.1.

Values of C_2 and C_3 **Table 14.4.2.1**

Type of ship structure	C_2	C_3
Box-shaped ship without continuous longitudinal bulkhead within 0.4L amidships	2.15	0.32
Box-shaped ship with continuous longitudinal bulkheads within 0.4L amidships	3.07	0.205

The above-mentioned half sectional area of deck plating is the sum of sectional areas of continuous longitudinal members, such as deck plating, stringer strakes, deck longitudinals and deck girders, outside the lines of large openings and at one side of the longitudinal midship line of the deck. For longitudinal cross beams having smooth transition at both ends, 60% of their sectional areas may be included.

The thickness of deck plating derived from the half sectional area of decks is not subject to reduction for service categories.

14.4.3 Deck framing

14.4.3.1 Where the deck of side tanks is framed transversely, deck transverses are to be fitted in the plane of web frames in the side tanks, the web height of which is to be 2/3 of that of the web frame, and the web thickness and the face plate area of which are to be the same as those of the web frame.

14.4.3.2 For dredgers having a closed hopper space, the section modulus of deck framing within the hopper region is to be increased by 10% of that required in Section 8, Chapter 2 of this PART.

14.4.3.3 For trailing suction dredgers, the section modulus of deck longitudinals within the hopper and side tank region is to be increased by 20% of that required in Section 8, Chapter 2 of this PART.

14.4.4 Local strengthening

14.4.4.1 For bucket and cutter suction dredgers, the thickness of deck plating connected with the well bulkheads is to be increased by 1 mm, and the width of which is not to be less than that of the plate keel.

14.4.4.2 The plate thickness and framing design of decks connected with heavy dredging machinery seats are to provide sufficient strength and rigidity and where necessary, local strength is to be checked, see the requirements of 14.10.6 of Section 10.

14.4.4.3 The deck plating and deck framing in the following regions are to be sufficiently strengthened:

(1) in way of the main gantry and the bucket ladder gantry;

(2) in way of cutter ladders and of supporting of the gantry (the region in way of supporting of the hydraulically lifted cutter ladders is to have sufficient strength and rigidity and where necessary, local strength is to be checked);
(3) in way of the gantry supporting the suction pipe;
(4) in way of supporting of the spud;
(5) in way of towing bollards;
(6) in way of the winch seating;
(7) in way of the grab machinery;
(8) the thickness of stringer strakes in way of suction pipe ladder wells of trailing suction dredgers is to be increased by 60%, and the increased thickness is to be maintained for at least one frame space from the side transverse at both ends of the well;
(9) in way of other working regions of machinery.

Section 5 BOTTOM FRAMING

14.5.1 General requirements

14.5.1.1 The bottom framing in pump rooms is to be strengthened in accordance with the requirements for machinery spaces.
Where the double bottom is interrupted in the pump room due to the arrangement of dredging pumps, the bottom framing in way is to be specially strengthened.
The requirements for dredging pump seatings are not to be inferior to those for main engine seatings specified in Section 16, Chapter 2 of this PART.
Where the bottom framing is connected with the seatings of other dredging equipment or special machinery, and with the bottom table of grabs or dipper machines as well as the main gantry of bucket dredgers, such bottom framing is to be adequately strengthened.
14.5.1.2 For trailing suction dredgers of 65 m or over in length, a double bottom is, as far as possible, to be arranged from the fore peak bulkhead to the after peak bulkhead except the region of hopper spaces.
14.5.1.3 The double bottom structure is to comply with the requirements of Section 6, Chapter 2 of this PART.
For double bottoms framed longitudinally, the spacing of plate floors is, furthermore, to comply with the requirements for the spacing of web frames in 14.6.2.1, Section 6 of this Chapter.
14.5.1.4 The bottom longitudinal members in hoppers that are tapered to both ends are to be continuous. Additional side girders are to be fitted in the double bottom below the bracket of hopper longitudinal bulkheads and longitudinal well bulkheads. The additional side girders are to be extended for at least 3 frame spaces from the end of brackets.

14.5.2 Single bottom with transverse framing

14.5.2.1 Plate floors are to be fitted to each frame at both sides of side tanks and wells.
The section modulus W, web height h and web thickness t of plate floors are not to be less than those obtained from the following formulae:

$$W=(16.4sdl^2+150)K \quad \text{cm}^3$$
$$h = 110l \quad \text{mm}$$
$$t = (0.01h + 3.5)\sqrt{K} \quad \text{mm}$$

where: s — spacing of floors, in m;
K — material factor;
d — draught, in m;
l — span of floor, in m, the distance measured from the inner surface of shell plating along the face plate of floors to the inner surface of the longitudinal bulkhead or side well bulkhead of the hopper, taken as $0.3B$ for $l < 0.3B$, (B being the breadth of ship, in m).

14.5.2.2 Where the distance between the ship's side and the side bulkhead of the hopper at the bottom exceeds 3.5 m, a side keelson is to be fitted in side tanks. The thickness of the side keelson is to be equal to that of the floor in way.

14.5.3 Single bottom with longitudinal framing

14.5.3.1 The section modulus W of bottom longitudinals is not to be less than that obtained from the following formula:

$$W = 11.5sdl^2K \quad \text{cm}^3$$

where: s — spacing of longitudinals, in m;
K — material factor;
d — draught, in m;
l — span of longitudinal, in m.

The connection of bottom longitudinals to transverse bulkheads or floors is to comply with the requirements of 1.2.6 of Section 2, Chapter 1 of this PART.

14.5.3.2 The section modulus W of floors in side tanks is not to be less than that obtained from the following formula:

$$W = 16.4SdlK \quad \text{cm}^3$$

where: S — spacing of floors, in m;
K — material factor;
d — draught, in m;
l — span of floor, in m, the distance measured from the inner surface of shell plating along the face plate of floors to the inner surface of the hopper longitudinal bulkhead.

The depth of the web of floors in side tanks is not to be less than 1/9 of the span of the floor, and is not to be less than 2.5 times the depth of the slot for the passage of bottom longitudinals. The thickness of the web of floors is not to be less than 0.01 times the depth of the floor plus 4.5 mm.

Where one side keelson is fitted in the side tank, the section modulus of the floors may be reduced by 5%.

14.5.3.3 For box-shaped ships fitted with two longitudinal bulkheads, the floors in side tanks are to comply with the requirements of 14.5.3.2 of this Section.

The section modulus W of floors in the center tank is not to be less than that obtained from the following formula:

$$W = 9SdlK \quad \text{cm}^3$$

where: S — spacing of floors, in m;
K — material factor;
d — draught, in m;
l — span of floor in the center tank, in m, the distance between the longitudinal bulkheads.

The section modulus of floors in the center tank is also not to be less than that of floors in the side tanks. The depth of the web of floors in the center tank is not to be less than 1/12 of the span of the floor, and is not to be less than 2.5 times the depth of the slot for the passage of bottom longitudinals. The thickness of the web of floors is not to be less than 0.01 times the depth of the floor plus 4.5 mm.

14.5.3.4 Vertical stiffeners are to be fitted to the web of floors in way of every bottom longitudinal. The thickness of stiffeners is to be equal to that of the web of floors, and the width is to be 8 times its thickness.

14.5.4 Double bottom with transverse framing

14.5.4.1 Where the distance between the ship's side and the side bulkhead of the hopper at the bottom exceeds 3.5 m, side girders are to be fitted in side tanks, and the thickness of the side girders is to be equal to that of floors in way.

14.5.5 Double bottom with longitudinal framing

14.5.5.1 The section modulus W of bottom longitudinals is not to be less than that required in 14.5.3.1 of this Section.

The section modulus of inner bottom longitudinals is not to be less than 85% of that of bottom longitudinals.

Section 6 SIDE FRAMING

14.6.1 Transverse side framing

14.6.1.1 Side stringers are, as far as practicable, to be fitted in side tanks of hopper barges.

14.6.2 Longitudinal side framing

14.6.2.1 The spacing of web frames is not to be more than $0.01L + 2.5$ m (L being the length of ship, in m). For trailing suction dredgers, the spacing of web frames is also to comply with the requirements for the spacing of hopper strength frame rings.

The section modulus of web frames is to be determined in accordance with the requirements of 2.7.6.2 of Section 7, Chapter 2 of this PART.

Where horizontal cross ties and diagonal braces complying with the requirements of 14.6.3 of this Section are fitted, the section modulus of web frames may be reduced by 50%.

14.6.2.2 Tripping brackets are to be fitted to web frames in way of the cross ties and other positions in accordance with the requirements of 1.2.5.4 of Section 2, Chapter 1 of this PART.

14.6.3 Horizontal cross ties and diagonal braces

14.6.3.1 Where horizontal cross ties or diagonal braces are fitted in the side tanks, the sectional area A and moment of inertia I of which are not to be less than those obtained from the following formulae:

$$A=(1.5abh+10)K \quad \text{cm}^2$$

$$I = 3Al^2/K \quad \text{cm}^4$$

where: a — spacing of cross ties or braces, in m;

b — width supported by the cross tie or brace, in m, i.e. half the sum of lengths of the frame above and below the intersected cross tie or brace;

K — material factor;

h — pressure head under consideration, in m, the distance measured from the supporting point to the top of air pipe;

l — length of the cross tie or brace including the bracket, in m.

Section 7 BOTTOM STRENGTHENING FOR OPERATING AGROUND

14.7.1 Application

14.7.1.1 Where the dredgers are to operate aground or are allowed to be run aground in operation, the bottom structure is to comply with the requirements this Section.

14.7.2 Bottom structure strengthening

14.7.2.1 The thickness of bottom plating is to be 20% more than that required in 2.3.1.2 and 2.3.1.3 of Section 3, Chapter 2 of this PART.

14.7.2.2 Transversely framed single bottom structures are to be strengthened as follows:

(1) Vertical stiffeners are to be fitted at bottom floor webs, spaced not greater than 1.25 m;

(2) The spacing of side keelsons is not to be greater than 2.2 m, and intermediate bulb plate longitudinals with webs of 100 mm × 10 mm or equivalent members are to be fitted.

14.7.2.3 Longitudinally framed single bottom structures are to be strengthened as follows:

(1) Bottom floors are to be spaced generally not greater than 3 frame spacings, and vertical stiffeners having the same thickness as that of bottom floors are to be fitted at bottom longitudinals;

(2) The spacing of side keelsons is not to be greater than 3 bottom longitudinal spacings;

(3) Intercostal frames are to be fitted at the midspan of bottom longitudinals.

14.7.2.4 Transversely framed double bottom structures are to be strengthened as follows:

(1) Solid bottom floors are to be fitted at each frame, with vertical stiffeners spaced generally not greater than 1.25 m;

(2) The spacing of side girders is not to be greater than 2.2 m, and bottom longitudinals are to be fitted at the mid-spacing of bottom girders. The section modulus of bottom longitudinals is to be referred to 2.6.12.2 of Section 6, Chapter 2 of this PART.

14.7.2.5 Longitudinally framed double bottom structures are to be strengthened as follows:

(1) Solid floors are to be spaced generally not greater than 3 frame spacings, and vertical stiffeners having the same thickness as that of solid floors are to be fitted at bottom longitudinals;

(2) The spacing of side girders is generally not to be greater than 4 bottom longitudinal spacings;

(3) Intercostal frames are to be fitted at the midspan of bottom longitudinals.

Section 8 HOPPERS

14.8.1 Application

14.8.1.1 The requirements of this Section for bottom framing are applicable to box-shaped single-bottom hoppers.

14.8.2 Box keels

14.8.2.1 The thickness of side plates and the section modulus of stiffeners of box keels are to comply with the relevant requirements of this Section for hopper bulkheads. Box keels are to be adequately strengthened in way of the hopper plate floors and the bottom end of pillars.
14.8.2.2 Where the box keel is interrupted at the hopper end bulkhead, transitional brackets of a length not less than two frame spaces are to be fitted or other effective means provided to ensure a smooth transition of the box keel.
14.8.2.3 A strength frame ring is to be provided to the box keel in the plane of hopper floors so as to ensure the continuity of transverse strength within the breadth of the ship.

14.8.3 Floors in hoppers (spoil spaces)

14.8.3.1 The depth of hopper floors is not to be less than $0.13B$ (B being the breadth of ship, in m). The spacing of the plate floors is not to be more than 4.5 m, and the spacing of box floors is generally not to be more than 6 m from centre to centre. Where the spacing of box floors is more than 6 m from centre to centre, the depth of the box floors is to be increased appropriately.
14.8.3.2 The web thickness of the plate floors is not to be less than that required in 14.3.1.1, Section 3 of this Chapter. The net cross-sectional area A of the web of plate floors after deducting openings, in the region for a distance equal to half depth of the floor from the ends of the calculated span, is not to be less than that obtained from the following formula:

$$A = 0.93(h_1 Sl - \alpha s_0 h_1 - \rho f S + 0.102p')K \quad \text{cm}^2$$

where: S — spacing of floors, in m;
K — material factor;
l — span of floor, in m, the mean value of the distances, measured between the hopper longitudinal bulkheads along the upper and lower edges of the floor respectively;
h_1 = $\rho(D + h_f) - d + 1.25$, in m, to be taken as d for $h_1 < d$;
ρ — density of spoil, in t/m³, see 14.8.4.2 of this Section;
D — moulded depth, in m;
h_f — vertical distance, in m, measured from the level of the overflow weir to the deck line at side; where the level of the overflow weir is below the deck line at side, the value h_f is negative;
d — draught, in m;
s_0 — area of bottom door, in m²;
f — cross sectional area of box keel, in m²;
p' — load on the pillar in one floor spacing, in kN, to be calculated according to the requirements of 14.8.8.2 of this Section;
α — coefficient:
for ram bottom door, $\alpha = 2$;
for hinged bottom door, $\alpha = 1$;
for drawer bottom door, $\alpha = 0$.

In other regions, the net cross-sectional area A may be reduced by 20%.
14.8.3.3 Vertical stiffeners are to be fitted to the web of plate floors, spaced not more than $80t$ apart (t being the thickness of web, in mm), and the section modulus W of stiffeners is not to be less than that obtained from the following formula:

$$W = 40slK \quad \text{cm}^3$$

where: s — spacing of stiffeners, in m;
K — material factor;
l — span of stiffener, in m.

The upper edge of floors is to be strengthened by means of a flat bar or rolled section.
14.8.3.4 The thickness of side plates of box floors and the section modulus of stiffeners are to comply with the relevant requirements of this Section for hopper bulkheads.

14.8.4 Hopper bulkheads

14.8.4.1 Watertight transverse bulkheads extending from starboard to port are to be provided at both ends of the hopper and the well end.
Both ends of hopper longitudinal bulkheads are to be further extended by means of upper and lower brackets. The upper brackets are to be connected to deck girders or the strength frame ring, while the lower brackets are to be connected to side keelsons or side webs. The length extended is not to be less than two frame spaces, and the height of the brackets is not to be less than 1/4 hopper depth.
14.8.4.2 The thickness t of hopper bulkhead plating is not to be less than that obtained from the following formula, and not less than 8 mm, or not less than 10 mm when a grab is used for loading and unloading:

$$t=3.95s\sqrt{\rho hK}+2.5 \quad \text{mm}$$

where: s — spacing of stiffeners, in m;
K — material factor;
ρ — density of spoil, in t/m³, $\rho = P/V$;
P — the maximum spoil mass, in t, in hopper at maximum dredging draft;
V — hopper volume, in m³, up to the sill of the uppermost overflow weir;
h — vertical distance, in m, measured from the lower edge of bulkhead plating to the level of the uppermost overflow weir, or to the upper edge of hopper coaming where no overflow weir is provided.

14.8.4.3 The thickness of the lowest plating of hopper bulkheads within the height of $0.1D$ from bottom is not to be less than that of the bottom plating in way, D being the moulded depth.

14.8.4.4 For those portions of hopper bulkheads that are liable to wear, a wear addition of 2 mm to the plate thickness may be considered in design.

14.8.4.5 The section modulus W and sectional moment of inertia I of hopper bulkhead stiffeners are not to be less than those obtained from the following formulae:

$$W=8s\rho hl^2K \quad \text{cm}^3$$
$$I = 2.3Wl/K \quad \text{cm}^4$$

where: s — spacing of stiffeners, in m;
K — material factor;
ρ — density of spoil, in t/m³, the same as that in 14.8.4.2;
h — vertical distance, in m, measured from the mid-span of the stiffener to the level of the uppermost overflow weir, or to the upper edge of hopper coaming where no overflow weir is provided;
l — span of stiffener, in m, or distance between the end of the stiffener and the girder or between girders where girders are fitted.

Where horizontal stiffeners are fitted, the scantlings of two top stiffeners are to be the same as those of the third one below the deck.

The ends of the stiffeners are to be bracketed. The scantlings of the brackets are to be determined according to 1.2.6 of Section 2, Chapter 1 of this PART.

14.8.4.6 The section modulus W and sectional moment of inertia I of hopper bulkhead girders are not to be less than those obtained from the following formulae:

$$W=11.7b\rho hl^2K \text{ cm}^3$$
$$I = 2.5Wl/K \quad \text{cm}^4$$

where: b — breadth of area supported by girder, in m;
K — material factor;
ρ — density of spoil, in t/m³, the same as that in 14.8.4.2;
h — vertical distance, in m, measured from the mid-span of the girder to the level of the overflow weir, or to the upper edge of hopper coaming where no overflow weir is provided;
l — span of girder, in m.

Where cross ties or braces are provided as required in 14.6.3, Section 6 of this Chapter, the section modulus of hopper bulkhead girders may be reduced by 50%.

14.8.4.7 The web depth of hopper bulkhead girders is not to be less than 2.5 times that of the cut-outs for the passage of bulkhead stiffeners. The breadth of the face plate of the girders is not to be greater than the web depth or 35 times the thickness of the face plate, whichever is the lesser.

14.8.4.8 Hopper bulkhead girders are to be fitted with tripping brackets as required in 1.2.5.4 of Section 2, Chapter 1 of this PART.

14.8.4.9 For trailing suction dredgers, the section modulus of hopper bulkhead stiffeners and girders may be reduced by 10% of that required in 14.8.4.5 and 14.8.4.6.

14.8.5 Transverse bulkheads and strength frame ring in side tanks

14.8.5.1 Transverse bulkheads or strength frame rings are to be fitted in the centre plane of hopper plate floors or box floors within side tanks.

The strength frame ring is to be composed of floors, web frames, vertical girders on the hopper longitudinal bulkhead, web beam and/or cross ties (if fitted), and the scantlings of which are to comply with the relevant requirements of this Chapter.

Where the spacing of floors in hopper spaces or of transverse bulkheads or strength frame rings in side tanks exceeds the specified limit, the transverse strength of the hopper region is to be checked.

14.8.5.2 Where the transverse bulkheads in side tanks are watertight or deep bulkheads, the bulkhead plating and stiffeners are to comply with the requirements of Section 12 or Section 13, Chapter 2 of this PART.

14.8.5.3 Where the transverse bulkheads in side tanks are non-watertight, the thickness t of bulkhead plating is not to be less than that obtained from the following formula:

$$t = 0.03L + 5.6 \quad \text{mm}$$

where: L — length of ship, in m.

The section modulus of stiffeners on the bulkhead may be deducted by 40% from that of the stiffeners on the watertight bulkhead. Stiffeners are to be fitted with brackets at both ends. However, the sectional area of the stiffeners supporting longitudinals, girders etc. is also to comply with the requirements of Section 11, Chapter 2 of this PART.

14.8.5.4 The transverse bulkheads in side tanks are to be adequately strengthened in way of the connection with the hopper floors.

14.8.6 Hopper web beams and cross beams

14.8.6.1 Web beams or cross beams are to be fitted in the plane of floors in the hoppers (spoil spaces).

14.8.6.2 The section modulus W of hopper web beams is not to be less than that obtained from the following formula:

$$W = (5.75Shl^2 + 0.102CFl)\,K \quad \text{cm}^3$$

where: S — spacing of web beams, in m;

K — material factor;

h — pressure head under consideration, in m, to be taken in accordance with 2.8.1.1 of Section 8, Chapter 2 of this PART;

l — span of web beam, in m, the distance between hopper longitudinal bulkheads where no intermediate pillar is fitted, or the distance between the hopper longitudinal bulkhead and the centreline of the intermediate pillar where an intermediate pillar is fitted;

F — maximum mechanical acting force, in kN, when the bottom door is opened or closed;

C — coefficient:

with intermediate pillar, $C = 100K(1 - K)^2$;

without intermediate pillar, $C = 100K(1 - K)$

where K is the ratio of the distance between the point of the acting force and the nearest end to l.

14.8.6.3 The section moment of inertia I of the hopper web beam is not to be less than that obtained from the following formula:

$$I = 2Wl/K \quad \text{cm}^4$$

where: W, l, K are same as defined in 14.8.6.2 of this Section.

The web depth of hopper web beams is not to be less than twice that of the slot for the passage of longitudinals, and the web thickness is not to be less than 1% of the web depth plus 4 mm.

14.8.6.4 The connection of the hopper web beam to the hopper longitudinal bulkhead is to comply with the requirements of 2.8.7.9 of Section 8, Chapter 2 of this PART.

14.8.6.5 The section modulus W of cross beams is to comply with the requirements of 14.8.6.2 of this Section, where S and l are respectively the face plate breadth and the span of cross beams, in m; where no intermediate pillar is fitted, the span l is the distance between hopper longitudinal bulkheads and where an intermediate pillar is fitted, l is the distance measured from the hopper longitudinal bulkhead to the centreline of the pillar.

Where cross beams support the crane and/or suction pipes, the section modulus is to be increased and is to be determined through calculation. Both ends of the cross beam are to be assumed as rigidly fixed in calculation, and the allowable bending stress is to be taken as $98/K$ N/mm^2.

The total net sectional area A of cross beams after deducting openings is not to be less than that obtained from the following formula:

$$A = 2S(C_1D^2 + C_2l^2) + 20)\,K \quad \text{cm}^2$$

where: S — spacing of floors, in m;

K — material factor;

D — moulded depth, in m;

l — span of floor, in m, to be measured in accordance with the requirements of 14.8.3.2 of this Section;

C_1, C_2 — coefficients, to be taken from Tables 14.8.6.5(1) and (2). Where the value of $C_1D^2 + C_2l^2$ is negative, to be taken as an absolute value.

Value of C_1 **Table 14.8.6.5(1)**

d_1/D \ $(D + h_f)/D$	1.0	1.1	1.2	1.3	1.4	1.5
0.4	-0.1849	-0.2637	-0.3616	-0.4804	-0.6222	-0.7890
0.5	-0.1808	-0.2596	-0.3575	-0.4763	-0.6181	-0.7850
0.6	-0.1727	-0.2515	-0.3494	-0.4682	-0.6100	-0.7768
0.7	-0.1593	-0.2381	-0.3360	-0.4548	-0.5966	-0.7634
0.8	-0.1394	-0.2182	-0.3161	-0.4350	-0.5767	-0.7435

Value of C_2 **Table 14.8.6.5(2)**

d_1/D \ $(D + h_f)/D$	1.0	1.1	1.2	1.3	1.4	1.5
0.4	0.1157	0.1327	0.1497	0.1667	0.1837	0.2007
0.5	0.1083	0.1253	0.1423	0.1593	0.1763	0.1933
0.6	0.1010	0.1180	0.1350	0.1520	0.1690	0.1860
0.7	0.0937	0.1107	0.1277	0.1447	0.1617	0.1787
0.8	0.0864	0.1034	0.1204	0.1374	0.1544	0.1724

Note: $d_1 = d - 1.25$, in m; h_f — see 14.8.3.2 of this Section; C_2 taken from the Table is to be increased by 15% for hinged bottom door.

For $C_1D^2 + C_2l^2 > 0$, the minimum moment of inertia I of cross beams is not to be less than that obtained from the following formula:

$$I = 3Al_1^2/K \quad \text{cm}^4$$

where: A — total sectional area of the cross beam, in cm²;
K — material factor;
l_1 — span of cross beam, in m.

Where the floors in the hopper are spaced more than 4 m apart, the scantlings of the cross beams are to be verified by direct calculation, with openings being deducted from the sectional area. The assumptions for the calculation model and the permissible stresses are the same as above.

14.8.7 Deck girders and longitudinal cross beams

14.8.7.1 The section modulus W of deck girders or longitudinal cross beams supporting the opening/closing mechanism for the bottom doors is not to be less than that obtained from the following formula:

$$W = (5.3bhl^2 + 1.94Fl)\,K \quad \text{cm}^3$$

where: b — mean width of deck area supported by the deck girder, in m, for longitudinal cross beams b being the width of the face plate, in m;
h — pressure under consideration, in m, to be determined according to 2.8.1.1 of Section 8, Chapter 2 of this PART;
K — material factor;
l — span of deck girder or longitudinal cross beam, in m;
F — maximum mechanical acting force, in kN, when the bottom door is opened or closed.

14.8.8 Pillars

14.8.8.1 Where a box keel is fitted, pillars are, in general, to be fitted for connecting the hopper floors to hopper web beams or cross beams. The scantlings of steel tubular pillars are to comply with the requirements of 2.10.2.1 and 2.10.3.1 of Section 10, Chapter 2 of this PART, except that the wall thickness of which is to be 1 mm more than that obtained from 2.10.3.1 of this PART, and not to be less than 7 mm.

14.8.8.2 The load P' supported by the pillar is not to be less than that obtained from the following formula:

$$P' = 7.06abh + \frac{2Fe}{l} + \Delta P \quad \text{kN}$$

where: a — length of deck area supported by the pillar under consideration, in m, or width of the face plate for cross beams;
b — width of deck area supported by the pillar under consideration, in m, or half the length of the face plate for cross beams;
h — considered pressure head of the deck supported by the pillar under consideration, in m, to be taken according to 2.8.1.1 of Section 8, Chapter 2 of this PART;

F — maximum mechanical acting force, in kN, when the bottom door is opened or closed;
e — distance measured from the point of the mechanical acting force to the end of web beam, in m, when the bottom door is opened or closed;
l — span of the web beam or cross beam, in m;
ΔP — the acting force on the crane and/or suction pipe supported by pillars, in kN.

14.8.9 Continuous coamings

14.8.9.1 Coamings are to have a plate thickness of not less than that obtained from 14.8.4.2 of this Section for the longitudinal bulkhead strakes in hoppers.

Horizontal stiffeners of the coaming are to be spaced apart not more than 80 times the plate thickness of the coaming for the lower panel of plating, and not more than 65 times the plate thickness of the coaming for the upper panel of plating. The moment of inertia I of the horizontal stiffener is not to be less than that obtained from the following formula:

$$I = 2Al^2 \quad \text{cm}^4$$

where: A — total sectional area of the horizontal stiffener with attached plating, in cm^2;
l — spacing of coaming brackets, in m.

14.8.9.2 The coamings are to be extended beyond both ends of the hopper for a distance of at least 1.5 times the coaming height in general.

14.8.9.3 The upper edge of the coaming is to be stiffened by a fabricated flange, or an equivalent structure capable of achieving a good rigidity of the coaming.

14.8.9.4 The coaming brackets are to be arranged in way of each deck transverse. The thickness of brackets is to be equal to that of the coaming plating. The width of the lower end of brackets is not to be less than 1/3 times the height of the coaming plating. Where the coaming and the hopper longitudinal bulkhead are not in the same plane, the breadth of the lower end of brackets is not to be less than twice the distance between the hopper longitudinal bulkhead and the coaming, and supporting brackets having a thickness equal to that of the coaming are to be fitted within the hopper in the same plane of coaming brackets. The brackets are to have a flange or face plate with a width 10 times their thickness.

Section 9 SPLIT HOPPER DREDGERS AND BARGES

14.9.1 General requirements

14.9.1.1 This Section applies to self-propelled or non-self-propelled steel split hopper barges and dredgers with a single deck. Those not covered in this Section are to comply with other applicable requirements of this Chapter.

14.9.1.2 A chain locker and a chain are usually to be provided on each half hull. For split hopper barges, only a single windlass may be provided on one of the half hulls. However, an appropriate guide gear is to be fitted so as to retract and release conveniently the chain on the other half hull.

Unmanned split hopper barges may be provided with only a single bower anchor. The length of the chain may be half the length as specified.

14.9.1.3 A rudder and a steering gear are to be provided on each half hull, and an automatic system for synchronized operation of both rudders is to be provided.

14.9.1.4 Where the hopper extends beyond 0.4L amidships, the thickness of shell plating and deck plating amidships is to be maintained for two frame spaces from hopper end bulkheads and gradually tapered in the fore and aft direction.

14.9.1.5 Shell plating and longitudinals in bilge areas are to be sufficiently strengthened.

14.9.1.6 In addition to the grades of steel required in 1.3.2 of Section 3, Chapter 1 of this PART, grade D steel is to be adopted for the plates bearing high stresses (reaction forces of hinges, hydraulic installations, load-bearing plates, etc.) and having a thickness greater than 20 mm, and grade E steel is recommended where the thickness of such plates is greater than 40 mm.

14.9.1.7 For solid floors in each half hull, B in the formula may be taken as the breadth of the half hull when it is calculated according to 2.5.4.1, Section 5, Chapter 2 of this PART.

14.9.2 Longitudinal strength

14.9.2.1 The midship section modulus of split hopper barges and dredgers of 65 m or over in length is to comply with the requirements of 14.2.2.1(1), Section 2 of this Chapter. The semi-sectional area of the midship strength deck of split hopper barges and dredgers less than 65 m in length is to comply with the requirements of 14.4.2.1, Section 4 of this Chapter.

14.9.2.2 For all split hopper barges and dredgers, the longitudinal strength of half hulls is to be checked for transit and dredging conditions, taking the influence of departure and arrival into account.

14.9.2.3 The longitudinal bending stress at any point of the cross section of half hulls within 0.4L amidships is to be obtained from the following formula, and not to be greater than 175/K, in N/mm², where K is material factor:

$$\sigma = \left(\frac{M_X}{I_X} Y - \frac{M_Y}{I_Y} X \right) \times 10^5 \quad \text{N/mm}^2$$

where: M_X, M_Y — bending moment about main axis of inertia, in kN · m, to be calculated in accordance with 14.9.2.4;

X, Y — coordinate value of the considered point in coordinate system GXY of main axis of inertia, in m, see Figure 14.9.2.3;

I_X, I_Y — moment of inertia about main axis of inertia, in cm⁴.

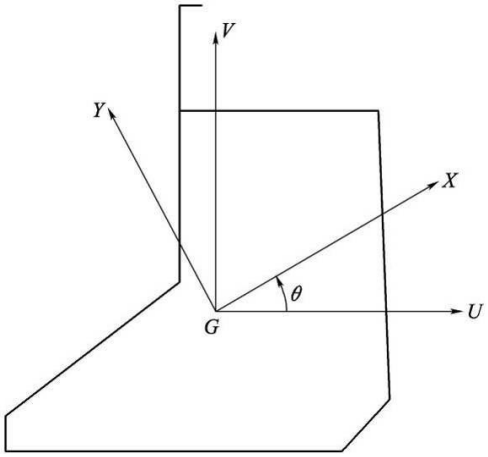


Figure 14.9.2.3

14.9.2.4 Bending moments M_X and M_Y about the main axis of inertia (GX, GY) of half hulls are to be obtained from the following formulae:

$$M_X = M_u \cos\theta + M_v \sin\theta \quad \text{kN} \cdot \text{m}$$
$$M_Y = -M_u \sin\theta + M_v \cos\theta \quad \text{kN} \cdot \text{m}$$

where: M_u, M_v — vertical bending moment and horizontal bending moment of section, in kN·m, respectively.

14.9.2.5 The vertical bending moment acting on half hulls in the midship area is to be obtained from the following formulae:

For transit condition: $M_u = 0.5(M_s + M_{wv})$ kN · m

For dredging condition: $M_u = 0.5(M_{sd} + M_{wv})$ kN · m

where:

M_s, M_{sd} — the maximum vertical still water bending moment under corresponding conditions, in kN · m, hogging moment being positive while sagging moment being negative;

M_{wv} — vertical wave bending moment, to be calculated in accordance with 2.2.3.1 of Section 2, Chapter 2 of this PART.

14.9.2.6 The horizontal bending moment acting on half hulls in the midship area is to be determined by the following formulae:

For transit condition: $M_v = M_{sH} + M_{wH}$ kN · m

For dredging condition: $M_v = M_{sHd} + M_{wH}$ kN · m

where: M_{wH} — horizontal wave bending moment, in kN · m, the positive and negative values being the same as those of M_{sH} or M_{sHd}, calculated in accordance with the following formula:

$M_{wH} = \pm 0.2\, L^{2.25}(d + 0.3B)C_b$ kN · m

where: L — length of ship, in m;

B — breadth of ship, in m;

d — draft under corresponding condition, in m;

C_b — block coefficient under corresponding condition;

M_{sH} — horizontal still water bending moment under transit condition, in kN · m, generally $M_{sH} = 0$;

M_{sHd} — horizontal still water bending moment under dredging condition, in kN · m. Where side edge is compressed, the horizontal still water bending moment is positive; where side edge is tensed, the horizontal still water bending moment is negative, calculated in accordance with the following formula:

$$M_{sHd} = \pm 0.125\, PL_p\,(2L_d - L_p) \quad \text{kN} \cdot \text{m}$$

where: L_p — length of hopper, in m, see Figure 14.9.2.6;

L_d — spacing of deck hinges, in m, see Figure 14.9.2.6;

P — horizontal load per unit length, in kN/m, calculated in accordance with the following formula:

$$P = 4.9\rho\,(h_1 - a)^2 - 5.0(d - a)^2$$

where: ρ — density of spoil, in t/m³, the same as that in 14.8.4.2;

h_1 — maximum height of spoil loaded above baseline, in m;

a — height of bottom sealing installation, in m;

d — draft under corresponding condition, in m.

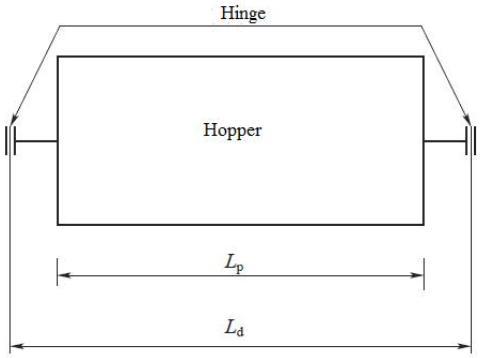

Figure 14.9.2.6

14.9.3 Deck hinges and hydraulic installations

14.9.3.1 The hydraulic installations connecting two half hulls is to have sufficient power so as to ensure that the half hulls can be opened and closed efficiently under any predicted sea conditions and that the half hulls will not be accidentally parted due to motion and vibration of the ship.

14.9.3.2 Local structures in way of connection to deck hinges and hydraulic installations are to be sufficiently strengthened, and are to efficiently transmit the load to the hull structure.

14.9.3.3 The scantlings of the members connecting deck hinges and hydraulic installations to two half hulls are to be determined by direct calculation. The load acting on such members is to be determined in accordance with the appropriate combination of predicted maximum static load and dynamic load under different design conditions.

14.9.3.4 The combined force F_h born by deck hinges under different design conditions is to be calculated in accordance with the following formula:

$$F_h = \sqrt{(F_{sh} + F_{dh})^2 + F_{dv}{}^2} \quad \text{kN}$$

where: F_{sh} — horizontal static force of deck hinges, in kN, to be calculated in accordance with 14.9.3.6(1) of this Section;

F_{dh} — horizontal dynamic force of deck hinges, in kN, to be calculated in accordance with 14.9.3.7 of this Section;

F_{dv} — vertical dynamic force of deck hinges, in kN, to be calculated in accordance with 14.9.3.7 of this Section.

14.9.3.5 The horizontal force F_r born by hydraulic installations under different design conditions is to be calculated in accordance with the following formula:

$$F_r = F_{sr} + F_{dr} \quad \text{kN}$$

where: F_{sr} — horizontal static force of hydraulic installations, in kN, to be calculated in accordance with 14.9.3.6(2) of this Section;

F_{dr} — horizontal dynamic force of hydraulic installations, in kN, to be calculated in accordance with 14.9.3.7 of this Section.

14.9.3.6 The horizontal static force of deck hinges and hydraulic installations is to be determined as follows:

(1) Horizontal static force F_{sh} of hinges:

$$F_{sh} = 0.5\left[F_w - F_s + 2(1-\frac{h_4}{h_5})F_{sr} + \frac{M}{h_5}\right] \quad \text{kN}$$

where: F_w — external still water pressure within hopper, in kN, to be calculated by the following formula:

$$F_w = 5.0(d-a)^2 L_p$$

F_s — horizontal pressure of spoil, in kN, to be calculated by the following formula:

$$F_s = 4.9\rho(h_1-a)^2 L_p$$

ρ, h_1, d, a, L_p — the same as those in 14.9.2.6;

F_{sr} — horizontal action force of hydraulic installations, in kN, to be determined according to (2) below;

M — moment, in kN · m, positive for opened half hull and negative for closed hull, determined by the following formula:

$$M = F_s h_2 - F_w h_3 + \Delta b_1 - W_l b_2 - W_s b_3$$

h_2 — vertical distance from horizontal pressure of spoil to hinge point, in m;

h_3 — vertical distance from external still water force to hinge point, in m;

h_4 — vertical distance from horizontal force of hydraulic installation to hinge point, in m;

h_5 — vertical distance from deck hinges to baseline, in m;

Δ — still water buoyancy of loaded half hull, in kN;

W_l — gravity of empty half hull, in kN;

W_s — gravity of half hull spoil, in kN;

b_1, b_2, b_3 — horizontal distance from Δ, W_l, W_s to hinge point respectively. See Figure 14.9.3.6.

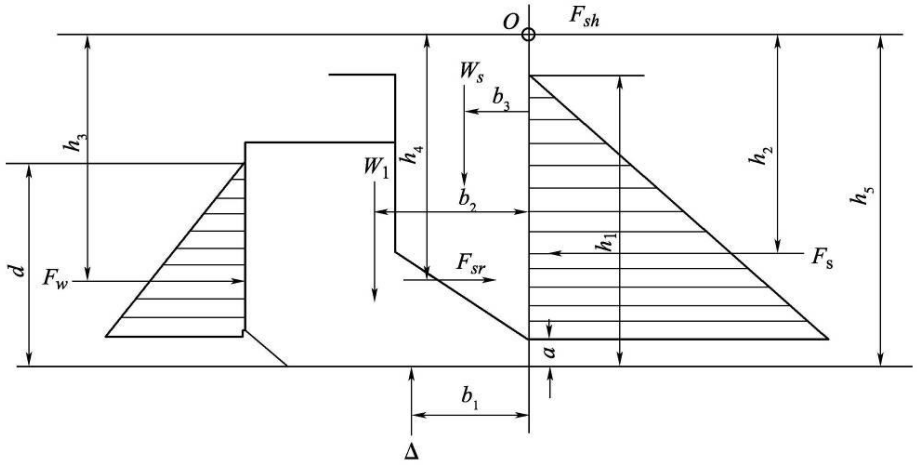

Figure 14.9.3.6

(2) The horizontal static force F_{sr} of hydraulic installations is equal to the pressure F_P acting on the end surface of the hydraulic cylinder piston, in kN, and its moment about the hinge point is to be equal to or more than the opening moment M so as to ensure the closure of two half hulls, i.e.:

$$F_{sr} = F_p \geq \frac{M}{2h_4} \quad \text{kN}$$

14.9.3.7 The dynamic load induced by the ship's motions in waves and acting on deck hinges and hydraulic installations is to be obtained from the dynamic calculation and statistic analysis in accordance with sea conditions for predicted operations. Where the significant wave height is no more than 3 m in sea conditions for predicted operations, the dynamic load may also be calculated in accordance with the following formulas:

Horizontal dynamic force of deck hinges: $F_{dh} = 0.28 f B^2 L$ kN

Vertical dynamic force of deck hinges : $F_{dv} = 0.055 f B^2 L^2 / d$ kN

where: L——ship length, in m;

B——ship width, in m;

d——distance between deck hinges, in m;

f——coefficient, taken f=1.5.

14.9.3.8 The formulae in 14.9.3.6 of this Section are only applicable to such condition where one deck hinge and one hydraulic installation are respectively fitted at both ends of the hopper. Where the number of

hinges and/or hydraulic installations are not the same, the calculation regarding systems of static and dynamic forces acting on the hull is required.

14.9.3.9 The scantlings of different parts of hinges are to be obtained as follows:

(1) The diameter d of the hinge pin is not to be less than that obtained from the following formulae:

$$d_1 = 54\sqrt{\frac{F}{R_{eH}}} \quad \text{mm}$$

$$d_2 = 13.2\sqrt[3]{\frac{F(2a - t_{2c})}{R_{eH}}} \quad \text{mm}$$

where: F — resultant force of hinges, in kN, to be calculated in accordance with 14.9.3.4 of this Section;

a — distance, in mm, between inner edges of eye plates at both sides or between inner edges of bushes of eye plates at both sides;

t_{2c} — length of contact, in mm, between centre eye plate or its bush and hinge pin;

R_{eH}— yield strength of hinge pin material, in N/mm².

(2) Eye plates are to comply with the following:

For centre eye plates: $b_{2c}t_{2c} + b_{1c}t_{1c} \geq \dfrac{2500\ F}{R_{eH}}$ mm²

For side eye plates: $b_{2s}t_{2s} + b_{1s}t_{1s} \geq \dfrac{1250\ F}{R_{eH}}$ mm²

where: F — the same as that in (1);

R_{eH}— yield strength of the material of eye plates, in N/mm²;

b_{1c}, b_{2c}, b_{1s}, b_{2s}, t_{1c}, t_{2c}, t_{1s}, t_{2s}, — see Figure 14.9.3.9.

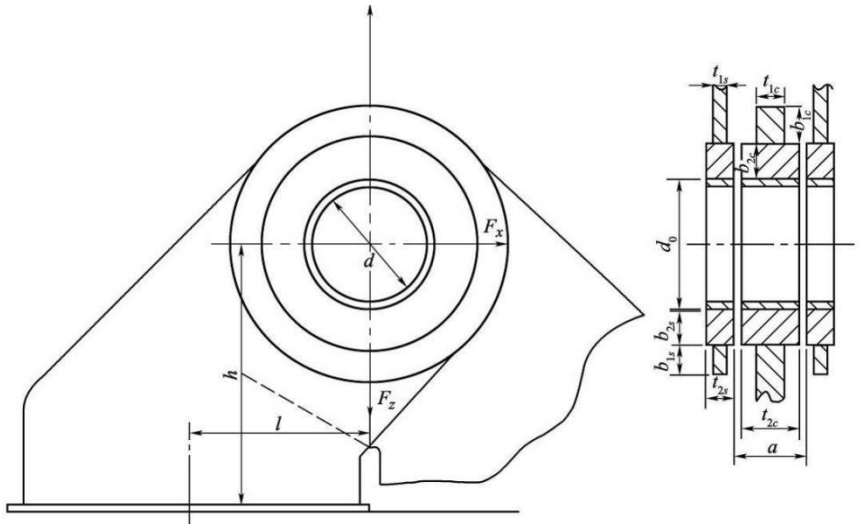

Figure 14.9.3.9

(3) The section of connection of centre eye plate and side eye plates to deck is to comply with the following formula:

$$\left(\frac{F_z}{A} + \frac{F_x h + F_z l}{W}\right) \times 10^3 \leq 0.6R_{eH} \quad \text{N/mm}^2$$

where: F_x — horizontal force of hinges, in kN, to be obtained from the following formula:

$$F_x = F_{sh} + F_{dh}$$

F_z — vertical force of hinges, in kN, to be obtained from the following formula:

$$F_z = F_{dv}$$

h — vertical distance from pintle centre to deck, in mm;

l — horizontal distance from centre of the hinge pin to sectional neutral axis, in mm;

A — sectional area, in mm²;

W — section modulus, in mm³;

R_{eH} — yield strength of the material of eye plates, in N/mm².

14.9.4 Hinges of deckhouses

14.9.4.1 The load acting on deckhouses is to be determined in accordance with the loading condition and movement of the ship.

14.9.4.2 The force born by deckhouses may be divided into three component forces of F_x, F_y and F_z, as shown in Figure 14.9.4.2, where OX is the central axis of rolling; F_x, F_y and F_z are acting at the centre of gravity of deckhouses.

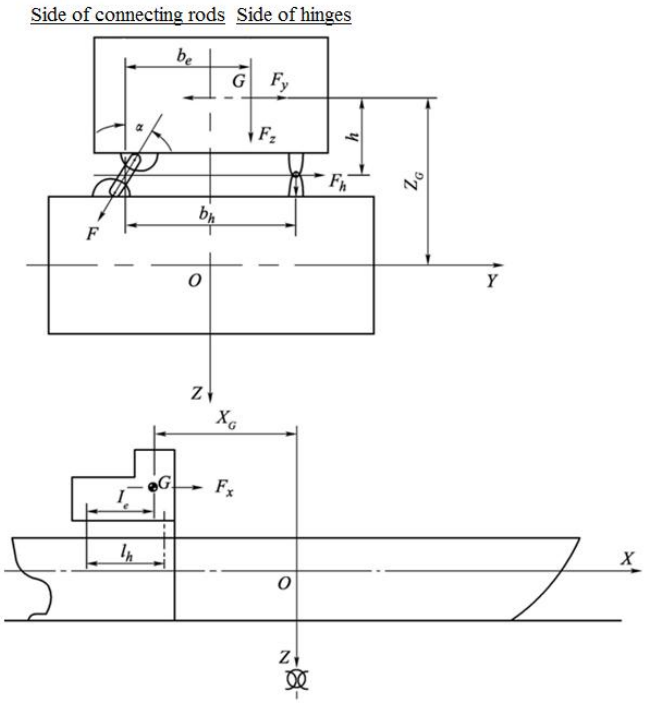

Figure 14.9.4.2

14.9.4.3 The distance from the central axis of rolling to baseline may be taken as the lesser of $\frac{D}{4}+\frac{d}{2}$ and $\frac{D}{2}$,where D and d are moulded depth and draft respectively, in m.

14.9.4.4 The longitudinal and transverse component forces F_x, F_y parallel to deck and the vertical component force F_z normal to deck are to be obtained from the following formulae:

$$F_x = Mg\,(0.19 + 0.026\,Z_G) \quad \text{kN}$$
$$F_y = Mg\,(0.5 + 0.039\,Z_G) \quad \text{kN}$$
$$F_z = Mg\,(1.17 + 0.026\,X_G) \quad \text{kN}$$

where: M — mass of deckhouses, in t;
Z_G — vertical distance from the center of gravity of deckhouses to OXY plane, in m;
X_G — horizontal distance from the center of gravity of deckhouses to OYZ plane, in m;
g — gravity acceleration, in m/s².

14.9.4.5 Where longitudinal load-bearing plates are provided to both half hulls, it may be assumed that the transverse component force F_y and the vertical component force F_z be born by hinges of deckhouses, and that the longitudinal component force F_x be born by longitudinal load-bearing plates. Otherwise, the hinges of deckhouses are also to bear the longitudinal component force F_x.

14.9.4.6 The forces born by the hinges of deckhouses are to be obtained by solving an equilibrium equation of force systems, according to the type and position of hinges and the actual position of the center of gravity of deckhouses.

14.9.4.7 Where the hinges of deckhouses are composed of two hinges and two end-hinged connecting rods, as shown in Figure 14.9.4.2, the forces born by the hinges are to be obtained by the following formulae:

For axial force F on connecting rods:

$$F = \frac{l_e}{l_h \cos\alpha}\left[F_y \frac{h}{b_h} + F_z\left(1 - \frac{b_e}{b_h}\right)\right] \quad \text{kN}$$

For transverse force F_h on hinges:

$$F_h = \frac{l_e}{l_h}\left[F_y(1 - \frac{h}{b_h}\tan\alpha) + F_z(1 - \frac{b_e}{b_h})\tan\alpha \right] \quad \text{kN}$$

For vertical force F_v on hinges:

$$F_v = \frac{l_e}{l_h}(F_y \frac{h}{b_h} + F_z \frac{b_e}{b_h}) \quad \text{kN}$$

For horizontal force F_c on each load-bearing plate:

$$F_c = \frac{1}{n_c} \quad F_x \quad \text{kN}$$

where: F_x, F_y, F_z — component forces acting on the center of gravity of deckhouses, in kN, to be determined in accordance with 14.9.4.4 of this Section;

α — the angle between the centreline of connecting rod and a vertical line, in degrees.;

l_e — longitudinal distance from the center of gravity of deckhouses to the farther hinge, in m;

b_e — transverse distance from the center of gravity of deckhouses to the vertical line at the centre of connecting rod, in m;

h — vertical distance from the center of gravity of deckhouses to the horizontal centreline of hinges;

b_h — transverse distance between hinge centre and connecting rod centre;

l_h — longitudinal distance between the centres of fore and aft hinges, in m;

n_c — number of load-bearing plates.

14.9.4.8 The scantlings of different parts of hinges of deckhouses are to be determined in accordance with 14.9.3.9 of this Section.

Section 10 MISCELLANEOUS

14.10.1 Bulwarks, guardrails and freeing ports

14.10.1.1 In open hopper dredgers and barges, bulwarks are not to be fitted in way of the hopper region, but guardrails or reliable anti-slip arrangements are to be provided. For dredgers fitted with bulwarks, freeing ports with adequate areas are to be fitted throughout the length of bulwarks.

14.10.2 Fenders

14.10.2.1 Dredgers and hopper barges are generally to be fitted with fenders along deck side throughout the ship's length, in accordance with their operation characteristics. Dredgers designed to work in conjunction with hopper barges are to be fitted also with fenders extending down to their lowest normal operating waterline. Vertical fenders, suitably spaced apart, are also to be fitted between such upper and lower fenders. The thickness of fenders may be taken as the thickness of the side shell plating at 0.4L amidships. Stiffeners are to be fitted inside the fenders.

14.10.3 Overflows

14.10.3.1 The cutting of overflow discharge trunk openings in the sheer strake is to be avoided wherever practicable. In ships over 65 m in length, hopper space overflow discharge trunk openings are not to be cut within 800 mm of the upper edge of the sheer strake. They are to have corner radii of not less than 150 mm, and suitable compensation is to be arranged. In no case is a discharge trunk to pierce the sheer strake in way of discontinuities such as breaks of superstructure.

14.10.4 Watertight trunk

14.10.4.1 Watertightness is to be kept around dredging pumps, within local range of holds in way of suction pipes and suction of trailing suction dredgers, penetrating through the hull.

14.10.5 Cofferdams

14.10.5.1 Ladder wells of bucket dredgers are to be isolated by cofferdams, the extent and widths of which are to be sufficient to contain any damage to the well side bulkheads or bottom shell plating that could result from the impact of large objects brought up in the dredge buckets. The cofferdams are to be accessible.

14.10.6 Supporting structures and seats of operating equipment

14.10.6.1 The local supporting structures connected with equipment members and foundations, as well as the seats of operating equipment are to have sufficient strength where necessary, the strength is to be checked.

14.10.6.2 Where direct calculation for check is applied, the model and strength criteria may refer to 3.7.2.5 and 3.7.2.6 of Chapter 3 of this PART. The loads are to be applied based on the working loads of equipment (e.g. working supporting loads of hydraulic winch), and the strength criteria may refer to Table 3.7.3.12 of Chapter 3 of this PART.

CHAPTER 15 SEMI-SUBMERSIBLE VESSELS

Section 1 GENERAL PROVISIONS

15.1.1 Application

15.1.1.1 This Chapter applies to the semi-submersible vessels intended for the carriage of ships, offshore installations or other massive goods.

15.1.1.2 Those not covered in this Chapter are to comply with the relevant requirements of Chapter 2 of this PART.

15.1.2 Definitions

15.1.2.1 **Semi-submersible vessel** means a ship, designed to load and unload cargoes, which is capable of being in a semi-submerged condition, with large open weather cargo deck and generally fitted with a forward or aft high superstructure or deckhouse or pontoon.

15.1.2.2 **Semi-submerged condition** means any condition in which the lifting cargo deck is submerged and reserve buoyancy is provided by the superstructure or deckhouse or pontoon only.

15.1.2.3 **Lifting cargo deck** means an open weather deck which is used for the carriage of goods and is submerged during loading/unloading operation.

15.1.2.4 **Maximum submerged depth** means a maximum draft to which the vessel is allowed to be submerged in semi-submerged operation conditions.

15.1.3 Class notation

15.1.3.1 Semi-submersible vessels complying with this Chapter are eligible to be assigned the class notation: Semi-Submersible Vessel.

15.1.4 Drawings and information

15.1.4.1 In addition to those stipulated in Section 1, Chapter 2 of this PART, the following drawings and information are to be submitted for reference:

(1) Hydrostatic curves, lifting and submersing curves;

(2) Operating manual.

Section 2 STRUCTURAL STRENGTH

15.2.1 General requirements

15.2.1.1 All ballast tanks are to be provided with air pipes, the diameters of which are to be in compliance with the relevant provisions of the Rules. A certain number of manholes are to be cut in suitable positions of longitudinal and transverse strength members of all ballast tanks so that each part of the tanks can be easily reached and in addition, ventilation will be achieved when the tanks are empty.

15.2.1.2 Where a non-self-propelled semi-submersible barge is to be towed, the towing strength is to be calculated and consideration is to be given to the arrangement of towing equipment and relevant structural strengthening.

15.2.1.3 The normal tensile steel or higher tensile steel used for the hull structure of semi-submersible vessels is to be in compliance with the relevant provisions of the Rules.

15.2.1.4 Where direct calculation or other commonly used empirical formulae are applied to determine the scantlings of each member, the relevant calculations together with assumptions used and descriptions are to be submitted to CCS for examination.

15.2.2 Longitudinal strength

15.2.2.1 The longitudinal strength is to meet the following requirements:

(1) The longitudinal strength is to meet the requirements of Chapter 2 of this PART under sea-going condition;

(2) For typical operation conditions of the semi-submersible vessel, longitudinal wave load is to be taken 50% of the value required in 2.2.3 of Chapter 2 of this PART;

(3) For loading and unloading conditions in harbor under mooring condition, longitudinal wave load is to be taken 20% of the value required in 2.2.3 of Chapter 2 of this PART;

(4) Possible or assumed most critical operation condition is also to be considered.

15.2.2.2 The minimum section modulus W_0 at deck and keel within at least 0.25L amidships of semi-submersible vessel is to meet the requirements of 2.2.5.1 of Chapter 2 of this PART.

15.2.2.3 The structural members considered in the calculation of the section modulus in respect to longitudinal strength are to be longitudinally continuous within 0.4L amidships. However, the crane trail is not to be considered in section modulus calculation.

15.2.3 Transverse strength

15.2.3.1 The transverse strength is to be checked for the typical transverse structures throughout the length of the vessel.

15.2.3.2 The conditions used for the transverse strength calculation are to cover the typical operation conditions of the semi-submersible vessel, including the assumed most critical operation condition to be expected.

15.2.3.3 The following loads are to be taken into account in the check of transverse strength:

(1) Self-weight of the semi-submersible vessel including supporting blocks;

(2) Maximum weight of objects to be carried;

(3) External hydrostatic pressure at a given draught;

(4) Internal hydrostatic pressure due to the level of evenly distributed ballast water associated with the draught as in (3) when lifting at maximum capacity.

15.2.3.4 The bending stresses are not to exceed 170/K, in N/mm², the shear stresses are not to exceed 95/K, in N/mm² and the combined stress at any point is not to exceed 180/K, in N/mm² (K being the material factor).

15.2.4 Local strength

15.2.4.1 The local strength under sea-going condition is to be calculated according to the relevant requirements of Section 13, Chapter 2 of this PART, and the strength under the lifting and submersing conditions (including the process of adjusting the ballast water level) is to be calculated in accordance with the requirements of this Section.

15.2.4.2 The thickness of boundary plating of ballast water tanks, oil tanks, fresh water tanks, bilge tanks, empty tanks, etc., is not to be less than the value obtained from the following formula:

$$t = t_0 + 2.5 \quad \text{mm, and not to be less than 7.5 mm}$$

where: $t_0 = 3.95 s\sqrt{\rho h K}$, t_0 is also to be multiplied by $1.1 - \frac{s}{2.5l}$ for $l/s<4$;

K — material factor;

s — spacing of stiffeners, in m;

ρ — density of liquid, in t/m^3, taken as not less than 1.025 for calculation;

h — calculated pressure head, in m, see Table 15.2.4.2, to be measured from the lower edge of plate;

l — span of stiffener, in m.

Table 15.2.4.2

Position of members	Pressure head h (m)
1. Boundary plating subjected to external hydrostatic pressure and internal hydrostatic pressure on both sides, such as shell plating of wing tanks, etc.	h_1: The maximum differential head in the position obtained from the lifting and submersing curve
2. Boundary of ballast water tank	h_2: The maximum differential head between two sides, not less than 3.5 m
3. Watertight boundary of empty hold	The greatest of the following heads: h_1: The maximum differential head in the position obtained from the lifting and submersing curve (if applicable) h_2: The maximum differential head between two sides, not less than 3.5 m (if applicable) h_3: The vertical distance from the considered point to the deepest submersing water level, not less than 3.5 m h_4: The differential head in the deepest submerging position obtained from the lifting and submerging curve
4. Ballast tank where compressed air is used to discharge water (if applicable)	The greatest of the following heads: h_1: The maximum differential head in the position obtained from the lifting and submersing curve (if applicable) h_2: The maximum differential head between two sides, not less than 3.5 m (if applicable) h_3: The vertical distance from the considered point to the deepest

Position of members	Pressure head h (m)
	submersing water level, not less than 3.5 m h_4: The differential head in the deepest submerging position obtained from the lifting and submerging curve h_5: Water head equivalent to the compressed air, not less than 3.5 m

15.2.4.3 For structural members subjected to lateral pressure on tank boundary plating as defined in 15.2.4.2 of this Section, such as bulkhead stiffeners, longitudinals, beams and ordinary frames, etc., the minimum section modulus W is not to be less than that obtained from the following formula:

$$W = 7shl^2K \qquad \text{cm}^3$$

where:

s — spacing of stiffeners, in m;
K — material factor;
l — span of stiffener, in m;
h — calculated pressure head, in m, see Table 15.2.4.2, to be taken the middle point of span.

15.2.4.4 The section modulus W of primary members (such as transverses, web frames, girders, etc.) is not to be less than:

$$W = 7bhl^2K \qquad \text{cm}^3$$

where:

b — breadth of supporting, in m, taken as the spacing of primary structural members;
K — material factor;
l — the considered span, in m;
h — calculated pressure head, in m, see Table 15.2.4.2, to be taken the middle point of span.

15.2.4.5 The thickness of non-watertight pillar bulkhead plating and the scantlings of stiffeners may be determined in accordance with the relevant requirements of the Rules, provided that the loading P is taken as the actual load supported by the pillars.

15.2.4.6 The sectional area, plate thickness and end reinforcement of cross ties are to be in accordance with the relevant requirements of Section 10, Chapter 2 of this PART, provided that the load P is taken as follows:

$$P = 9.8shl \qquad \text{kN}$$

where:

s — spacing of cross ties, in m;
h — maximum differential head, in m, to be measured from the lower edge of cross ties to the water level at maximum differential head;
l — vertical midspan-to-midspan distance between two girders immediately over and under the cross tie, in m.

CHAPTER 16 ORE CARRIERS

Section 1 GENERAL PROVISIONS

16.1.1 Application

16.1.1.1 This Chapter applies to the determination of structural arrangements and scantlings within the cargo region of self-propelled single deck ore carriers with machinery aft, having two longitudinal bulkheads in the cargo region and a double bottom throughout the centre hold, intended for the carriage of ore cargoes in the centre hold. A typical cross section of such ore carriers is shown in Figure 16.1.1.1. Ore carriers of 250 m and over in length and engaged in unrestricted service are to satisfy the requirements of CCS Rules for Structures of Ore Carriers.

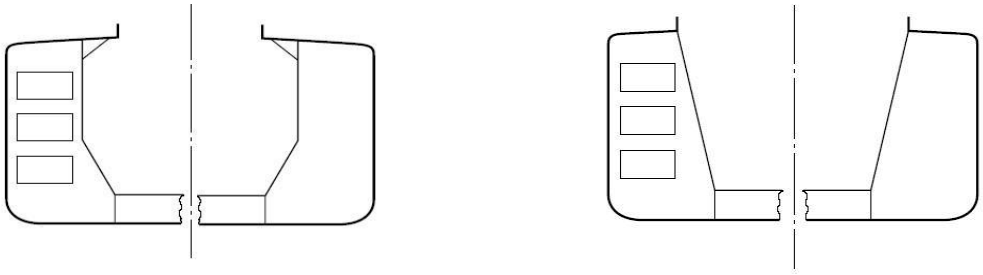

Figure 16.1.1.1

16.1.1.2 The fitting of a forecastle, the loading manual and loading instrument, cargo hold hatch covers and the flooding condition (where applicable) are to comply with the relevant requirements of Chapter 8 of this PART.

16.1.1.3 The strengthening for grabs is to comply with the relevant requirements of Section 23, Chapter 2 of this PART.

16.1.1.4 The requirements of Sections 3 and 4 of this Chapter are only applicable to the cargo hold area. Those not covered in this Chapter are to comply with the relevant requirements of Chapter 2 of this PART.

16.1.1.5 Ore carriers of 150 m and over in load line length and carrying solid bulk cargoes having a density of 1.0t/m^3 and above, as defined in SOLAS regulation XII/1, are to comply with the relevant requirements of Section 15, Chapter 8 of this PART.

16.1.2 Class notation

16.1.2.1 Ore carriers complying with the requirements of this Chapter are eligible to be assigned the class notation of Ore Carrier.

16.1.2.2 When requirements for loading and unloading in multiple ports have not been raised in the design of ore carriers in accordance with CCS Guidelines for Direct Strength Analysis of Hull Structure of Ore Carriers, No MP notation is to be assigned to indicate the limitation.

16.1.2.3 Ore carriers complying with the requirements of Section 5 of this Chapter are eligible to be assigned the class notation of **EL100**.

16.1.3 Arrangements and structural configuration

16.1.3.1 The bottom, and the strength deck outside the line of cargo hatchway openings, are to be framed longitudinally within the cargo region. Inside the line of openings, the strength deck is to be framed transversely.

16.1.3.2 The transverse watertight bulkheads in centre holds within the cargo region are to be located in the same plane with those in wing tanks as far as practicable, otherwise means are to be provided to ensure the continuity of transverse strength. However, the form of construction used for transverse watertight bulkheads in centre holds may be different from that used in wing tanks.

16.1.3.3 Strength frame rings, transverse watertight bulkheads and wash bulkheads, which may be fitted in wing tanks within the cargo region, are to be in the same plane with bottom floors of center holds.

16.1.3.4 Where necessary, the bottom between strength frame rings may be fitted with intermediate floors.

16.1.4 Direct strength calculation and fatigue strength assessment for hull structure

16.1.4.1 For ore carriers of 150 m and over in length, direct strength calculation in respect to primary members of the hull is to be carried out in accordance with the requirements of CCS Guidelines for Direct Strength Analysis of Hull Structure of Ore Carriers.

16.1.4.2 For ore carriers of 150 m and over in length, fatigue strength assessment in respect to the following locations within the cargo region is to be carried out in accordance with the requirements of CCS Guidelines for Fatigue Strength of Ship Structure:

(1) connections of longitudinals (bottom, side, deck and longitudinal bulkhead) to transverse web frames;

(2) connections of longitudinals (bottom, side, deck and longitudinal bulkhead) to transverse bulkheads;

(3) connections of longitudinal bulkheads to inner bottom plates;

(4) connections of inner bottom plates to lower stools;

(5) longitudinal bulkhead knuckles (if any).

16.1.4.3 For ore carriers of 250 m and over in length, special consideration is to be given to the effects of springing and whipping on hull structure fatigue strength. For detailed methods, see CCS Guidelines for Direct Calculation Assessment of Hull Structure Including Springing and Whipping.

Section 2 LONGITUDINAL STRENGTH

16.2.1 General requirements

16.2.1.1 The longitudinal strength is to comply with the requirements of Section 2, Chapter 2 of this PART.

16.2.1.2 Where the hold deck opening is large, the longitudinal strength in respect to a combination of bending moment and torque is to be checked in accordance with the requirements of Section 10, Chapter 7 of this PART, with the torque of cargo being taken as zero in general.

16.2.2 Ultimate strength of hull girder

16.2.2.1 The ultimate bending capacity of any transverse section of hull girder during navigation is to comply with the following requirements.

(1) The vertical ultimate bending capacity of hull girder is to comply with the following criteria:

$$\gamma_s \overline{M}_s + \gamma_w M_w \le \frac{M_U}{\gamma_R}$$

where: $\overline{M}_s$ — permissible still water bending moment, in kN·m;

M_w — wave bending moment, in kN·m;

M_U — vertical ultimate bending capacity of hull girder, in kN·m;

γ_s, γ_w, γ_R — partial safety factors, to be taken as:

$\gamma_s = 1.0$;

$\gamma_w = 1.2$;

$\gamma_R = \gamma_M \cdot \gamma_{DB}$;

where:

γ_M — partial safety factor, covering material, geometric and strength prediction uncertainties, to be taken as: $\gamma_M = 1.05$;

γ_{DB} — partial safety factor, covering the effect of double bottom bending, to be taken as:

$\gamma_{DB} = 1.10$ for hogging condition;

$\gamma_{DB} = 1.0$ for sagging condition.

(2) Curve M-χ

The ultimate bending capacities of a hull girder transverse section M_U, in hogging and sagging conditions, are defined as the maximum values of the curve of bending moment capacity M versus the curvature χ of the transverse section considered.

The curvature χ is positive for hogging condition and negative for sagging condition.

The curve M-χ is to be obtained by means of an incremental-iterative approach in accordance with Appendix 5, Chapter 7 of this PART.

(3) The hull girder transverse sections are constituted by the elements contributing to the hull girder longitudinal strength, and the standard diminution thickness given in Table 16.2.2.1 is to be deducted in calculation.

Standard thickness deduction **Table 16.2.2.1**

Position		Standard thickness deduction (mm)
Within 1.5 m below weather deck	One side connected to ballast water	1.0
	Two sides connected to ballast water	2.0
Elsewhere		1.0

16.2.2.2 For ore carriers of 250 m and over in length, special consideration is to be given to the effects of whipping on hull girder ultimate strength. For detailed methods, see CCS Guidelines for Direct Calculation Assessment of Hull Structure Including Springing and Whipping.

Section 3 HULL FRAMING

16.3.1 Double bottom

16.3.1.1 Unless provided otherwise in this Section, the structural arrangement and scantlings of double bottom are to comply with the relevant requirements of Section 6, Chapter 2 and Section 2, Chapter 8 of this PART. For ore carriers of 230 m and over in length, however, plate floors may be spaced not more than 2.8m apart.

16.3.1.2 The width and depth of the double bottom in way of centre holds are to comply with the strength requirements of this Chapter and in addition, the requirements for stability in loaded conditions.

16.3.1.3 Where the proposed depth of the double bottom exceeds 1.5 times the minimum depth required in Section 6 of Chapter 2 of this PART, the scantlings of the stiffeners on floors and girders are to be increased and the buckling of stiffeners, floors and girders is to be checked.

16.3.1.4 The scantlings of the stiffeners of watertight floors and girders in double bottom are to comply with the requirements for the stiffeners on bulkheads in deep tanks, and the stiffeners are to be bracketed at both ends.

16.3.1.5 Where single bottom is fitted in way of wing tanks, attention is to be given to a smooth transition of the inner bottom plating of the double bottom in way of center holds into single bottom wind tanks. The inner bottom plating is to be extended into the wing tank with a sufficient width and bracketed to the bulkhead or strength frame ring. The thickness t (mm) of bracket is not to be less than $5+0.025L$, where the L is the length of ship (to be taken not greater than 300m for calculation), and the thickness of bracket is to be given a smooth transition of inner bottom plating.

16.3.1.6 Where single bottom is fitted in way of wing tanks and if intermediate floors are fitted only in way of centre hold bottom between strength frame rings, attention is to be given to a smooth transition of the floors into wind tanks, and vertical brackets are to be fitted in corresponding positions within wing tanks. Such brackets are, in general, to extend transversely over a sufficient width and vertically to a sufficient height above the extension of inner bottom plating in wing tanks. The thickness of the brackets may be the same as that of plate floors. The thickness of brackets may be directly calculated for ore carriers with the length of 150m and above, but not less than the minimum thickness of solid floors required in 16.3.1.8.

16.3.1.7 Where the double bottom is interconnected with wing tanks or centre holds are used as storm ballast tanks, the scantlings of which are also to comply with the requirements in Section 13, Chapter 2 of this PART for deep tanks.

16.3.1.8 The minimum thickness of solid floors is not to be less than the value calculated by the following formula:

$$t_{\min} = \max\left(0.6\sqrt{L} + 2.5, 12\right) \qquad \text{mm}$$

where: L – length of ship, in m, to be taken not greater than 300 m for calculation.

16.3.2 Single bottom

16.3.2.1 The section modulus W of bottom longitudinals is not to be less than that obtained by the following formula:

$$W = 11.5sdl^2K \qquad \text{cm}^3$$

where: s — spacing of longitudinals, in m;
d — draught, in m;
l — span of longitudinal, in m;
K — material factor.

16.3.2.2 The scantlings of bilge longitudinals are to be graduated between those required for the bottom

and lowest side longitudinals.

16.3.2.3 Floors are to be spaced not more than 3.6 m apart. The section modulus W and the net floor area A of floors at the span point are not to be less than those obtained as follows, but not greater than those of corresponding centre hold floors:

$$W = 4.59\ SDl^2K \text{ cm}^3$$
$$A = 0.56\ SDlK \quad \text{cm}^2$$

where: S — spacing of floors, in m;
D — moulded depth, in m;
l — span of floor, in m;
K — material factor.

16.3.2.4 The spacing and scantlings of bottom girders are to be determined by direct calculation.

16.3.3 Deck framing

16.3.3.1 The deck framing is to comply with the relevant requirements of Section 8, Chapter 2 of this PART.

16.3.3.2 The buckling of deck structure between hatchways is to be checked.

16.3.4 Side framing

16.3.4.1 The ship's sides are normally longitudinally framed, and the side longitudinals within $0.1D$ from bottom and deck are to continuously pass through transverse bulkheads. The section modulus W of side longitudinals is, in addition to satisfying relevant requirements of 2.7.5, Chapter 2 of this PART, not to be less than that obtained by the following formula:

$$W = 7.2s(h+1.2)l^2K \qquad \text{cm}^3$$

where: s — spacing of longitudinals, in m;
h — vertical distance measured from the longitudinal under consideration to deck line at side amidships, in m, but not less than 2.5 m;
l — span of longitudinal, in m;
K — material factor.

16.3.4.2 Web frames are to be fitted in the plane of plate floors of longitudinally framed bottom.

16.3.4.3 The section modulus W of web frames is not to be less than that obtained by the following formula:

$$W = CS(h + 1.2)l^2K \quad \text{cm}^3$$

where: S — spacing of web frames, in m;
h — vertical distance measured from the mid-span of web frame to deck line at side, in m;
l — span of web frame, in m;
C — coefficient: $C = 11$, without horizontal strut; $C = 3.2$, with 1 horizontal strut; $C = 3$, with 2 horizontal struts;
K — material factor.

16.3.4.4 The net web area A of web frames is not to be less than that obtained by the following formula:

$$A = C_1S(h + 1.2)lK \quad \text{cm}^2$$

where: S — spacing of web frames, in m;
h — vertical distance measured from the mid-span of web frame to deck line at side, in m;
l — span of web frame, in m;
C_1 — coefficient: $C_1 = 0.5$ at section of span points and 0.25 at other sections, with 1 horizontal strut; $C_1 = 0.66$ at section of span points and 0.33 at other sections, with 2 horizontal struts;
K — material factor.

16.3.4.5 The dimensions of web frames may be directly calculated for ore carriers with the length of 150 m and above.

16.3.5 Strength frame rings in wing tanks

16.3.5.1 The strength frame ring in wing tanks is composed of web beams, web frames, plate floors, vertical girders on the longitudinal bulkhead and cross ties.

16.3.5.2 The spacing S of strength frame rings is not to be more than that obtained by the following formula:

$$S = 0.006L + 3.2 \quad \text{m, but not greater than 5.6 m}$$

where: L — length of ship, in m.

16.3.5.3 Cross ties are to comply with the relevant requirements of Section 8, Chapter 5 of this PART. The dimensions of cross ties may be directly calculated for ore carriers with the length of 150m and above.

16.3.5.4 The cross ties are to be subject to integral buckling check as beams.

16.3.5.5 The minimum thickness of webs of strength frame rings in wing tanks is not to be less than the value calculated by the following formula:

$$t_{\min} = \max\left(0.6\sqrt{L} + 2.5, 12\right) \qquad \text{mm}$$

where: L – length of ship, in m, to be taken not greater than 300m for calculation.

16.3.6 Cargo hold boundary

16.3.6.1 Cargo hold boundary means longitudinal bulkhead, corrugated transverse bulkhead as well as upper and lower stool (if any), plane transverse bulkhead, upper deck and hatch coaming in the cargo hold (except for inner bottom) which are in contact with cargo.

16.3.6.2 Thickness t of cargo hold boundary plate is not to be less than the value obtained from the following formula:

$$t = 4.65 C_1 s \sqrt{\frac{K_C H K}{\gamma}} \qquad \text{mm}$$

where: s — length of shorter side of plate panel, in m;

γ — loading rate, in m^3/t, not to be more than 0.833;

H — vertical distance measured from lower edge of panel to deck in way of midship side, in m;

$C_1 = 1.2 - \frac{s}{2l}$, where l is length of longer side of plate panel, C_1 is to be taken as 1 for $C_1 > 1$;

K_C — cargo pressure coefficient, to be taken as:

$Kc = \cos^2\alpha + (1 - \sin\psi)\sin^2\alpha$ for transverse bulkhead and longitudinal bulkhead, lower stool, vertical upper stool and hatch coaming;

$Kc = 0$ for upper deck and inclined upper stool;

where: α — included angle between considered plate and horizontal plane, in degree;

Ψ — angle of repose assumed for cargo in bulk, in degree, to be taken as 35° for carriage of ore;

K — material factor.

16.3.6.3 Section modulus W of cargo hold boundary stiffener is not to be less than the value obtained from the following formula:

$$W = \frac{8.5}{\gamma} K_C H s l^2 K \qquad \text{cm}^3$$

where: γ and K_C — the same as those in 16.3.6.2;

l — span of stiffener, in m;

s — spacing of stiffeners, in m;

H — vertical distance measured from the midpoint of span of stiffener to deck in way of midship side, in m;

K — material factor.

16.3.7 Web stiffeners of non-watertight primary members within cargo hold area

16.3.7.1 Where the dimensions of web stiffeners of non-watertight primary members within cargo hold area are calculated, the thickness deduction listed in 16.3.7.1 is to be reduced.

Thickness Deduction Table 16.3.7.1

Location	Thickness deduction (mm)
Both sides within ballast tanks	2.0
Elsewhere	1.0

16.3.7.2 Net thickness of web stiffeners is to satisfy the following criteria:

(1) Minimum net thickness of stiffener web plate

The net thickness of stiffener web plate is not to be less than 3.0+0.015L, where L is ship length (L need not be taken greater than 300 m during calculation).

(2) Stiffener web plate

$$t_w \geq \frac{h_w}{C_w}\sqrt{\frac{R_{eH}}{235}}$$

(3) Flange

$$t_f \geq \frac{b_{f-out}}{C_f}\sqrt{\frac{R_{eH}}{235}}$$

where: C_w, C_f — slenderness coefficient given in Table 16.3.7.2;
$b_{f\text{-}out}$ — maximum distance, in mm, from mid thickness of the web to the flange-edge, as shown in Figure 16.3.7.2;
h_w — depth of stiffener web, in mm, as shown in Figure 16.3.7.2;
t_f — net flange thickness, in mm;
t_w — net thickness of plate, in mm;
R_{eH} — Specified minimum yield stress of the plate material, in N/mm^2.

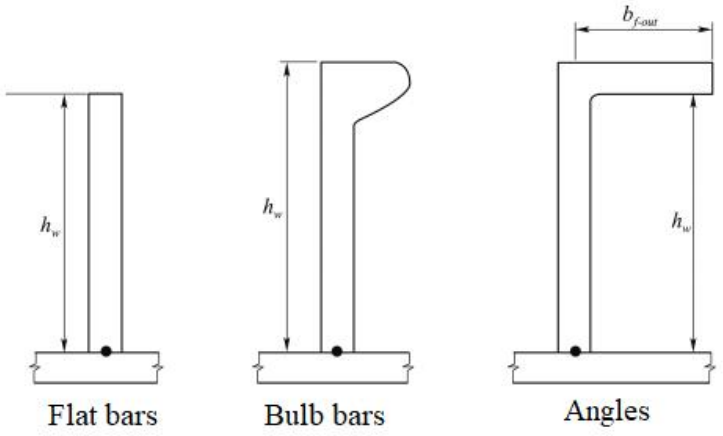

Figure 16.3.7.2 Stiffener Scantling Parameters

Slenderness Coefficients Table 16.3.7.2

Type of stiffener	C_w	C_f
Angle bars	75	12
Bulb bars	45	-
Flat bars	22	-

16.3.7.3 The total flange breadth b_f, in mm, for angle and T-bars is to satisfy the following criterion:

$$b_f \geqslant 0.25h_w$$

where: h_w — as defined in 16.3.7.2;

16.3.7.4 Bending stiffness of web stiffeners

The net moment of inertia, in cm^4, of web stiffener, I_{st}, fitted on non-watertight primary members within cargo hold area onboard ore carriers, with effective attached plate, s_{eff}, is not to be less than the minimum moment of inertia defined in Table 16.3.7.4, the breadth of effective attached plate s_{eff}, is to be calculated by the following formula:

$$s_{eff} = 0.8s \quad \text{mm}$$

where: s — breadth of web plate panel, in mm, to be taken as the spacing of web stiffeners.

Stiffness Criteria for Web Stiffeners Table 16.3.7.4

Stiffener arrangement		Minimum moment of inertia of web stiffeners, in cm^4
A	Web stiffeners fitted along the primary member span 	$I_{st} \geq Cl^2 A_{eff} \frac{R_{eH}}{235}$

Stiffener arrangement		Minimum moment of inertia of web stiffeners, in cm^4
B	Web stiffeners fitted normal to the primary member span 	$I_{st} \geq 1.14 l s^2 t_w \left(2.5 \frac{1000l}{s} - 2 \frac{s}{1000l} \right) \frac{R_{eH}}{235} \cdot 10^{-5}$

where: C — slenderness coefficient to be taken as:
$C = 1.43$ for longitudinal stiffeners including sniped stiffeners;
$C = 0.72$ for other stiffeners.
l — length of web stiffener, in m.
(1) For web stiffeners welded to local supporting members, the length is to be measured between the flanges of the local supporting members.
(2) For sniped web stiffeners, the length is to be measured between the lateral supports, e.g. the total distance between the flanges of the primary member as shown for stiffener arrangement B.
A_{eff} — net section area of web stiffeners, including attached plate with effective width assumed to be 80% of stiffener spacing s, in cm^2.
t_w — net web thickness of the primary member, in mm.
R_{eH} — specified minimum yield stress of the material of the web plate of the primary member, in N/mm^2.

Section 4 BULKHEADS

16.4.1 Transverse watertight bulkheads

16.4.1.1 Transverse watertight bulkheads are to be fitted with plate floors at bottom.

16.4.1.2 The scantlings of upper and lower stools of transverse watertight bulkheads are, if fitted, to comply with the requirements of this Section and in addition, the relevant requirements of Section 12, Chapter 2 of this PART.

16.4.1.3 The transverse bulkheads forming the boundary of ballast holds are to comply with the requirements of Section 13, Chapter 2 of this PART for deep tank bulkheads.

16.4.1.4 The thickness of the lowest strake of transverse watertight bulkheads is to be not less than that of inner bottom plating defined in 2.22.3.4 and 2.23.3.1 of Chapter 2 in this PART and is to be gradually tapered upwards.

16.4.2 Longitudinal watertight bulkheads

16.4.2.1 Longitudinal watertight bulkheads are to be plane, and framed longitudinally in general.

16.4.2.2 The longitudinal bulkheads are to be fitted with continuous bottom girders.

16.4.2.3 The scantlings of the longitudinal bulkheads are to comply with the requirements of this Section and in addition, the relevant requirements of Section 12, Chapter 2 of this PART.

16.4.2.4 The thickness of the longitudinal bulkhead plating in way of the knuckle is to be appropriately increased and the knuckle may be strengthened by horizontal girders to improve resistance to transverse compressive buckling stresses. The scantlings of the horizontal girders are to be determined by direct calculation.

16.4.2.5 Primary members are to be fitted at any vertical knuckle of longitudinal bulkhead. Distance between knuckle and primary members is not to be greater than 70 mm. Where the knuckle is not vertical, it is to be strengthened appropriately with normal stiffeners in the same line with the knuckle or other equivalent measures are to be taken.

16.4.2.6 Bulkhead plating

(1) The thickness t of bulkhead plating is not to be less than that obtained by the following formula:

$$t = 4s\sqrt{hK} + 2.5 \quad \text{mm}$$

where: s — spacing of stiffeners, in m;
h — vertical distance, in m, measured from lower edge of strake to tank top on the centreline, but not less than $0.4D$;
K — material factor.

(2) The thickness t of bulkhead plating within $0.1D$ from deck is not to be less than that obtained by the

following formula:

$$t = 4.2s\sqrt{DK} + 2.5 \quad \text{mm}$$

where: s — spacing of stiffeners, in m;
D — moulded depth, in m;
K — material factor.

(3) The thickness t of bulkhead plating is to additionally comply with the following:

$$t \geq as/27D \quad \text{mm}$$

where: s — spacing of stiffeners, in m;
a — vertical distance, in m, measured from $D/2$ to the centre of panel;
D — moulded depth, in m.

(4) The thickness of the lowest strake of the longitudinal bulkheads is not to be less than that of adjacent inner bottom plating defined in 2.22.3.4 and 2.23.3.1 of Chapter 2 in this PART and is to be gradually tapered to the thickness of longitudinal bulkhead plating.

(5) The thickness of longitudinal bulkhead plating within 0.1D from deck need not exceed the sheer strake thickness with the same spacing of frames.

16.4.2.7 Vertical webs

(1) The vertical webs on longitudinal bulkheads are to be fitted within wing tanks, and the dimensions of the vertical webs are to be calculated according to 16.3.4.3 of this Chapter, and direct strength calculation may be carried out for ore carriers with the length of 150m and above.

(2) The brackets at both ends of the vertical web are to comply with the relevant requirements of 1.2.7 of Chapter 1 of this PART.

(3) Buckling-restrained stiffeners are generally to be fitted onthe vertical web plating.

16.4.2.8 Horizontal stiffeners

(1) The section modulus W of horizontal stiffeners is not to be less than that obtained by the following formula:

$$W = 7.2s(h+1.2)l^2K \quad \text{cm}^3$$

where: s — spacing of horizontal stiffeners, in m;
h — vertical distance, in m, measured from horizontal stiffener to tank top on the centreline, but not less than 2.5 m;
l — span of horizontal stiffener, in m;
K — material factor.

(2) Horizontal stiffeners are to continuously pass through transverse bulkheads within 0.1D from deck and inner bottom.

16.4.3 Wash bulkheads

16.4.3.1 Where necessary, plane perforated wash bulkheads are to be fitted in wing tanks.

16.4.3.2 Wash bulkheads are to comply with the relevant requirements of Section 11, Chapter 5 of this PART.

Section 5 EASY LOADING REQUIREMENTS

16.5.1 General requirements

16.5.1.1 This Section applies to ore carriers having a single hold being capable of loading 100% (easy loading) capacity in one step for all cargo holds.

16.5.1.2 Average loading rate during easy loading is not to be more than the provisions in Table 16.5.1.2. Higher average loading rate is to be specially considered.

Average loading rate **Table 16.5.1.2**

Deadweight tonnage (t)	Average loading rate (t/h)
220,000 ~ 250,000	14,000
> 250,000	16,000

16.5.2 Class notation

16.5.2.1 Ore carriers complying with the provisions of this Section are to be assigned class notation EL100.

16.5.3 Hull structure strength

16.5.3.1 In the whole process of easy loading, actual still water bending moment and still water shearing force of hull girder are not to exceed permissible still water bending moment and permissible still water shearing force in harbor condition.
16.5.3.2 In the whole process of easy loading, it is to be ensured that double bottom and transverse bulkhead have sufficient local strength, and direct calculation of structural strength is to be carried out in accordance with CCS Guidelines for Direct Strength Analysis of Hull Structure of Ore Carriers.

16.5.4 Equipment provision and requirements
16.5.4.1 If ballast adjustment is required to control that actual still water bending moment and still water shearing force of hull girder do not exceed permissible still water bending moment and still water shearing force in harbor condition, requirements of 16.5.4.2 and 16.5.4.3 are to be complied with.
16.5.4.2 The ballast system is to be able to match the requirements of mean loading rate in 16.5.1.2, including ballast tank arrangement, capacity of ballast pump and arrangement of ballast piping system.
16.5.4.3 The ship is to be provided with tank (e.g. ballast tank, fuel oil tank, etc.) remote control sounder and ship draught reading system, which are synchronous with loading instrument on board. It is not necessary to consider fuel oil tanks without level change during loading.

16.5.5 Requirements of easy loading manual
16.5.5.1 Easy loading manual which is approved by CCS is to be provided on board or may be included in other approved loading manual.
16.5.5.2 Easy loading sequence is to include operation sequence of each step of loading from the beginning to the end as well as synchronous ballast adjustment, so as to ensure that the requirements of 16.5.3.1 are complied with during loading (including each cargo hold from empty load to full load).
16.5.5.3 Easy loading manual is at least to include following:
(1) loading capacity in each hold for each step;
(2) ballast water adjustment in each ballast tank for each step;
(3) maximum still water bending moment and shearing force at the end of each step;
(4) ship’s draught and trim at the end of each step.

CHAPTER 17 LAUNCHING WORK BARGES

Section 1 GENERAL PROVISIONS

17.1.1 General requirements

17.1.1.1 This Chapter applies to non-self-propelled work barges dedicated to launching ships or offshore installations under construction, or moving from water to shore, within shipyard and/or port waters, and short-distance movement within the above-mentioned waters.

17.1.1.2 For those not covered in this Chapter, the relevant requirements of Chapter 2 of this PART and of CCS Rules for Classification of Floating Docks are to be complied with.

17.1.2 Plans and documents

17.1.2.1 The following plans and documents are to be submitted for information in addition to those as specified in Section 1, Chapter 2 of this PART:

(1) Hydrostatic curves, lifting and submersing curves;

(2) Operating manual.

17.1.3 Definitions

17.1.3.1 **Launching work barge** means a dedicated barge used for launching operation, having larger open pontoon deck, bow and/or stern, and higher superstructure or deck house on both sides. The superstructure on both sides may be arranged discontinuously along the longitudinal direction, and some of the superstructure or deck house may be removed where necessary. Special crane rails and trolleys are to be provided on the pontoon deck. Where the objects intended for moving is being moved from shore to water or from water to shore, the pontoon deck is to be maintained on the same level as the shore land, then the object is to be moved by the trolley. The in-water loading/unloading operation may be carried out by the ship's lifting and submerging. Cranes are not provided onboard. Figure 17.1.3.1 shows a diagram of typical launching work barge.

17.1.3.2 **Semi-submerged condition** means any condition in which the pontoon deck is submerged and reserve buoyancy is provided by the superstructure or deckhouse or pontoon only.

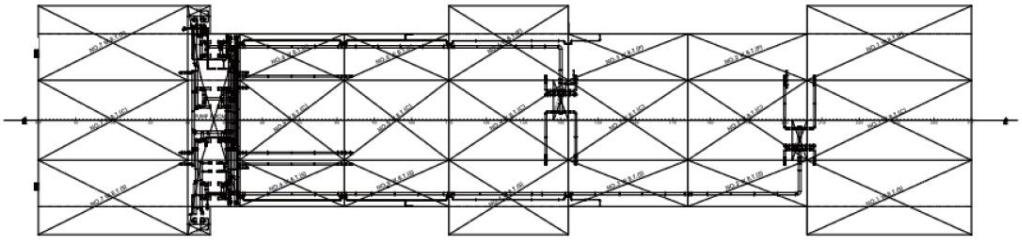
17.1.3.3 **Pontoon deck** means an open weather deck which is used for the carriage of objects intended for moving and is submerged during loading/unloading operation, also referred to as lifting cargo deck.

17.1.3.4 **Maximum submerged depth** means a maximum draft to which the vessel is allowed to be submerged in semi-submerged operating conditions.

17.1.3.5 **Length of pontoon L_D (m)** means a distance from the aft end of the aftermost pontoon to the fore end of the forward pontoon of a launching work barge, but is exclusive of non-integral end platforms or swing bridges.

17.1.3.6 **Safety deck** means a deck extending over superstructure or deck house on both sides, and located below the top deck and above the ballast tank, which is watertight at the positions of ballast deck.

Longitudinal section at port



Plane of ballast tank

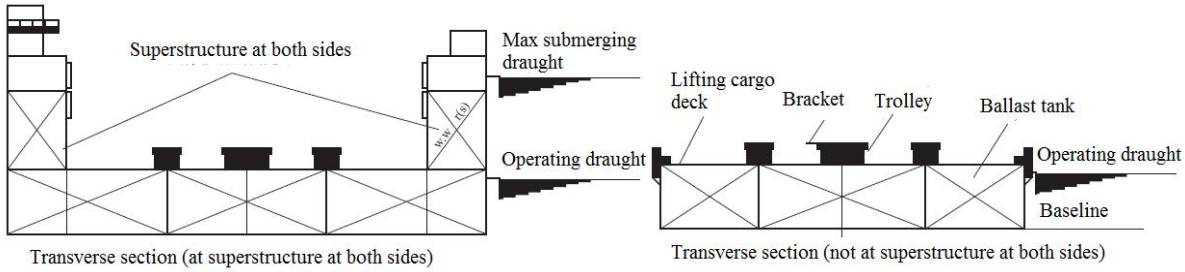


Figure 17.1.3.1 Diagram of a Certain Typical Launching Work Barge

17.1.4 Class notation

17.1.4.1 The class notation "Launching Work Barge" is to be assigned to a barge which complies with the provisions of this Chapter.

Section 2 LONGITUDINAL STRENGTH

17.2.1 General requirements

17.2.1.1 Unless otherwise specified in this Section, the longitudinal strength is to comply with the requirements of Section 2, Chapter 2 of this PART.

17.2.1.2 The longitudinal strength is to include the terminal operating conditions and harbor operating conditions, if any.

17.2.1.3 Structural members of the hull girder based on section modulus are to be maintained longitudinally continuous within $0.4L_D$ amidships, excluding the crane rails.

17.2.2 Loads

The loads of longitudinal strength are specified as follows:

(1) The buoyancy is to be assumed to distribute homogeneously along the ship's length.

(2) The weight of objects and distribution are to be assumed according to the following design conditions:

① In the case of the objects intended for moving being placed onboard: it is assumed that the total weight of objects based on designed lifting capacity is distributed to trolleys of the launching work barge according to the actual condition, then transferred to the pontoon deck below through trolleys. In calculation, the total capacity of trolleys is to be taken as the total weight of objects intended for moving, otherwise, disequilibrium of the buoyancy and weight will be caused on the general force system. In addition, the maximum load capacity of trolleys is not to be less than the distributed load on a single trolley.

② In the case of the objects being moved onboard: it is assumed that the weight distribution of object intended for moving is as the same as that in ①, and only partial length of the object is moved inboard, the bending strength and shearing strength in way of the weak section are to be checked according to the actual ballast water condition. In this case, the draught of work barge is to be based on the sea surface elevation due to tide variation, the partial weight of the object moved inboard, the weight of work barge and the hydrostatic equilibrium of buoyancy.

(3) The still water bending moment and shear force under all actual operating conditions (which are to include the typical ones of most unfavorable conditions for objects to be launched or moved to shore, and in the operation of lifting/submerging objects, etc.) are to be taken into account.

17.2.3 Longitudinal strength check

17.2.3.1 The longitudinal strength is to be checked in accordance with the requirements of Section 2, Chapter 2 of this PART, and complying with the following requirements:

(1) For terminal operating conditions, the allowable bending stress is to be taken $137/K$, in N/mm^2; the shear stress is to be taken $95/K$, in N/mm^2 (K being the material factor, but not less than 0.72).

(2) For harbor operating conditions, the allowable bending stress is to be taken $175/K$, in N/mm^2; the shear stress is to be taken $110/K$, in N/mm^2 (K being the material factor, but not less than 0.72).

(3) The minimum section modulus W_0 amidships is not required.

(4) For terminal operating conditions of launching work barges, the wave loads are not to be included.

(5) For harbor operating conditions of launched work barges, the wave loads are to be taken 50% of that as required in Section 2, Chapter 2 of this PART.

Section 3 TRANSVERSE STRENGTH

17.3.1 General requirements

17.3.1.1 The transverse strength is to be calculated for typical transverse structures throughout the length of ship in accordance with the requirements of this Section. In addition to the yield strength calculation, the plate panels and transverses subject to transverse bending moment and shear stresses are to be checked for buckling according to the requirements of 2.2.7 in Section 2, Chapter 2 of this PART.

17.3.1.2 The transverse strength of fore and aft ends of the pontoon is not to be lower than that as required for the mid-portion of the pontoon.

17.3.2 Loads

17.3.2.1 The primary transverse strength members of launching work barges, throughout its length L_D, is to be suitable for the sum of the following load components (normally, the weight of the rail, trolley and its facilities, as well as the hydrostatic pressure effect on horizontal action may be neglected):

(1) self-weight of the launching work barge (including the weight of superstructure or deck house on both sides and pontoon);

(2) weight of object intended for moving, see 17.2.2 of this Section;

(3) external hydrostatic pressure due to a given draught. The most severe condition normally occurs when the draught is equal to the depth to the top of the trolley bracket (i.e. the bottom of the object intended for moving is just lifted above the water surface);

(4) internal hydrostatic pressure due to the level of evenly distributed ballast associated with the draught as in (3) above;

(5) hydrostatic pressure of the outside of pontoon's bottom;

(6) reaction forces (if any) on superstructure or deck house longitudinal bulkheads on both sides required for achieving equilibrium of the buoyancy and weight on the section under consideration. Such reaction forces applied on internal and external longitudinal bulkheads on both sides of superstructure or deck house may be assumed as equal.

17.3.3 Calculation model

17.3.3.1 The transverse bending strength and shear strength of some typical longitudinal sections taken over the transverse length (where symmetrical, only half the breadth may be taken) of the pontoon are to be checked. The spacing of transverse bulkheads is to be taken as the longitudinal length of the section calculated, and the weak points of transverse strength are to be included in the check point of the section.

17.3.3.2 When lifting at maximum capacity with a launching work barge length less than that of the pontoon, the sections clear of the ship will experience transverse hogging due to the combination of loads in 17.3.2.1(1), (3), (4), (5) and (6). Hence, such condition is to be checked as appropriate for the sections concerned. The most severe condition will usually occur when the ballast depth is at a minimum (i.e. residual water only).

17.3.4 Transverse strength check

17.3.4.1 The permissible stress of transverse primary members are to be as follows:

permissible normal stress $[\sigma] = 170/K$ N/mm^2;

permissible shear stress $[\tau] = 95/K$ N/mm^2;

permissible equivalent stress $[\sigma_e] = \sqrt{\sigma^2 + 3\tau^2} = 180/K$ N/mm^2.

17.3.4.2 Special care is to be taken to the maintenance of transverse strength standard (not to be lower than that of 17.3.4.1) in end sections of launching work barges with swim ends where the pontoon depth is reduced.

Section 4 LOCAL STRENGTH

17.4.1 General requirements

17.4.1.1 Scantlings of the hull structural members are not to be less than that as specified in this Section, and to be adequate to meet the requirements for longitudinal strength, transverse strength and direct calculation.

17.4.1.2 Primary structural members, such as longitudinals, beams and ordinary frames of pontoons are to be maintained continuous, and transitional brackets are to be fitted where it is interrupted.

17.4.2 Tank boundary plating

17.4.2.1 The thickness of boundary plating of ballast water tanks, oil tanks, fresh water tanks, bilge tanks, empty tanks, etc., is not to be less than that obtained from the following formula:

$$t = t_0 + 2.5 \quad \text{mm}$$

where: $t_0 = 3.95s\sqrt{\rho hK}$ mm, when l/s is less than 4, the thickness obtained from the above formula is to be multiplied by the factor: $1.1 - \frac{s}{2.5l}$;

s — spacing of stiffeners, in m;

K — material factor;

h — calculated head, in m, taken as in Table 17.4.2.1;

l — span of stiffener, in m.

Table 17.4.2.1

Location of members	Calculated head h (m)	Remarks
1. Boundary plating subjected to external hydrostatic pressure and internal hydrostatic pressure on both sides, such as longitudinal bulkhead plating of watertight ballast tank of superstructure, shell plating of pontoon, etc.	The maximum differential head in the position obtained from the lifting and submersing curve	
2. Boundary of ballast water tank	The maximum differential head between two sides, not less than 3.5 m	
3. In way of air cushion space, such as the safety deck, longitudinal bulkhead plating, inner bulkhead plating of watertight ballast tank of superstructure	Internal head on the cushion side: differential head in the position under maximum submerged depth from the lifting and submersing curve. The head is taken as the differential between internal and external pressures, not less than 3.5 m	Also in compliance with the requirements in 1 and 2 above
4. Watertight boundary of empty tank	The vertical distance from the considered point to the deepest submersing water level, not less than 3.5 m	Also in compliance with the requirements in 3 above
5. Normal oil tanks, fresh water tanks and bilge tanks other than that mentioned above	The vertical distance from the considered point to the top of tank, or half of the vertical distance from the considered point to the top of overflow pipe, whichever is the greater	

17.4.2.2 The minimum thickness of boundary plating of tanks and non-watertight bulkheads is to be 7.5 mm.

17.4.3 Stiffeners on boundary plating

17.4.3.1 For structural members subjected to lateral pressure on tank boundary plating as defined in 17.4.2.1 of this Section, such as bulkhead stiffeners, longitudinals, beams and ordinary frames, etc., the minimum section modulus W is not to be less than that obtained from the following formula:

$$W = 7shl^2K \quad \text{cm}^3$$

where: s —spacing of stiffeners, in m;

K— material factor;

l — span of stiffener, in m, between effective supporting members;

h — calculated head, in m, see 17.4.2.1, measured from the mid span.

17.4.4 Top deck plating of superstructure on both sides

17.4.4.1 The plating thickness t of top deck of superstructure on both sides within the following two areas is not to be less than the value calculated from the following formulae, and not less than 6.5 mm:

$t = 10s\sqrt{K}$ mm, within $0.4L_D$ amidships

$t = (7.8s + 2.2)\sqrt{K}$ mm, $0.1L_D$ from each end of the pontoon

where: s — spacing of longitudinals, in m;

K — material factor.

17.4.4.2 The thickness of top deck plating within 0.4 L_D amidships is to be greater than that of the end.

17.4.5 Top deck longitudinals and beams of superstructure or deck house on both sides

17.4.5.1 The section modulus W of top deck longitudinals and beams of superstructure or deck house on both sides is not to be less than the value calculated from the following formula:

$$W = Csl^2 \qquad \text{cm}^3$$

where: C —14.5 for longitudinal beam within 0.4 L_D amidships, 5.4 for transverse beam and longitudinal beam at the fore and aft ends;

s — spacing of longitudinal or transverse beams, in m;

l — span of longitudinal or transverse beams, in m.

17.4.6 Safety deck plating

17.4.6.1 The thickness t of the safety deck plating is not to be less than that obtained from the following formula:

$$t = t_0 + 2.5$$

when $l/s < 4$, t_0 is to be multiplied by the factor: $1.1 - \dfrac{s}{2.5l}$

where: $t_0 = 3.4s\sqrt{hK}$ mm;

K — material factor;

s — spacing of stiffeners, in m;

l — span of stiffener, in m;

h — height from top of safety deck beam to top of upper deck beam at side, in m.

17.4.6.2 In addition to 17.4.6.1, special consideration is to be given to the thickness of safety deck where the deck is subjected to the air cushion and goods/equipment separately.

17.4.6.3 The minimum thickness of the safety deck plating is to be 7.5 mm.

17.4.7 Longitudinals and beams of safety deck

17.4.7.1 The section modulus W of each safety deck longitudinals or beams is to be obtained from the following formula:

$$W = 4.5Kshl^2 \quad \text{cm}^3$$

where: K — material factor;

s — spacing of stiffeners, in m;

l — span of stiffener, in m;

h — height from top of safety deck beam to top of upper deck beam at side, in m.

17.4.7.2 In addition to 17.4.7.1, special consideration is to be given to the check of scantlings where the deck is subjected to the air cushion and goods/equipment separately.

17.4.8 Webs, transverses, floors and girders

17.4.8.1 For primary supporting members such as webs, transverses, floors and girders, the minimum section modulus W is not to be less than that obtained from the following formula:

$$W = 7bhl^2K \qquad \text{cm}^3$$

where: b — supporting width, in m, spacing of primary supporting members;

K— material factor;

l — calculated span, in m;

h — calculated head, in m, see 17.4.3.1, measured from the mid span.

17.4.9 Cross ties

17.4.9.1 The sectional area, web and face plate of cross ties fitted in deck house on both sides and pontoon, are to be in accordance with the requirements of 17.4.9.4 and 17.4.9.5 of this Section.

17.4.9.2 The load P supported by the horizontal cross ties is not to be less than that obtained from the following formula:

$$P = p \qquad \text{kN}$$

where: $p = 9.8shl_1$;

where: h — maximum differential head, in m;

s — spacing of cross ties, in m;

l_1 — vertical midspan-to-midspan distance between two members immediately over and under the horizontal cross ties, in m, see Figure 17.4.9.3.

17.4.9.3 The load P supported by the diagonal cross ties is not to be less than that obtained from the following formula:

(1) For diagonal cross tie 1 (see Figure 17.4.9.3):

$$P = \frac{p \sin \beta}{\sin (\alpha + \beta)} \qquad \text{kN}$$

where: p — see 17.4.9.2, and h to be measured from the lower edge of diagonal cross ties to the water level at maximum differential head;

α, β — angles between diagonally arranged cross ties and horizontal plane, (º), see Figure 17.4.9.3.

(2) For diagonal cross tie 2 (see Figure 17.4.9.3):

$$P = \frac{p \sin \alpha}{\sin (\alpha + \beta)} \qquad \text{kN}$$

where: P, α and β — same as defined in (1).

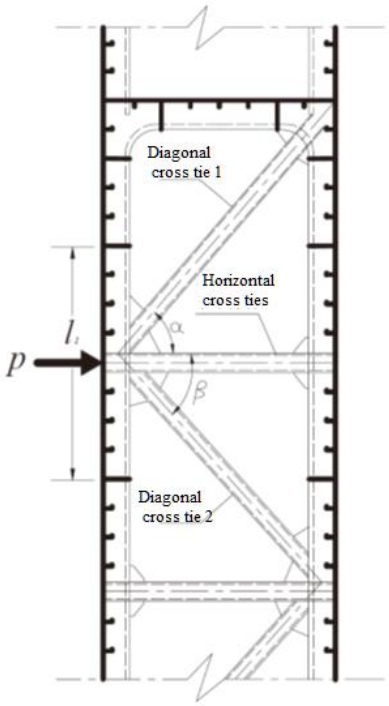

Figure 17.4.9.3 Vertical midspan-to-midspan Distance l_1 between Two Members immediately over and under the Horizontal Cross Ties

17.4.9.4 The cross-section area A of cross ties is to comply with the requirements of 2.10.2, Section 10, Chapter 2 of this PART.

17.4.9.5 The built or rolled-section cross ties are to comply with the requirements of 2.10.3.2, Section 10, Chapter 2 of this PART.

17.4.10 Local strength of pontoon supporting structure below the trolley rail

17.4.10.1 The local strength of pontoon supporting structure below the trolley rail may be calculated and analysed as specified in 17.2.2 of this Section, based on the loads subjected to the supporting structure throughout the length of pontoon. The strength criteria are given in 17.3.4.1 of this Section. Check of such local strength may be included in the direct calculation of global strength.

17.4.11 Platforms extending from ends of pontoon

17.4.11.1 The load supported by the platform structures is generally to be assumed as 5.75 kN/m^2, the permissible stress $[\sigma]$ to be $60/K$, N/mm^2 and the permissible shear stress $[\tau]$ to be $35/K$, N/mm^2. Where a large load is to be expected or required, special consideration is to be given.

17.4.12 Swing bridges at ends of pontoon

17.4.12.1 The load supported by the bridge structures of launching work barge is generally to be assumed as 3.59 kN/m^2, the permissible stress [σ] to be 60/K, N/mm^2 and the permissible shear stress [τ] to be 35/K, N/mm^2. Where a large load is to be expected or required, special consideration is to be given.

Section 5 DIRECT STRENGTH CALCULATION

17.5.1 General requirements

17.5.1.1 Direct calculation of global strength is to be carried out for launching work barges as required in Appendix 1 of this Chapter, and to be submitted to CCS.

Appendix 1 DIRECT STRENGTH CALCULATION OF LAUNCHING WORK BARGES

1 General Provisions

1.1 Application

1.1.1 This Appendix applies to the direct strength calculation of launching work barges required by this Chapter.

1.1.2 For those not covered in this Appendix, the relevant requirements of Section 9, Chapter 1 of this PART are to be complied with.

2 Design Loads

2.1 General requirements

2.1.1 The design loads are at least to include the following:

(1) self-weight of launching work barge;

(2) the weight of object intended for moving assumed in 17.2.2 of this Chapter only to be supported by pontoon;

(3) hydrostatic pressure of the outside of pontoon's bottom and external hydrostatic pressure;

(4) hydrostatic pressure on the immersed pontoon deck;

(5) hydrostatic pressure of the ballast tank.

3 Calculation Conditions

3.1 General requirements

3.1.1 The calculation conditions are at least to include the following, and to comply with the requirements of 17.2.2 of this Chapter and the characteristics of the ship:

(1) condition 1: the operating condition;

(2) condition 2: the condition that the top of the trolley bracket are just submerged by the water when the launching work barge is lifting at maximum capacity;

(3) condition 3: the severe condition likely to occur while distributing ballast water when the floating dock sinks or rises.

3.1.2 The equilibrium of total buoyancy and weight of model is to be maintained as far as possible, see 1.5.7.6 of Section 5, Chapter 1 of this PART.

3.1.3 In applying the load of the object intended for moving, the coordinate of the maximum value of the weight curve is to be assumed to be at the center of the global ship model.

4 Structural Modeling

4.1 General requirements

4.1.1 The extent of global ship model is as follows:

(1) for longitudinal extent (in x-direction): total length of the ship;

(2) for transverse extent (in y-direction): total breadth of the ship;

(3) for vertical extent (in z-direction): from baseline to the top deck.

4.1.2 The relevant requirements for model element and mesh scantling are given in Section 5, Chapter 1 of this PART.

4.1.3 The boundary conditions are to restrict the rigid displacement for the global ship model, in general, the boundary is to be placed at fore and aft ends or web frame section of amidships, see Figure 4.1.3.

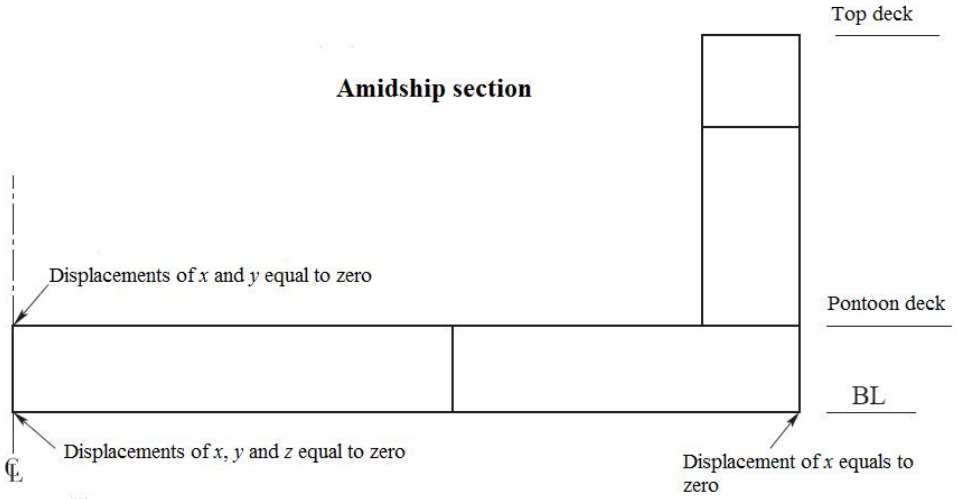

Figure 4.1.3 Boundary Conditions

5 Yielding Strength Assessment

5.1 Permissible stress

5.1.1 The permissible stress is given in Table 5.1.1.

Permissible Stress **Table 5.1.1**

Structural component	Equivalent stress or axial stress (N/mm^2)	Shear stress (N/mm^2)
Plate element	$[\sigma_e]$ =185/K	$[\tau]$ =100/ K
Trusses in transverse sections	$[\sigma]$=141/ K	–

Note: K— material factor.

6 Buckling Strength Assessment

6.1 General requirements

6.1.1 The requirements for buckling strength assessment are given in Appendix 1, Chapter 5 of this PART.

CHAPTER 18 TWIN-HULL CRAFT

Section 1 GENERAL PROVISIONS

18.1.1 General requirements

18.1.1.1 This Chapter applies to twin-hull craft of which the main body is composed of the two demi-hulls connected by cross-deck.

18.1.1.2 For those not covered in this Chapter, the relevant requirements of Chapter 2 of this PART are to be complied with.

18.1.2 Definitions

18.1.2.1 Length L (m) means the length measured along summer load line from the leading edge of the foremost vertical strut to the trailing edge of the aftermost vertical strut, plus 50% of difference between the length of lower hull from forward to end and the overall length of the underwater watertight envelope of the rigid hull (excluding appendages at or below the design waterline).

18.1.2.2 Breadth B (m) means the breadth of the broadest part of the moulded watertight envelope of the rigid hull, excluding appendages at or below the design waterline.

18.1.2.3 Moulded depth D (m) means the vertical distance measured at the middle of the length L from the top of keel to the lower surface of freeboard deck along the outside of demi-hull.

18.1.2.4 Breadth b (m) of demi-hull means the maximum horizontal distance measured at the middle of the length L between the outside surfaces of internal and external sides of demi-hull.

18.1.2.5 Breadth b_1 (m) of cross-deck structure means the horizontal distance measured at the middle of the length L between outside surfaces of internal sides of port and starboard sets of struts of wet deck.

18.1.2.6 Cross-deck structure means the deck and other accessory strength (boxlike) structure that spans the port and starboard sets of struts.

18.1.2.7 Wet deck means the lower plated surface of the cross structure.

18.1.2.8 Port and starboard sets of struts means the longitudinal mono-hull structures in way of both sides below the cross-deck structure, respectively.

18.1.3 Class notation

18.1.3.1 The class notation “Catamaran” is to be assigned to the twin-hull craft which comply with the provisions of this Chapter.

Section 2 STRUCTURAL STRENGTH

18.2.1 General requirements

18.2.1.1 For port or starboard set of strut of twin-hull craft, the applicable requirements for mono-hull craft of this PART may be complied with.

18.2.1.2 For cross-deck structure, the minimum scantling is to meet the requirements of the Rules for strength deck of mono-hull craft, and a suitable strengthening is to be provided for resistance to the slamming effect on wet deck of cross-deck structure by wave loads.

18.2.1.3 The overall strength (including longitudinal strength, transverse strength and torsional strength) of twin-hull craft with cross-deck structure is to be checked in accordance with the direct calculation of global strength of twin-hull craft as specified in Appendix 1 of this Chapter.

18.2.1.4 The shear strength of the longitudinal section of cross-deck structure is to be calculated and checked with the shear force as specified in 18.3.2.4 of this Chapter and the shear stress is to meet the requirements of the following formula (K is the material factor):

$$\tau \leqslant 90/K \quad \text{N/mm}^2$$

Section 3 TOTAL LOAD

18.3.1 General requirements

18.3.1.1 The total load of ship may be determined in accordance with 18.3.2 of this Section or direct calculation of load may be carried out in accordance with 18.3.1.2 and 18.3.1.3 of this Section (if applicable) for twin-hull passenger ship and public service ship with the following characteristics:

$$L \leqslant 60\ \text{m}$$
$$L/D \leqslant 15$$
$$B/D \leqslant 3.5$$
$$b_1/B \leqslant 0.4$$

18.3.1.2 The total load of twin-hull craft beyond the scope of 18.3.1.1 is to be determined by direct calculation. The direct calculation of wave loads is to be carried out in accordance with 2.2.9 of Section 2, Chapter 2 of this PART. If strip theory is adopted, the analysis is to consider the hydrodynamic interaction between twin hulls.

18.3.1.3 Where the wave loads are obtained directly from model testing, the related calculation principles/calculation procedure or test program (if applicable) is to be approved in advance.

18.3.2 Load under consideration

18.3.2.1 The longitudinal bending moment M_{by} of the twin-hull craft is the superposition of still water bending moment M_{bys} and wave bending moment M_{byw}. The wave bending moment M_{byw} is to be taken as twice the wave bending moment of the demi-hull which is to be determined in accordance with 2.2.3 of Section 2, Chapter 2 of this PART. The still water bending moment M_{bys} is to be determined in accordance with 2.2.2 of Section 2, Chapter 2 of this PART. The still water bending moment is to be taken as the maximum value within 0.4L midship under various loading conditions and the wave bending moment is to be taken within 0.4L midship.

18.3.2.2 The transverse bending moment M_{bx} of the cross-deck of twin-hull craft may be obtained by the following formula:

$$M_{bx} = 9.81 C_1 C_2 C_3 \Delta\ (b + b_1) \qquad \text{kN}\cdot\text{m}$$

where: $C_1 = 0.150(\frac{b}{D})^2 - 0.778\frac{b}{D} + 0.866$

$$C_2 = -2.386\frac{b_1}{B} + 1.937$$

where:

b — breadth of demi-hull, in m;

b_1 — breadth of cross-deck, in m;

D — moulded depth of craft, in m;

B — breadth of craft, in m;

C_3 — service coefficient, taken as 1.0;

Δ — displacement of twin-hull craft, in t.

18.3.2.3 The transverse torque M_{ty} of the cross-deck of twin-hull craft may be obtained by the following formula:

$$M_{ty} = 1.226 C_3 \Delta L \qquad \text{kN}\cdot\text{m}$$

where: C_3 — service coefficient, taken as 1.0;

Δ — displacement of twin-hull craft, in t;

L — length of craft, in m.

18.3.2.4 The vertical shear force Q_t of the cross-deck of twin-hull craft may be obtained by the following formula:

$$Q_t = 9.81 C_1 C_2 C_3 \Delta \qquad \text{kN}$$

where: $C_1 = 0.164(\frac{b}{D})^2 - 0.874\frac{b}{D} + 0.974$

$$C_2 = -1.958\frac{b_1}{B} + 1.783$$

where:

b — breadth of demi-hull, in m;

b_1 — breadth of cross-deck, in m;

D — moulded depth of craft, in m;

B — breadth of craft, in m;

C_3 — service coefficient, taken as 1.0;

Δ — displacement of twin-hull craft, in t.

Appendix 1 DIRECT STRENGTH CALCULATION OF TWIN-HULL CRAFT

1 General Provisions

1.1 General requirements

1.1.1 This Appendix applies to the direct strength calculation of twin-hull craft.

1.1.2 For those not covered in this Appendix, the relevant requirements of Section 5, Chapter 1 of this PART are to be complied with.

2 Loads

2.1 General requirements

2.1.1 During direct calculation, the loads may be applied in the form of equivalent loads as specified in 2.2.1 to 2.2.3 or may be carried out by the equivalent design wave method as specified in 2.2.4.

2.1.2 Where the equivalent loads are applied, the longitudinal bending moment M_{by}, transverse bending moment M_{bx}, transverse torque M_{ty} are to be calculated in accordance with Section 3 of this Chapter and the loads include still water loads and wave loads.

2.2 Application of loads

2.2.1 For longitudinal bending moment M_{by} of twin-hull craft, equivalent force $q(x)$ vertically distributed along craft length or a series of equivalent concentrated forces may be applied on calculation model. The loads are to be applied on longitudinal primary members of demi-hull, such as craft side, longitudinal bulkheads, bottom centre girders or other girders. The force acting on the same cross section of one hull may be divided into portions symmetrical to the longitudinal centerline section at port and starboard sides and the loads applied on two demi-hulls are to be symmetrical to the longitudinal centerline section of twin-hull craft. Where a series of concentrated forces are applied, each concentrated force is to be equal to the product of the distributed force multiplied by the length of areas loaded by the concentrated forces. $q(x)$ is to be obtained by the following formula:

$$q(x) = q_0\left(\sin\frac{\pi x}{L} - 0.637\right) \qquad \text{kN/m}$$

where: $q_0 = \dfrac{46}{L^2} M_{by}$ kN/m

where: M_{by} is to be calculated in accordance with 18.3.2.1 of this Chapter.

2.2.2 For transverse bending moment M_{bx} of cross-deck, its equivalency may be achieved by applying the transverse split force on the series nodes along the inside of the bilge of demi-hull, as shown in Figure 2.2.2. The transverse split force f_y is to be obtained by the following formula:

$$f_y = \frac{M_{bx}}{nz} \qquad \text{kN}$$

where: M_{bx} — transverse bending moment of cross-deck, in kN·m, to be calculated in accordance with this Chapter;

z — the vertical distance from the application point of transverse split force to neutral axis of the longitudinal centerline section of cross-deck, in m;

n — total number of nodes on which the transverse split force is applied for one demi-hull.

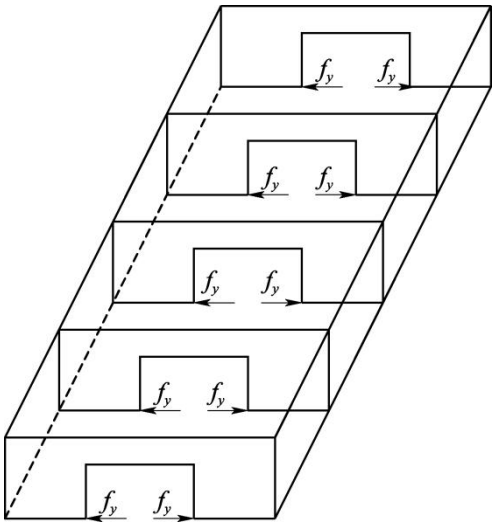

Figure 2.2.2 The application of transverse bending moment through transverse split force

2.2.3 For transverse torque M_{ty} of twin-hull craft, its equivalency may achieved by applying the uniformly distributed vertical force which is asymmetrically distributed on longitudinal centerline section of the demi-hull. "Asymmetrically distributed" means uniformly distributed equivalent vertical force, namely to be asymmetrically to the longitudinal centerline section and transverse centerline section of twin-hull craft, as shown in Figure 2.2.3. The uniformly distributed equivalent vertical load p_x is to be calculated by the following formula:

$$p_x = \frac{4M_{ty}}{L^2} \quad \text{kN/m}$$

where: L — length of twin-hull craft, in m;

M_{ty} — torque of cross-deck, in kN·m, to be calculated in accordance with this Chapter.

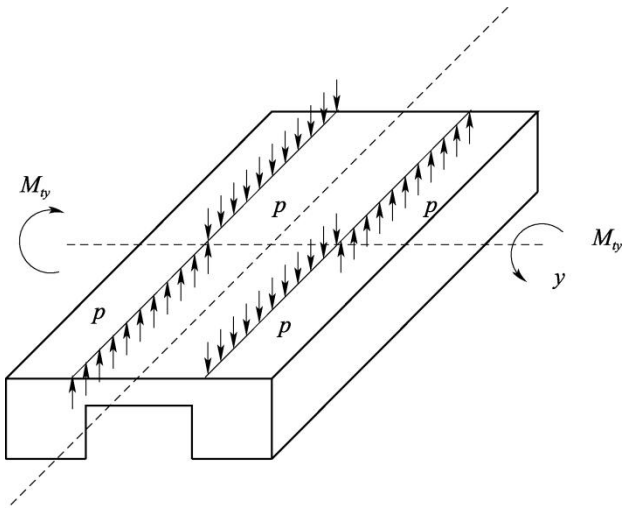

Figure 2.2.3 The application of transverse torque through asymmetrically distributed vertical force

2.2.4 The application of loads may also be carried out in accordance with 1.5.7 of Section 5, Chapter 1 of this PART. Relevant equivalent design wave is to be searched in accordance with the load combination conditions as specified in 3.1.1 of this Appendix.

3 Calculation Conditions

3.1 General requirements

3.1.1 The direct calculation of the structural strength of twin-hull craft is to be carried out in accordance with the load combination conditions (1) to (6) below and supplementary calculation is to be carried out in accordance with the load combination conditions (7) to (12) below for ships over 50 m in length:
(1) M_{bx} (inward);
(2) M_{bx} (outward);
(3) 0.8 M_{bx} (inward)＋0.6M_{ty};
(4) 0.8 M_{bx} (outward)＋0.6 M_{ty};
(5) 0.6 M_{bx} (inward)＋0.8 M_{ty};
(6) 0.6 M_{bx} (outward)＋0.8 M_{ty};
(7) M_{by} (hogging);
(8) M_{by} (sagging);
(9) 0.8 M_{by} (hogging)＋0.6 M_{ty};
(10) 0.8 M_{by} (sagging)＋0.6 M_{ty};
(11) 0.6 M_{by} (hogging)＋0.8 M_{ty};
(12) 0.6 M_{by} (sagging)＋0.8 M_{ty}.

4 Structural Modeling

4.1 General requirements

4.1.1 The global ship model is to contain all structural members of shell plating, longitudinal/transverse bulkheads, deck structure, cross-deck, struts, etc., of the hull structure.
4.1.2 The relevant requirements for model element and mesh scantling are given in Section 5, Chapter 1 of this PART.
4.1.3 In general, the following areas are to be subject to fine mesh analysis:
(1) interior angle in connection of the front end bulkhead of cross deck of twin-hull craft (or web beams) to twin hulls;
(2) interior angle in connection of the after end bulkhead of cross deck of twin-hull craft (or web beams) to twin hulls;
(3) positions in the actual structural shape that can not be expressed truly in any coarse mesh model;
(4) other areas where the stress considered for the global coarse mesh model exceeds 95% of the allowable stress.
4.1.4 During the fine mesh analysis, the mesh size of elements in refined area is not to be greater than 50 mm × 50 mm. The meshing is to be such that the transition from refined to coarse meshes is smooth.

4.2 Boundary conditions

4.2.1 For global FE model under an equilibrium condition, the boundary supports and constraint conditions given in Table 4.2.1 and Figure 4.2.1 may be used.

Boundary Conditions of Global FE Model **Table 4.2.1**

Position	Displacement constraint			Rotation constraint		
	δ_x	δ_y	δ_z	θ_x	θ_y	θ_z
Supporting point *A*	Cons.	Cons.	Cons.	–	–	–
Supporting point *B*	–	Cons.	Cons.	–	–	–
Supporting point *C* (*C'*)	–	– (Cons.)	Cons. (–)	–	–	–

Notes:
① The combination of *A*, *B*, *C'* is used for torsion condition, of which the point *C'* position in *z* direction is at wet deck of the cross-deck longitudinal centerline.
② In the case of longitudinal bending condition, the disequilibrium (if any) of force system in *z* direction may cause reaction of the additional supports in way of point *A* and point *B*. In this case, the results in way of point *A* and point *B* are to be neglected (such condition is for midship region only).

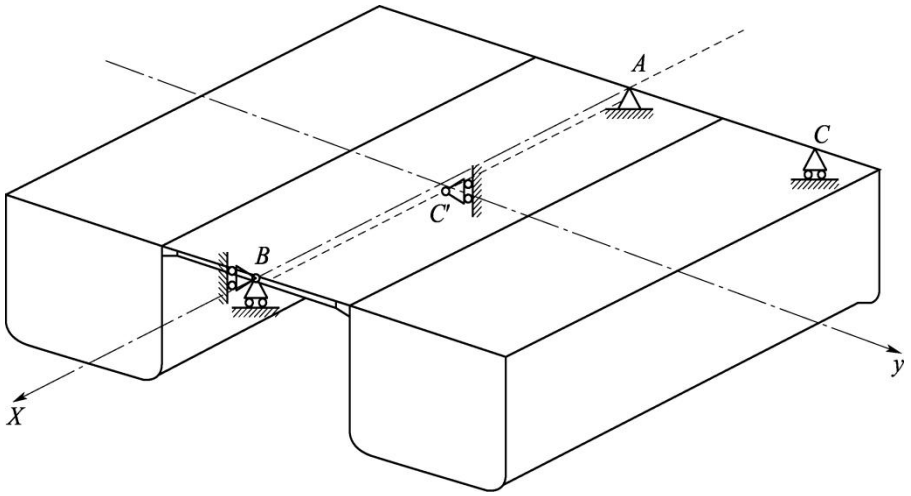

Figure 4.2.1

5 Yielding Strength Assessment

5.1 Permissible stress

5.1.1 The permissible stress is given in Table 5.1.1.

Permissible Stress **Table 5.1.1**

Structural component	Equivalent stress $[\sigma_e]$ (N/mm^2)	Shear stress $[\tau]$ (N/mm^2)
Plate element	200/K	90/K

Note: K— material factor.

5.1.2 Where the loads are applied in accordance with 2.2.1 to 2.2.3 of this Appendix, the equivalent stress of plate element within fine mesh area is not to be greater than $1.2\times235/K$ (K is material factor). Where the loads are applied through equivalent design wave in 2.2.4 of this Appendix, the equivalent stress of plate element within fine mesh area is not to be greater than $1.5\times235/K$ (K is material factor).

6 Buckling Strength Assessment

6.1 General requirements

6.1.1 The requirements for buckling strength assessment are given in Appendix 1, Chapter 5 of this PART.

CHAPTER 19 SAND CARRIERS

Section 1 GENERAL PROVISIONS

19.1.1 Application

19.1.1.1 This Chapter applies to self-discharging sand carriers (hereinafter referred to as sand carriers), with the transverse section of typical sand carriers given in Figures 19.1.1.1(1) and 19.1.1.1(2).

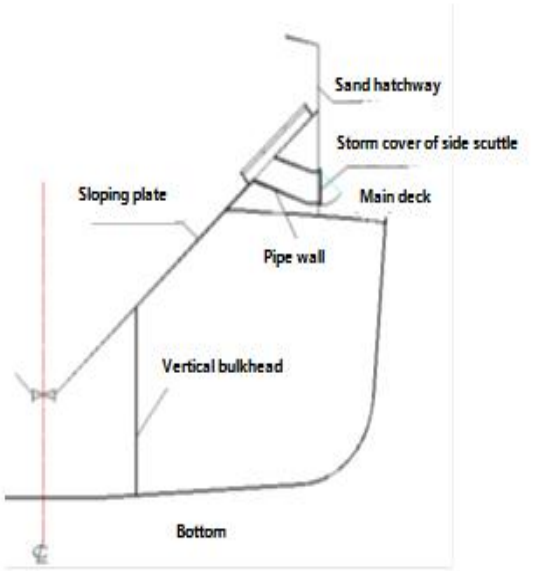

Figure 19.1.1.1(1)

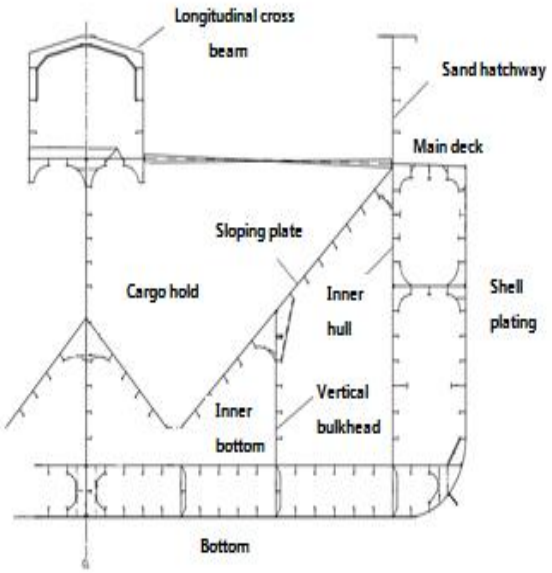

Figure 1 9.1.1.1(2)

19.1.1.2 This Chapter applies to the sand carriers with the main dimensions of $B/D \leq 3.5$.

19.1.1.3 For those not covered in this Chapter, the relevant requirements of Chapter 14 and Chapter 2 of this PART, as applicable, are also to be complied with.

19.1.2 Class notation

19.1.2.1 Ships complying with the requirements of this Chapter may be assigned with the class notation "Sand Carrier".

Section 2 SPECIAL REQUIREMENTS FOR STRUCTURES WITHIN SAND CARGO HOLD REGION

19.2.1 Sloping plate and its supporting structure

19.2.1.1 One bulkhead is to be provided under each sloping plate (at port and starboard), respectively for cargo hold fitted with sloping plates complying with the requirements of watertight bulkhead. The sloping structure of cargo hold is to meet the applicable requirements for hopper bulkheads in Chapter 14 of this PART and be in compliance with the requirements for hopper tanks in Chapter 8 of this PART.

19.2.1.2 The sectional area of bulkhead stiffeners or vertical webs with attached plating (bulkhead plating) is to comply with the requirements for pillars in Section 10, Chapter 2 of this PART. In calculation of the load P supported by pillars, P_0 is to be taken as the mud volumetric weight acting on sloping plate above within the loaded area $a \times b$.

19.2.1.3 For strength check of pillar under sloping plate, the mud volumetric weight acting on its above or the mud volumetric weight on hatch coamings and sloping plate supported by stiffeners is to be considered.

19.2.2 Bottom floors

19.2.2.1 For cargo hold structures in 19.2.1.1 above, the strength of bottom floors may be checked in accordance with the requirements of 14.5.2.1 of Section 5, Chapter 14 of this PART.

19.2.2.2 Vertical stiffeners are to be provided on web of solid floors for supporting pillars under sand hold

sloping plate between side longitudinal bulkheads and centerline, with the same thickness as that of the floor and 100 mm in width, both ends are to be snipped, see Figure 19.2.2.2.

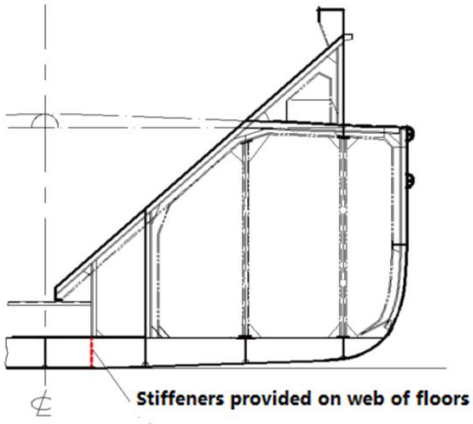

Figure 19.2.2.2 Stiffeners provided on web of floors

CHAPTER 20 MEMBRANE TANK LIQUEFIED GAS CARRIERS

Section 1 GENERAL PROVISIONS

20.1.1 Application

20.1.1.1 This Chapter applies to ships constructed with double hull side, double bottom, double deck and cofferdam transverse bulkheads, with engine room at stern and maximum vapor pressure less than 0.07 MPa, for the carriage of bulk liquefied natural gases in integral membrane type tanks.

20.1.1.2 For those not covered in this Chapter, the relevant applicable requirements of Chapters 1, 2 and 5 of this PART, and CCS Rules for Construction and Equipment of Ships Carrying Liquefied Gases in Bulk are to be complied with.

20.1.2 Class notations

20.1.2.1 Membrane tank liquefied gas carriers complying with the requirements of this Chapter will be eligible to be assigned the class notations as follows:

Liquefied Gas Carrier, Type XG, Membrane Tanks; Max. Vapour Pressure ××× MPa; Min. Cargo Temperature ×××℃; Max. Cargo Density ××× t/m^3; FL(××).

20.1.2.2 Ship mainly used for carrying one or some of the products listed in Chapter 19 of PART THREE of CCS Rules for Construction and Equipment of Ships Carrying Liquefied Gases in Bulk and complying with the requirements of this Chapter, "for + name of product" may be added after "Carrier" and the name of product is in accordance with column a of the List of Minimum Requirements in Chapter 19, PART THREE of CCS Rules for Construction and Equipment of Ships Carrying Liquefied Gases in Bulk, for example:

Liquefied Gas Carrier for Ethane, Ethylene

Membrane tank liquefied gas carriers specially used for carrying liquefied natural gas and complying with the requirements of this Chapter will be eligible to be assigned the class notations as follows:

LNG Carrier，Type 2G, Membrane Tanks; Max. Vapour Pressure ×××MPa; Min. Cargo Temperature ×××℃; Max. Cargo Density ××× t/m^3； FL(××)

20.1.2.3 A minimum design fatigue life of at least 20 years is specified in this Chapter. Where a membrane tank liquefied gas carrier is designed for a minimum design fatigue life of 25 years or more, the class notation FL (minimum design fatigue life) may be assigned at 5-year intervals starting from the 25th year, e.g. FL(25), FL(30), etc. For fatigue assessment based on spectrum analysis in accordance with the requirements of CCS Guidelines for Fatigue Strength Assessment of Ship Structure based on Spectrum Analysis, the service/route for which the ship is intended may be added in the class notation, e.g. SFA (NA, 25).

20.1.3 Plans and documents

20.1.3.1 Relevant applicable requirements of Chapter A3, PART TWO in CCS Rules for Construction and Equipment of Ships Carrying Liquefied Gases in Bulk are to be complied with in addition to the plans and documents specified in Section 1, Chapter 2 of this PART.

20.1.3.2 The following plans and documents related to the structural strength assessment of pump tower are also to be submitted for approval:

(1) pump tower arrangement;

(2) main structures of pump tower (including base foundations and liquid dome structures).

20.1.3.3 For the calculation of temperature field, the following plans and documents are also to be submitted for information:

(1) structure of insulation boxes;

(2) arrangement of insulations and details of their connections;

(3) temperature field calculation report.

20.1.4 Arrangement and structural configuration

20.1.4.1 The cargo tanks of membrane tank liquefied gas carriers are of complete double hull structure, having double side, double bottom, double deck and cofferdam transverse bulkheads. The dihedral between inner hull and inner deck/inner bottom is rendered 135° to reduce sloshing effects of cargo.

20.1.4.2 Cofferdams are to be provided forward of the foremost cargo tank and aft of the aftmost cargo tank as well as between cargo tanks. Integral double hull segregation is to be provided by cofferdams

between cargo tanks. For each cargo tank, the integral double hull is to be divided by void spaces including double bottom, double side, double deck and cofferdam transverse bulkheads.

20.1.4.3 Subdivision, width of double side and height of double bottom are to comply with the relevant requirements in Chapter 2, PART THREE of CCS Rules for Construction and Equipment of Ships Carrying Liquefied Gas in Bulk.

20.1.4.4 Structural configuration of cargo tanks

(1) Typical sketch of midship section and structural members of membrane tank liquefied gas carriers are shown in Figure 20.1.4.5.

Trunk deck is the continuous weather deck within cargo area and is higher than the upper deck.

Inner deck is the deck within cargo area and above the upper deck, forming a part of the inner hull in the ship.

(2) In general, the deck, bottom and inner bottom within cargo tank region of membrane tank liquefied gas carriers are to be longitudinally framed. The side shell and inner hull are also to be longitudinally framed. The hull structures beyond the cargo tank region may be framed either transversely or longitudinally. Constructional arrangements are to be made to ensure a gradual transition from the longitudinal framing to the transverse framing.

(3) The box framing of double deck of membrane tank liquefied gas carriers is formed by inner deck, upper deck and trunk deck as well as interconnected longitudinal girders and transverse floors.

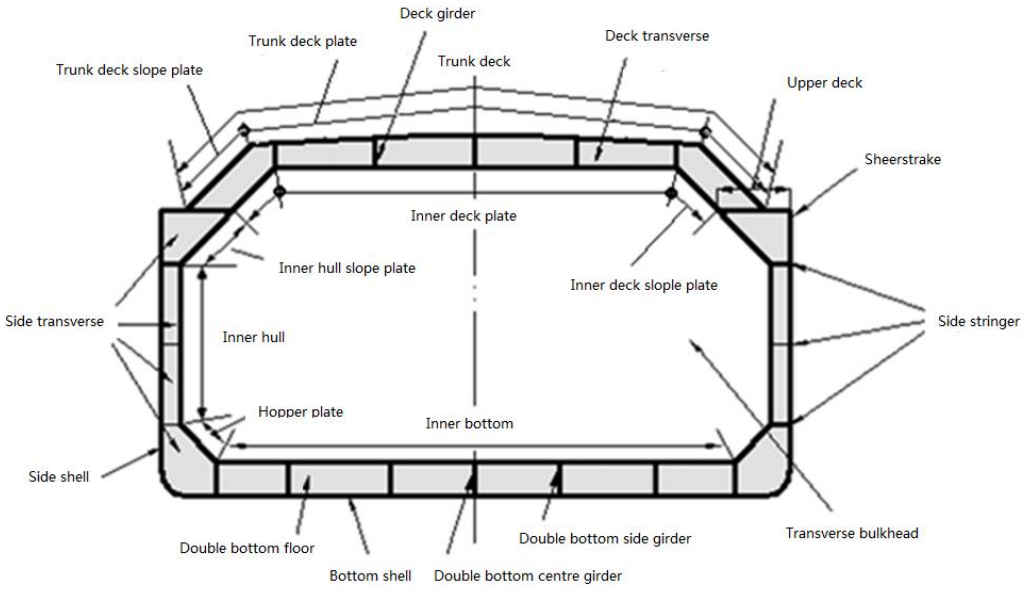

Figure 20.1.4.4 Typical sketch of midship section and structural members

(4) Cargo tanks are enclosed by double bottom, double side, cofferdams and double box trunk deck. Loading of fuel oil in double bottom, double hull, cofferdams and double box trunk deck directly adjacent to the insulation box of cargo tanks is not permitted.

20.1.4.5 Relevant requirements for cargo containment systems with regard to hull structural size and arrangement are to be approved by cargo containment system equipment manufacturer.

20.1.5 Minimum thickness

20.1.5.1 The minimum plate thickness for cargo tanks as well as other areas is to comply with the requirements of 5.1.6, Chapter 5 of this PART.

20.1.6 Direct calculation of hull structural strength

20.1.6.1 Direct calculation of structural strength related to membrane tank liquefied gas carriers is to be carried out according to the following requirements:

(1) for membrane tank liquefied gas carriers of 150 m in length and upward, hull structural strength assessment of direct calculations within the cargo tank region is to be carried out according to Appendix 1 of this Chapter;

(2) for membrane tank liquefied gas carriers with 4 and more cargo tanks or ship length of more than 250 m, direct calculation of global strength of ships is to be carried out according to Appendix 4 of this Chapter.

20.1.7 Structural strength under sloshing loads

20.1.7.1 The strength of the hull structure and pump tower structure of cargo tank region under sloshing loads, as well as of the liquid dome and base foundation structures of the pump tower, is to be checked and vibration evaluation of the pump tower structure is to be carried out according to the requirements of Appendix 2 of this Chapter.

20.1.8 Temperature field and thermal stress analysis

20.1.8.1 Appendix 3 of this Chapter applies to the temperature field prediction analysis of the hull structure and pump tower structure as well as thermal stress calculation of the pump tower structure of cargo tank region of membrane tank liquefied gas carriers under the low-temperature effect of the cargo, and the calculation report is to be submitted for information.

20.1.9 Fatigue assessment of hull structure

20.1.9.1 For membrane tank liquefied gas carriers of 150 m in length and upward, fatigue strength check is to be carried out for the following positions according to CCS Guidelines for Fatigue Strength of Ship Structure.:

(1) connection of longitudinals (bottom, side and deck) to transverse web frames;

(2) connections of longitudinals (bottom, side and deck) to transverse bulkheads;

(3) pump tower structures

For ships intended to apply for SFA notation, the fatigue strength check is to be carried out according to CCS Guidelines for Spectrum-based Fatigue Assessment of Hull Structure.

20.1.9.2 When implementing the requirements of 20.1.9.1 above, fatigue strength check is to be carried out by fine mesh finite element method to at least the following hull structures.

(1) the connection of lower and upper knuckle joints of hopper slope plating to inner bottom plating and inner hull longitudinal bulkhead in way of transverse web frames, as shown in Figure 20.1.9.2(1);

(2) the connection of inner bottom plating to transverse bulkhead in way of double bottom girder, as shown in Figure 20.1.9.2(2);

(3) the connection of inner hull plating to transverse bulkhead in way of double side stringer, as shown in Figure 20.1.9.2(3);

(4) the connection of liquid/gas dome opening and coaming to trunk deck, as shown in Figure 20.1.9.2(4).

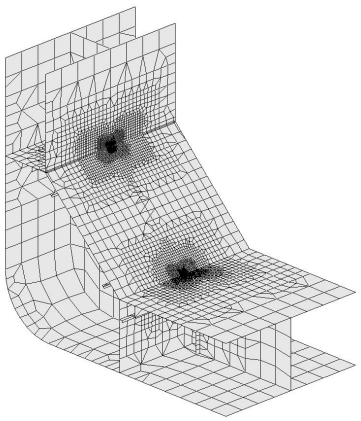

Figure 20.1.9.2(1) Connection of lower and upper knuckle joints of hopper slope plating to inner bottom plating and inner hull longitudinal bulkhead

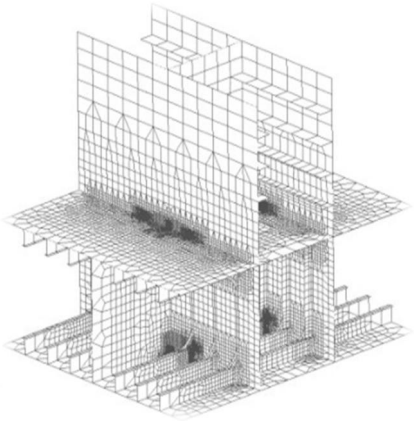

Figure 20.1.9.2(2) Connection of inner bottom plating to transverse bulkhead

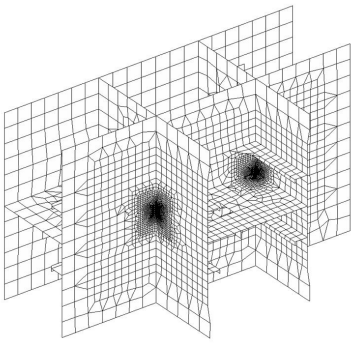

Figure 20.1.9.2(3) Connection of inner hull plating to transverse bulkhead

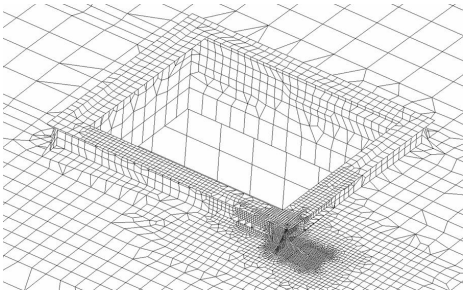

Figure 20.1.9.2(4) Connection of liquid/gas dome opening and coaming to trunk deck

Section 2 HULL GIRDER LONGITUDINAL STRENGTH AND ULTIMATE STRENGTH

20.2.1 Hull girder longitudinal strength

20.2.1.1 Membrane tank liquefied gas carriers are to comply with the longitudinal strength requirements specified in Section 2, Chapter 2 of this PART.

20.2.2 Hull girder ultimate strength

20.2.2.1 Evaluation of hull girder ultimate bending capacity within 0.4*L* amidships for intact hull structures in sea-going conditions is to be carried out to membrane tank liquefied gas carriers of 150 m in length and upward. Evaluation of hull girder ultimate bending capacity of membrane tank liquefied gas carriers of less than 150 m in length may also refer to the requirements of this Section.

20.2.2.2 Vertical hull girder ultimate bending capacity is to satisfy the following criterion:

$$\gamma_s \overline{M}_s + \gamma_w M_w \le \frac{M_U}{\gamma_R}$$

where:

$\overline{M}_s$ — permissible still water bending moment, in kN·m;

M_W — wave bending moment, in kN·m;

M_U — vertical hull girder ultimate bending moment, in kN·m;

$\gamma_s, \gamma_w, \gamma_R$ — partial safety factors, for membrane tank liquefied gas carriers,

γ_s=1.0,

γ_w=1.3,

$\gamma_R = \gamma_M \cdot \gamma_{DB}$

γ_M — partial safety factor, for membrane tank liquefied gas carriers, γ_M = 1.1;

γ_{DB} — to be taken as:

- γ_{DB} = 1.25 in hogging condition;
- γ_{DB} = 1.00 in sagging condition.

20.2.2.3 Curve *M*-χ

The ultimate bending moment of a hull girder transverse section, in hogging and sagging conditions, are defined as the maximum values of the curve of bending moment *M* versus the curvature χ of the transverse section considered (see Figure 20.2.2.3).

The curvature χ is positive for hogging condition and negative for sagging condition.

The curve *M*-$\chi$is to be obtained by means of an incremental-iterative approach in accordance with Appendix 2, Chapter 5, Part 9-1 of the Rules.

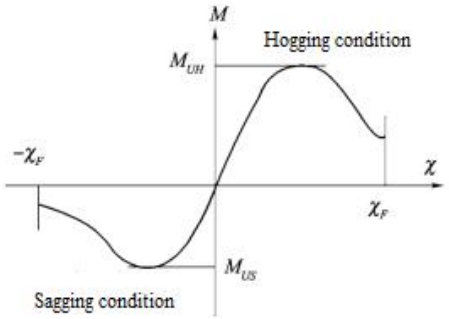

Figure 20.2.2.3 Curve Bending Moment *M* Versus Curvature χ

20.2.2.4 The hull girder transverse sections are constituted by the elements contributing to the hull girder longitudinal strength, and the standard thickness deduction given in Table 20.2.2.4 is to be deducted in calculation.

Standard Thickness Deduction **Table 20.2.2.4**

Structures	Standard thickness deduction, in mm
Trunk deck, trunk deck sloping plate	1
Side shell plating, sheer strake	1.5
Bilge strake, bottom plating and keel plate	1.25
Upper deck	1.25
Inner hull longitudinal bulkhead plating	1
Inner bottom plating	1
Horizontal girders in ballast tanks of double side	1.5
Girder in ballast tanks of double bottom	1.5
Side wall of pipe duct of double bottom	1.25
Structural members in ballast tanks	1.5
Structural members in dry spaces	0.5
Others	0.5

Section 3 SHELL PLATING

20.3.1 General requirements

20.3.1.1 Bottom shell, plate keel, side shell and sheer strake of membrane tank liquefied gas carriers are normally to be longitudinally framed.

20.3.1.2 The formulae in this Section apply to the determination of the thickness of longitudinally framed bottom shell, plate keel, bilge strakes, side shell and sheer strake within 0.4L amidships.

20.3.2 Bottom shell

20.3.2.1 The thickness t of bottom shell plating within 0.4L amidships is not to be less than the values obtained from the following formulae:

$$t_1 = 0.052 s_1 (L + 170)\sqrt{\frac{F_b}{K}} \quad \text{mm}$$

$$t_2 = 3.95 s \sqrt{K \rho_w h_1} + 2.5 \quad \text{mm}$$

where: s_1 — spacing of longitudinals, in m, not to be less than standard spacing of longitudinals;

s — spacing of longitudinals, in m;

L — length of ship, in m, need not be greater than 190 m;

K — material factor;

ρ_w — density of sea water, to be taken as 1.025 t/m^3;

F_b — reduction factor, see Section 2, Chapter 2 of this PART;

h_1 — to be taken according to following formula, in m;

$h_1 = h_0 - 0.35d$ if $Z = 0$;

$h_1 = h_0$ if $Z \geq d$;

Values in-between are obtained from linear interpolation.

h_0 — vertical distance, in m, measured from the lower edge of plate to the top of the tank, or half the distance to the top of overflow, whichever is the greater;

Z — vertical distance from base line to the point under consideration, in m;

Z_n — height of neutral axis, from base line, of hull cross section, in m;

d — draught, in m.

20.3.2.2 The breadth b of the plate keel within the cargo tank region is not to be less than that obtained from the following formula:

$$b = 900 + 3.5L \quad \text{mm}$$

The thickness of plate keel is not to be less than that of the adjacent bottom shell plating, and the thickness t is not to be less than the following value, if docking brackets are fitted in way of plate keel:

$$t = t_0 + 2.0 \quad \text{mm}$$

where: L — length of ship, in m;

t_0 — thickness of bottom shell plating defined by 20.3.2.1 of this Section, in mm.

20.3.3 Bilge strake

20.3.3.1 The thickness of bilge stakes within 0.4*L* amidships is not to be less than those of the adjacent bottom shell plating and side shell plating. See 5.2.4.2, Chapter 5 of this PART for the requirements of bilge strakes. In the case of higher tensile steel where the material factor for a lower strength level can still satisfy the requirements for plate buckling check in direct calculation, the value of *K* for a lower strength level may be taken.

20.3.4 Side shell plating

20.3.4.1 The thickness t of the side shell plating within 0.4L amidships is to comply with the following requirements:

(1) The thickness *t* of the side shell plating above $\frac{3}{4}D$ from base is not to be less than the values obtained from the following formulae:

$$t_1 = 0.058 s_1 (L_1 + 110)\sqrt{\frac{F_d}{K}} \quad \text{mm}$$

$$t_2 = 3.95 s\sqrt{\rho_w K h_1} + 2.5 \quad \text{mm}$$

(2) The thickness *t* of side shell plating below $\frac{1}{4}D$ from base is not to be less than the values obtained from the following formulae:

$$t_1 = 0.06 s_1 (L_1 + 110)\sqrt{\frac{F_b}{K}} \quad \text{mm}$$

$$t_2 = 3.95 s\sqrt{\rho_w K h_1} + 2.5 \quad \text{mm}$$

where: s — spacing of longitudinals, in m;

s_1 — spacing of longitudinals, in m, not to be less than standard spacing of longitudinals;

L — length of ship, in m, need not be greater than 190 m;

K — material factor;

ρ_w — density of sea water, to be taken as 1.025 t/m^3;

F_b, F_d — reduction factor, see Section 2, Chapter 2 of this PART;

h_1 — see 20.3.2.1 of this Section.

(3) For the formulae for the thickness *t* of side shell plating between $\frac{1}{4}D$ and $\frac{3}{4}D$ from base, see 5.2.5.1(3) of Chapter 5, where the plating thickness used for calculation is based on the results of 20.3.4.1(1) and (2) of this Section.

20.3.5 Sheer strake

20.3.5.1 The width of the sheer strake is to comply with the requirements of 5.2.6.1 of Chapter 5 of this PART.

20.3.5.2 Thickness *t* of sheer strake within 0.4*L* amidships is not to be less than the values obtained from the following formulae, nor less than that of the adjacent side shell plating or of the stringer plate of the upper deck:

$$t_1 = 0.06 s_1 (L_1 + 110)\sqrt{\frac{F_d}{K}} \quad \text{mm}$$

$$t_2 = 0.9 s_1 F_{c_deck}\sqrt{(L+80)K} + t_c \quad \text{mm}$$

where: s_1 — spacing of longitudinals, in m; not to be less than standard spacing of longitudinals;

L — length of ship, in m;

$L_1 = L$, where L is length of ship, in m, but need not be greater than 190 m;

$F_{c_deck} = 0.922\left[L/(L+80)\right]^{1/2}$;

F_d — reduction factor, see Section 2, Chapter 2 of this PART;

K — material factor;

t_c — corrosion allowance, for ballast tanks, to be taken as 2.5 mm; for cofferdams, to be taken as 1.0 mm.

Section 4 DECKS

20.4.1 General requirements

20.4.1.1 The formulae in this Section apply to the determination for thickness of trunk deck plating and upper deck plating within cargo tank region.

20.4.2 Trunk deck plating

20.4.2.1 Thickness of trunk deck plating

(1) Thickness t of trunk deck plating within 0.4L amidships is not to be less than the values obtained from the following formulae:

$$t_1 = 0.06 s_1 (L_1 + 110)\sqrt{\frac{F_d}{K}} \quad \text{mm}$$

$$t_2 = 0.9 s_1 F_{c_deck}\sqrt{(L+80)K} + t_c \quad \text{mm}$$

(2) Thickness t of trunk deck plating beyond 0.4L amidships within cargo tank region is not to be less than the values obtained from the following formulae, and is to be gradually tapered to end thickness of the cargo tank region:

$$t_1 = 0.06 s_1 (L_1 + 105)\sqrt{\frac{F_d}{K}} \quad \text{mm}$$

$$t_2 = 0.9 s_1 F_{c_deck}\sqrt{(L+80)K} + t_c \quad \text{mm}$$

where: s_1 — spacing of longitudinals, in m, which is not to be less than the standard spacing of longitudinals;

L— length of ship, in m;

$L_1 = L$, where L is length of ship, in m, need not be greater than 190 m;

K— material factor;

F_d — reduction factor, see Section 2, Chapter 2 of this PART;

$F_{c_deck} = 0.922\left[L/(L+80)\right]^{1/2}$;

t_c — corrosion allowance, for ballast tanks, to be taken as 2.5 mm; for cofferdams, to be taken as 1.0 mm.

20.4.2.2 Thickness of trunk deck slope plating

(1) Thickness t of trunk deck slope plating within 0.4L amidships is not to be less than the values obtained from the following formulae:

$$t_1 = 0.051 s_1 (L_1 + 115)\sqrt{\frac{F_d}{K}} \quad \text{mm}$$

$$t_2 = 0.9 s_1 F_{c_deck}\sqrt{(L+80)K} + t_c \quad \text{mm}$$

(2) Thickness t of trunk deck slope plating beyond 0.4L amidships within cargo tank region is not to be less than the values obtained from the following formulae, and is to be gradually tapered to end thickness of the cargo tank region:

$$t_1 = 0.051 s_1 (L_1 + 110)\sqrt{\frac{F_d}{K}} \quad \text{mm}$$

$$t_2 = 0.9 s_1 F_{c_deck}\sqrt{(L+80)K} + t_c \quad \text{mm}$$

For symbols in the formulae, see 20.4.2.1 of this Section.

20.4.3 Upper deck plating

20.4.3.1 Thickness t of upper deck plating within 0.4L amidships is not to be less than the values obtained from the following formulae:

$$t_1 = 0.06 s_1 (L_1 + 110)\sqrt{\frac{F_d}{K}} \quad \text{mm}$$

$$t_2 = 0.9 s_1 F_{c_deck}\sqrt{(L+80)K} + t_c \quad \text{mm}$$

$$t_3 = 3.95s\sqrt{K\rho_w h_0} + 2.5 \quad \text{mm, and not less than 7.5 mm}$$

where: s — spacing of longitudinals, in m;

s_1 — spacing of longitudinals, in m; not to be less than standard spacing of longitudinals;

L — length of ship, in m;

$L_1 = L$, where L is length of ship, in m, but need not be greater than 190 m;

K — material factor;

ρ_w — density of sea water, to be taken as 1.025 t/m^3;

F_d — reduction factor, see Section 2, Chapter 2 of this PART;

$$F_{c_deck} = 0.922\left[L/(L+80)\right]^{1/2};$$

h_0 — vertical distance, in m, measured from the lower edge of plate to the top of the tank, or half the distance to the top of overflow, whichever is the greater;

t_c — corrosion allowance, for ballast tanks, to be taken as 2.5 mm; for cofferdams, to be taken as 1.0 mm.

20.4.3.2 Thickness t of upper deck plating beyond 0.4L amidships within cargo tank region is not to be less than the values obtained from the following formulae, and is to be gradually tapered to end thickness of the cargo tank region:

$$t_1 = 0.06s_1(L_1 + 105)\sqrt{\frac{F_d}{K}} \quad \text{mm}$$

$$t_2 = 0.9s_1F_{c_deck}\sqrt{(L+80)K} + t_c \quad \text{mm}$$

$$t_3 = 3.95s\sqrt{K\rho_w h_0} + 2.5 \quad \text{mm , and not less than 7.5 mm}$$

For symbols in the formulae, see 20.4.3.1 of this Section.

Section 5 DECKS STRUCTURES

20.5.1 General requirements

20.5.1.1 Formulae in this Section apply to the determination of arrangement and scantlings of double box type trunk deck structures within cargo tank region.

20.5.2 Structural arrangement

20.5.2.1 Double box type trunk deck structures of membrane tank liquefied gas carriers are longitudinally framed by trunk deck, inner deck, deck transverses, deck girders and deck longitudinals.

20.5.2.2 Deck transverses are to be fitted in double box trunk deck in line with double bottom floors, and transverse framing or vertical webs in double side form transverse ring frames.

20.5.2.3 Deck girders are to be fitted in line with double bottom girders as far as possible, and deck girders are to be fitted in way of inner deck knuckle.

20.5.3 Deck girders

20.5.3.1 Side girders are to be fitted at the knuckle line of inner deck in double box trunk deck. The deck girders are to be equally spaced so far as practicable.

20.5.3.2 The web depth h of centre and side girders is not to be less than that obtained from the following formula:

$$h = 35B_e + 100 \quad \text{mm, and not less than 1,000 mm}$$

where: B_e —maximum breadth of trunk deck, in m, see Figure 20.5.3.2.

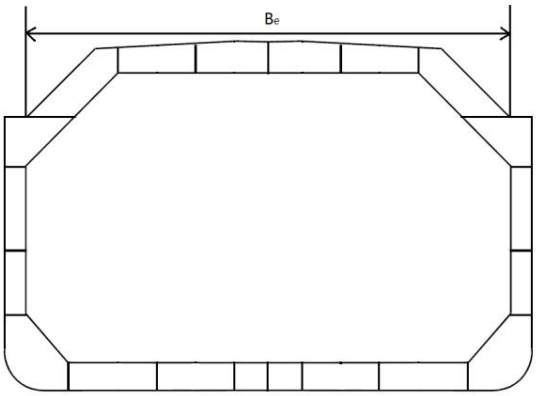

Figure 20.5.3.2 Maximum Breadth of Trunk Deck

20.5.3.3 The minimum web thickness t of centre girders is not to be less than that obtained from the following formula:

$t = (0.006h + 1.0)\sqrt{K}$ mm, but need not be greater than 16 mm

where: h — same as that specified in 20.5.3.2 of this Section;

K — material factor.

20.5.3.4 The minimum web thickness t of side girders is not to be less than that obtained from the following formula:

$t = (0.006h + 0.5)\sqrt{K}$ mm, but need not be greater than 16 mm

where: h — same as that specified in 20.5.3.2 of this Section;

K — material factor.

20.5.4 Deck transverses

20.5.4.1 Web thickness t of deck transverses is not to be less than that obtained from the following formula:

$$t = (0.006h + 0.5)\sqrt{K}$$, but need not be greater than 16 mm

where: h — same as that specified in 20.5.3.2 of this Section;

K — material factor.

20.5.4.2 Attention is to be paid to alignment where deck transverse webs are cut apart in way of deck girders so as to ensure the transverse continuity.

20.5.4.3 Vertical stiffeners are to be fitted between trunk deck longitudinals and inner deck longitudinals on deck transverse webs.

20.5.5 Trunk deck longitudinals

20.5.5.1 Section modulus W of trunk deck longitudinals is not to be less than that obtained from the following formula:

$$W = C_1 K s h l^2 \xi \qquad \text{cm}^3$$

where: l — span of longitudinals, in m, but not to be taken less than 2.5 m;

s — spacing of longitudinals, in m;

h — see 2.8.5.1, Chapter 2 of this PART;

K— material factor;

C_1 — coefficient, to be taken as 45;

ξ — coefficient, to be calculated according to following formula:

$$\xi = 0.47 - 1.065F_d + 0.839F_d^2$$

F_d — reduction factor, see Section 2, Chapter 2 of this PART.

20.5.5.2 Trunk deck longitudinals, in association with the trunk deck plating, may be gradually tapered outside 0.4L amidships towards the fore and aft ends of cargo tank region. At these ends, the section modulus of trunk deck longitudinals is not to be less than 90% of the value obtained from 20.5.5.1 of this Section.

20.5.5.3 Trunk deck longitudinals are to be continuous through the web of deck beams and welded to the web of deck transverses. These trunk deck longitudinals are to be welded to the stiffeners of deck transverses when intersecting such stiffeners.

20.5.6 Upper deck longitudinals

20.5.6.1 Section modulus W of upper deck longitudinals is not to be less than that obtained from the following formula:

$$W_1 = 8\rho_w Ksh_0 l^2 \quad \text{cm}^3$$

$$W_2 = C_1 Kshl^2 \xi \quad \text{cm}^3$$

where: s — spacing of longitudinals, in m;

l — span of longitudinals, in m, but not to be taken less than 2.5 m;

ρ_w — density of sea water, to be taken as 1.025 t/m^3;

h — see 2.8.5.1, Chapter 2 of this PART;

h_0 — vertical distance, in m, measured from center of the stiffener span to the top of the tank in way of the ship's longitudinal centerline section, or half the distance to the top of overflow, whichever is the greater;

K— material factor;

C_1 — coefficient, to be taken as 45;

ξ— coefficient, to be calculated according to following formula:

$$\xi = 0.47 - 1.065F_d + 0.839F_d^2$$

F_d — reduction factor, see Section 2, Chapter 2 of this PART.

20.5.6.2 Upper deck longitudinals, in association with the deck plating, may be gradually tapered outside 0.4L amidships towards the fore and aft ends. At 0.075L from the ends, the section modulus of deck longitudinals is not to be less than 80% of the value obtained from 20.5.6.1 of this Section, nor less than that required for deck longitudinals at the ends of the ship in 2.8.5.1, Chapter 2 of this PART.

20.5.6.3 Connections of upper deck longitudinals to watertight transverse bulkheads are to provide adequate fixity and upper deck longitudinals are to be continuous through the transverse bulkheads.

20.5.7 Inner deck plating

20.5.7.1 Thickness of inner deck plating

(1) Thickness t of inner deck plating within 0.4L amidships is not to be less than the values obtained from the following formulae:

$$t_1 = 0.06s_1(L_1 + 110)\sqrt{\frac{F_d}{K}} \quad \text{mm}$$

$$t_2 = 0.9s_1 F_{c_deck}\sqrt{(L+80)K} + t_c \quad \text{mm}$$

$$t_3 = 40s\sqrt{KP_{eq}} + 1.0 \quad \text{mm}$$

(2) Thickness t of inner deck plating beyond 0.4L amidships within cargo tank region is not to be less than the values obtained from the following formulae, and is to be gradually tapered to end thickness of the cargo tank region:

$$t_1 = 0.06s_1(L_1 + 105)\sqrt{\frac{F_d}{K}} \quad \text{mm}$$

$$t_2 = 0.9s_1 F_{c_deck}\sqrt{(L+80)K} + t_c \quad \text{mm}$$

$$t_3 = 40s\sqrt{KP_{eq}} + 1.0 \quad \text{mm}$$

where: s — spacing of longitudinals, in m;

s_1 — spacing of longitudinals, in m, which is not to be less than the standard spacing of longitudinals;

L— length of ship, in m;

$L_1 = L$, where L is length of ship, in m, need not be greater than 190 m;

K— material factor;

F_d— reduction factor, see Section 2, Chapter 2 of this PART;

$F_{c_deck} = 0.922\left[L/(L+80)\right]^{1/2}$;

P_{eq} — internal pressure of tank, in MPa, as defined in 4.13.2.4, Chapter 4, PART THREE of CCS Rules for the Construction and Equipment of Ships Carrying Liquefied Gases in Bulk;

t_c — corrosion allowance, for ballast tanks, to be taken as 2.5 mm; for cofferdams, to be taken as 1.0 mm.

20.5.7.2 Thickness of inner deck slope plating

(1) Thickness t of inner deck slope plating within 0.4L amidships is not to be less than the values obtained from the following formulae:

$$t_1 = 0.06 s_1 (L_1 + 110)\sqrt{\frac{F_d}{K}} \quad \text{mm}$$

$$t_2 = 0.9 s_1 F_{c_deck}\sqrt{(L+80)K} + t_c \quad \text{mm}$$

$$t_3 = 40 s\sqrt{KP_{eq}} + 1.0 \quad \text{mm}$$

(2) Thickness t of inner deck slope plating beyond 0.4L amidships within cargo tank region is not to be less than the values obtained from the following formulae, and is to be gradually tapered to end thickness of the cargo tank region:

$$t_1 = 0.05 s_1 (L_1 + 110)\sqrt{\frac{F_d}{K}} \quad \text{mm}$$

$$t_2 = 0.9 s_1 F_{c_deck}\sqrt{(L+80)K} + t_c \quad \text{mm}$$

$$t_3 = 40 s\sqrt{KP_{eq}} + 1.0 \quad \text{mm}$$

For symbols in the formulae, see 20.5.7.1 of this Section.

20.5.8 Inner deck longitudinals

20.5.8.1 Section modulus W of inner deck top plating longitudinals is not to be less than the value obtained from the following formula:

$$W = 644 KsP_{eq} l^2 \quad \text{cm}^3$$

where: s — spacing of longitudinals, in m;

l — span of longitudinals, in m, but not to be taken less than 2.5 m;

K — material factor;

P_{eq} — internal pressure of tank, in MPa, as defined in 4.13.2.4, Chapter 4, PART THREE of CCS Rules for the Construction and Equipment of Ships Carrying Liquefied Gases in Bulk.

20.5.8.2 Section modulus W of inner deck slope plating longitudinals is not to be less than the value obtained from the following formula:

$$W = 560 KsP_{eq} l^2 \quad \text{cm}^3$$

where: symbols — see 20.5.8.1 in this Section.

20.5.8.3 Inner deck longitudinals, in association with the inner deck plating, may be gradually tapered outside 0.4L amidships towards the fore and aft ends of cargo tank region. At these ends, the section modulus of inner deck longitudinals is not to be less than 90% of the value obtained from (1) above.

20.5.8.4 Connections of inner deck longitudinals to transverse bulkheads are to provide adequate fixity and the inner deck longitudinals are to be continuous through the webs of deck transverses. Inner deck longitudinals are to be welded to the web of deck transverses, and to be welded to the stiffeners of deck transverses when intersecting such stiffeners.

Section 6 DOUBLE SKIN CONSTRUCTION

20.6.1 General requirements

20.6.1.1 This Section is applicable to the determination of arrangement and scantlings of frames in double side within the cargo tank region.

20.6.1.2 Those uncovered in this Section are to comply with the provisions in Section 5, Chapter 5 of this PART.

20.6.2 Side longitudinals

20.6.2.1 Section modulus W of side longitudinals is not to be less than that obtained from the following formula:

$$W_1 = \frac{8.5}{f} Kshl^2 \quad \text{cm}^3$$

$$W_2 = 8K\rho_w s h_1 l^2 \quad \text{cm}^3$$

where: s— spacing of longitudinals, in m;

l — span of longitudinals, in m;

K— material factor;

f — factor, to be taken according to following formula and not to be greater than 1.077:

$$f=\begin{cases}1.73-F_d\dfrac{Z-Z_n}{D-Z_n} & \text{if } Z\geq Z_n;\\ 1.73-F_d\dfrac{Z_n-Z}{Z_n} & \text{if } Z<Z_n\end{cases}$$

h — design pressure head, in m, to be taken from the following formula:

$$h=0.26C+d-\frac{Z}{D}\left(0.06C+d\right)$$

C — see Section 2, Chapter 2 of this PART;

D — moulded depth, in m;

h_1— to be taken according to following formula, in m:

$h_1=h_0-0.35d$, if $Z=0$;

$h_1=h_0$, if $Z\geq d$

Values in-between are obtained from linear interpolation.

h_0 — vertical distance, in m, measured from the center of stiffener span to the top of the tank, or half the distance to the top of overflow, whichever is the greater;

Z — vertical distance from base line to the calculation point, in m;

Z_n — height of neutral axis, from base line, of the hull cross section calculated, in m;

d — draught, in m;

ρ_w — density of sea water, to be taken as 1.025 t/m^3.

20.6.3 Inner hull slope plating and its longitudinals

20.6.3.1 The thickness of inner hull slope plating is not to be less than the values obtained from the following formulae nor less than that of the adjacent inner deck sloping plate:

$$t_1=40s\sqrt{KP_{eq}}+1.0 \quad \text{mm}$$

$$t_2=3.95s\sqrt{K\rho_w h_0}+2.5 \quad \text{mm}$$

where: s — spacing of longitudinals, in m;

K — material factor;

ρ_w — density of sea water, to be taken as 1.025 t/m^3;

h_0 — vertical distance, in m, measured from the lower edge of the plate to the top of the tank, or half the distance to the top of overflow, whichever is the greater;

P_{eq} — internal pressure of tank, in MPa, as defined in 4.13.2.4, Chapter 4, PART THREE of CCS Rules for the Construction and Equipment of Ships Carrying Liquefied Gases in Bulk.

20.6.3.2 The section modulus W of longitudinals of inner hull slope plating is not to be less than the values obtained from the following formulae nor less than that of the adjacent inner hull plating longitudinals:

$$W_1=560KsP_{eq}l^2 \quad \text{cm}^3$$

$$W_2=8K\rho_w s h_0 l^2 \quad \text{cm}^3$$

where: l — span of longitudinals, in m;

h_0 — vertical distance, in m, measured from the center of stiffener span to the top of the tank, or half the distance to the top of overflow, whichever is the greater;

For other symbols, see 20.6.3.1 of this Section.

20.6.4 Inner hull plating and its longitudinals

20.6.4.1 The thickness of inner hull plating is not to be less than the values obtained from the following formulae:

$$t_1=40s\sqrt{KP_{eq}}+1.0 \quad \text{mm}$$

$$t_2=3.95s\sqrt{K\rho_w h_0}+2.5 \quad \text{mm}$$

where: s — spacing of longitudinals, in m;

K — material factor;

ρ_w — density of sea water, to be taken as 1.025 t/m^3;

h_0 — vertical distance, in m, measured from the lower edge of the plate to the top of the tank, or half the distance to the top of overflow, whichever is the greater;

P_{eq} — internal pressure of tank, in MPa, as defined in 4.13.2.4, Chapter 4, PART THREE of CCS Rules for the Construction and Equipment of Ships Carrying Liquefied Gases in Bulk.

20.6.4.2 The spacing of longitudinals of inner hull plating is the same as that of side shell longitudinals, and the section modulus W is not to be less than the values obtained from the following formulae:

$$W_1 = 560KsP_{eq}l^2 \quad \text{cm}^3$$

$$W_2 = 8K\rho_w s h_0 l^2 \quad \text{cm}^3$$

where: l — span of longitudinals, in m;

h_0 — vertical distance, in m, measured from the center of stiffener span to the top of the tank, or half the distance to the top of overflow, whichever is the greater;

For other symbols, see 20.6.4.1 of this Section.

20.6.5 Hopper slope plating and its longitudinals

20.6.5.1 The thickness of hopper slope plating is not to be less than the values obtained from the following formulae nor less than that of the adjacent inner hull plating:

$$t_1 = 40s\sqrt{KP_{eq}} + 1.0 \quad \text{mm}$$

$$t_2 = 3.95s\sqrt{K\rho_w h_0} + 2.5 \quad \text{mm}$$

where: s — spacing of longitudinals, in m;

K — material factor;

ρ_w — density of sea water, to be taken as 1.025 t/m^3;

h_0 — vertical distance, in m, measured from the lower edge of the plate to the top of the tank, or half the distance to the top of overflow, whichever is the greater;

P_{eq} — internal pressure of tank, in MPa, as defined in 4.13.2.4, Chapter 4, PART THREE of CCS Rules for the Construction and Equipment of Ships Carrying Liquefied Gases in Bulk.

20.6.5.2 The section modulus of hopper slope plating longitudinals is not to be less than the values obtained from the following formulae nor less than that of the adjacent inner hull plating longitudinals:

$$W_1 = 560KsP_{eq}l^2 \quad \text{cm}^3$$

$$W_2 = 8K\rho_w s h_0 l^2 \quad \text{cm}^3$$

where: l — span of longitudinals, in m;

h_0 — vertical distance, in m, measured from the center of stiffener span to the top of the tank, or half the distance to the top of overflow, whichever is the greater;

For other symbols, see 20.6.5.1 of this Section.

20.6.6 Stringers in double side

20.6.6.1 Structural requirements related to stringers in double side are to comply with the provisions in 5.5.6, Chapter 5 of this PART.

20.6.7 Transverse bulkheads in double side

20.6.7.1 Structural requirements related to transverse bulkheads in double side are to comply with the provisions in 5.5.7, Chapter 5 of this PART.

Section 7 DOUBLE BOTTOM STRUCTURE

20.7.1 General requirements

20.7.1.1 Unless specified otherwise in this Section, the scantlings and arrangement of the double bottoms in cargo tank region are to be as required in Section 4, Chapter 5 of this PART.

20.7.2 Bottom girders

20.7.2.1 The centre girders are to be arranged at the longitudinal centerline of double bottoms. Side girders are also to be provided at sides. At least two side girders spaced apart generally not more than 4 m are to be fitted on each side of the centerline. Side girders are to be equally spaced as far as applicable.

20.7.2.2 Side girders are to be provided in way of hopper slope plating. Additional local girders are to be arranged within double bottom in way of vertical diaphragm of transverse bulkheads. The spacing of longitudinal girders (including local girders) is generally not to exceed four longitudinal spacings, and the

thickness is in general not to be less than that of the lowest strake of the vertical diaphragm, and is to comply with the requirements of 5.4.2, Chapter 5 of this PART.

20.7.3 Bottom floors

20.7.3.1 Spacing of bottom floors is, in general, not to be greater than (0.006L + 3.2) m nor 4.2 m (whichever is lesser), L being length of ship.

20.7.3.2 Thickness of bottom floors t is not to be less than the value obtained by the following formula:

$$t = (0.006h + 1.0)\sqrt{K} \text{ mm, but it need not be greater than 12 mm}$$

where: h — considered height of centre girders, in mm, see 2.6.2.1 of Section 6 of Chapter 2 of this PART;

K — material factor.

20.7.4 Bilge brackets

20.7.4.1 Structural requirements related to bilge brackets are to comply with the provisions in 5.4.4, Chapter 5 of this PART.

20.7.5 Bottom longitudinals

20.7.5.1 Section modulus W of bottom longitudinals is not to be less than that obtained from the following formulae:

$$W_1 = \frac{8.5}{1.73 - F_b}(d + h)sl^2K \quad \text{cm}^3$$

$$W = 8K\rho_w s h_1 l^2 \quad \text{cm}^3$$

where: s — spacing of longitudinals, in m;

l — span of longitudinals, in m;

K — material factor;

ρ_w — density of sea water, to be taken as 1.025 t/m^3;

h_1 — see 20.6.2.1 of this Section;

$h = 0.26C$, not to be greater than $0.2d$ for calculation;

d — draught, in m;

C — coefficient, see 2.2.3.1, Section 2, Chapter TWO of this PART;

F_b — deduction factor, see Section 2, Chapter TWO of this PART.

The bottom longitudinals in way of pipe tunnels are only to satisfy the above-mentioned requirements of section modulus W_1.

20.7.6 Inner bottom plating and inner bottom longitudinals

20.7.6.1 The thickness t of inner bottom plating is not to be less than the values obtained from the following formulae:

$$t_1 = 40s\sqrt{KP_{eq}} + 1.0 \quad \text{mm}$$

$$t_2 = 3.95s\sqrt{K\rho_w h_0} + 2.5 \quad \text{mm}$$

where: s — spacing of longitudinals, in m;

K — material factor;

ρ_w — density of sea water, to be taken as 1.025 t/m^3;

h_0 — vertical distance, in m, measured from the lower edge of the plate to the top of the tank, or half the distance to the top of overflow, whichever is the greater. Where the inner bottom plating is located in dry space or void space, h_0 is to be measured from the lower edge of plating to be calculated to the deepest equilibrium waterline obtained from damage stability calculation, and not to be less than the vertical distance measured from lower edge of plating to freeboard deck;

P_{eq} — internal pressure of tank, in MPa, as defined in 4.13.2.4, Chapter 4, PART THREE of CCS Rules for the Construction and Equipment of Ships Carrying Liquefied Gases in Bulk.

20.7.6.2 Section modulus W of inner bottom longitudinals is not to be less than the values obtained from the following formulae:

$$W_1 = 560KsP_{eq}l^2 \quad \text{cm}^3$$

$$W_2 = 8K\rho_w s h_0 l^2 \quad \text{cm}^3$$

where: l — span of longitudinals, in m;

h_0 — vertical distance, in m, measured from the center of stiffener span to the top of the tank, or half the distance to the top of overflow, whichever is the greater. Where the inner bottom plating is located in dry space or void space, h_0 is to be measured from the lower edge of mid-point of span for member to be calculated to the deepest equilibrium waterline obtained from damage stability calculation, and not to be less than the vertical distance measured from lower edge of plating to freeboard deck;

For other symbols, see 20.7.6.1 of this Section.

Section 8 PLANE TRANSVERSE BULKHEAD STRUCTURES

20.8.1 General requirements

20.8.1.1 Cofferdam transverse bulkhead structures, consisting of horizontal stringers and vertical diaphragm between transverse bulkheads and horizontal or vertical stiffeners of transverse bulkhead, are to be provided between cargo tanks of membrane tank liquefied gas carriers. Manholes are to be cut in the vertical diaphragm and horizontal stringers in accordance with the requirements in Section 9 of this Chapter. Cofferdams are to be provided between cofferdam transverse bulkheads.

20.8.1.2 Solid floors are to be provided within the double bottom in way of cofferdam transverse bulkheads. Vertical diaphragm of cofferdam transverse bulkheads is to be in alignment with girders or local girders in the double bottom and in double box trunk deck.

20.8.1.3 The horizontal stringers of cofferdam transverse bulkheads are to be in line with those of the inner side. Vertical stiffeners of the cofferdam transverse bulkheads are to be in line with longitudinals of inner deck and inner bottom. Horizontal stiffeners of cofferdam transverse bulkheads are to be in line with longitudinals of inner hull, inner deck slope plating, inner hull slope plating and hopper slope plating.

20.8.2 Thickness of bulkhead plating

20.8.2.1 Thickness t of bulkhead plating is not to be less than the values obtained from the following formulae:

$$t_1 = 40s\sqrt{KP_{eq}} + 1.0 \quad \text{mm}$$

$$t_2 = 3.95s\sqrt{K\rho_c h_0} + 2.5 \quad \text{mm}$$

$$t_3 = 4.0s\sqrt{K\rho_w h_2} \quad \text{mm}$$

where: s — spacing of stiffeners, in m;

K — material factor;

ρ_w — density of sea water, to be taken as 1.025 t/m^3;

ρ_c — density of liquid cargo, to be taken as 0.50 t/m^3 for LNG;

h_0 — vertical distance, in m, measured from the lower edge of bulkhead plate to the top of the tank in way of the ship's longitudinal centerline section, or half the distance to the top of overflow, whichever is the greater;

h_2 — vertical distance, in m, measured from the lower edge of bulkhead plate to the bulkhead deck;

P_{eq} — internal pressure of tank, in MPa, as defined in 4.13.2.4, Chapter 4, PART THREE of CCS Rules for the Construction and Equipment of Ships Carrying Liquefied Gases in Bulk.

20.8.2.2 Thickness of bulkhead plating is also to comply with the requirements of 5.7.2.2, Chapter 5 of this PART, if applicable.

20.8.3 Horizontal stringers and vertical diaphragm

20.8.3.1 Thickness of horizontal stringers and vertical diaphragm is to comply with the requirements of 20.1.5 of this Chapter.

20.8.3.2 Scantlings of stiffeners of horizontal stringers and vertical diaphragm are to comply with Section 9 of this Chapter.

20.8.4 Vertical stiffeners

20.8.4.1 Section modulus W of vertical stiffeners is not to be less than the values obtained from the following formulae:

$$W_1 = 560KsP_{eq}l^2 \quad cm^3$$

$$W_2 = 8K\rho_c sh_0 l^2 \quad cm^3$$

$$W_3 = CKsh_2l^2 \qquad cm^3$$

where: s — spacing of stiffeners, in m;
l — span of stiffeners, in m;
K — material factor;
P_c — density of liquid cargo, to be taken as 0.50 t/m^3 for LNG;
P_{eq} — internal pressure of tank, in MPa, as defined in 4.13.2.4, Chapter 4, PART THREE of CCS Rules for the Construction and Equipment of Ships Carrying Liquefied Gases in Bulk;
h_0 — vertical distance, in m, measured from the center of stiffener span to the top of the tank in way of the ship's longitudinal centerline section, or half the distance to the top of overflow, whichever is the greater;
h_2 — vertical distance, in m, measured from the center of stiffener span to the bulkhead deck, and not to be less than $0.25D$, where: D is the moulded depth, in m;
C — coefficient, to be taken as follows:
C = 6, for stiffeners unattached at both ends, or directly attached to unstiffened plating;
C = 3, for stiffeners bracketed at ends, or directly lapped to longitudinal members at ends.

20.8.5 Horizontal stiffeners

20.8.5.1 Section modulus W of horizontal stiffeners is not to be less than the values obtained from the following formulae:

$$W_1 = 560KsP_{eq}l^2 \qquad \text{cm}^3$$

$$W_2 = 8K\rho_c sh_0l^2 \qquad \text{cm}^3$$

$$W_3 = CKsh_2l^2 \qquad \text{cm}^3$$

where: h_2 — vertical distance, in m, from the stiffeners considered to the moulded depth, but not to be less than $0.25D$; D is the moulded depth, in m;
l — span of longitudinals, in m;
Other symbols — see 20.8.4.1 of this Section.

20.8.5.2 The horizontal stiffeners are to be in line with the longitudinals of inner hull, inner deck slope plating, inner hull slope plating and hopper slope plating with end brackets having the scantlings as required by Chapter 1 of this PART. Horizontal stiffeners are to be welded to the vertical diaphragm and their stiffeners when penetrating vertical diaphragm.

Section 9 STRUCTURAL DETAILS

20.9.1 General requirements

20.9.1.1 Those uncovered in this Section (excluding sloshing assessment) are to comply with the provisions of Section 12, Chapter 5 of this PART, if applicable.

20.9.1.2 When a knuckle is arranged in a primary member (shell plate, longitudinal bulkhead etc.), stiffening in the form of deep web is to be provided at the knuckle to transmit the transverse load and is to be connected to the transverse members to which they are to transfer the load (in shear). For longitudinal shallow knuckles, closely spaced carlings may be fitted across the knuckle, between longitudinal members above and below the knuckle. Carlings or other reinforcements need not be fitted in way of shallow knuckles that are not subject to high lateral loads or high in-plane loads across the knuckle, such as deck camber knuckles.

20.9.2 Openings

20.9.2.1 Structural details of openings are to comply with the requirements of 1.2.5.5, Chapter 1 of this PART. Manholes, lightening holes and other similar openings are to be avoided in way of concentrated loads and areas of high shear, such as: floors or double bottom girders close to their span ends.

Where openings are unavoidable, the strength at the openings is to comply with the relevant requirements for yield and buckling assessment of panels.

Where openings larger than those given by 20.9.2.2 or 20.9.2.3 of this Section are proposed, the arrangements and compensation required will be specially considered.

20.9.2.2 For manholes and lightening holes in single skin sections not requiring reinforcement, openings cut in the web with the depth of opening not exceeding 25% of the web depth and so located that the edges are not less than 40% of the web depth from the faceplate do not require reinforcement generally. The

length of opening is not to be greater than the web depth or 60% of the local supporting member spacing, whichever is the greater. The ends of the openings are to be equidistant from the corners of cutouts for local supporting members.

20.9.2.3 For manholes and lightening holes in double skin sections not requiring reinforcement, where openings are cut in the web and are clear of high stress areas, reinforcement of these openings is not required provided that the depth of the opening does not exceed 50% of the web depth and is so located that the edges are well clear of cutouts for the passage of local supporting members.

20.9.2.4 Manholes and lightening holes requiring reinforcement may be stiffened as required by Figure 20.9.2.4, i.e. stiffeners on members contributing to longitudinal strength are to be fitted along the free edges of the openings, parallel to the vertical and horizontal axes of the opening. Stiffeners may be omitted in one direction if the shortest axis is less than 400 mm, and in both directions if the length of both axes is less than 300 mm. Edge reinforcement may be used as an alternative to stiffeners.

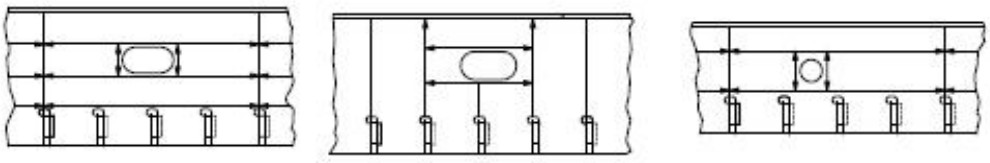

Figure 20.9.2.4 Reinforcement of manholes and lightening holes

20.9.3 Stiffeners or brackets

20.9.3.1 Requirements for stiffeners or brackets are to comply with the provisions of Section 12, Chapter 5 of this PART.

Appendix 1 DIRECT CALCULATION OF HULL STRUCTURES WITHIN THE CARGO TANK REGION

1 GENERAL REQUIREMENTS

1.1 Application

1.1.1 This Appendix applies to direct calculation and assessment of hull structures within the cargo tank region of membrane tank liquefied gas carriers required by this Chapter.

1.2 Definitions

1.2.1 Symbols

Unless otherwise specified, the following symbols in this Chapter are defined as follows:

ρ_w — density of seawater, to be taken as 1.025 t/m^3;

ρ_c —density of liquid cargo, to be taken as 0.50 t/m^3 for LNG;

ρ —density of liquid, taken as ρ_w or ρ_{LNG} as applicable;

σ_e — equivalent stress of plate element (i.e. von Mises stress), in N/mm^2, based on membrane stresses at element centroid;

R_{eH} — yield stress of material, in N/mm^2;

K — material factor, as defined in Section 3, Chapter 1 of this PART;

E — elastic modulus of material, $E = 2.06 \times 10^5$ N/mm^2 or $E = 2.06 \times 10^{11}$ N/m^2 for steel;

ν — Poisson's ratio of material, $\nu = 0.3$ for steel.

2 LOADS

2.1 General requirements

2.1.1 In the assessment of the structural strength, all load components with respect to the hull girder bending moment, internal liquid pressure and external hydrodynamic pressure and other local pressures, inertia forces due to ship's motions, structural weight as well as the weight of the insulation of cargo containment systems are to be taken into account.

2.1.2 When longitudinal bending moment, hydrodynamic pressure (external) and inertia force and added pressure heads (internal) are to be obtained by direct calculation, recognized theories and application programs are to be used for the calculation.

2.2 Static loads

2.2.1 Hull girder still water bending moment M_{sw} is covered in 2.2.2, Chapter 2 of this PART. Unless otherwise specified, loading patterns are to be considered according to Table 2.4.1 of this Appendix.

2.3 Wave loads

2.3.1 Longitudinal vertical wave bending moment

Vertical wave bending moment: $M_{w_sagging}$ (sagging) and $M_{w_hogging}$ (hogging)

$$M_{w_sagging} = k_w M_w\,(-) \qquad \text{kN·m}$$

$$M_{w_hogging} = k_w M_w\,(+) \qquad \text{kN·m}$$

where: k_w — factor, normally to be taken as 1.0;

$M_w(+)$, $M_w(-)$ – as given in 2.2.3, Chapter 2 of this PART.

2.3.2 Horizontal wave bending moment

Horizontal wave bending moment: M_H

$$M_H = \pm 84 k_w C L^2 D (C_b + 0.7) \times 10^{-3} \quad \text{kN·m} \quad \text{(positive tension port)}$$

where: k_w — as given in 2.3.1;

C — as given in 2.2.3, Chapter 2 of this PART.

2.3.3 External pressure

(1) External pressure p_{sea_side}, is the superimposition of still water pressure and hydrodynamic pressure, which can be expressed by the following equation:

$$p_{sea_side} = p_{sea_static} + p_{sea_dynamic} \quad \text{N/mm}^2 \text{ (positive inboard)}$$

p_{sea_side} will be taken as 0 if the calculated value is less than 0.

where: p_{sea_static} — still water pressure, $p_{sea_static} = 0.001\rho_w g h_s$ kN/mm²;

h_s — pressure head in still water, in m, taken as draught d in design condition;

$p_{sea_dynamic}$ — hydrodynamic pressure, $p_{sea_dynamic} = 0.001\rho_w g k_c h_{di}$ kN/mm²;

k_c— correlation factor for a specific combined load case, as given in Table 2.4.1 of this Appendix;

h_{di}— hydrodynamic pressure head at location i, in m, $h_{di}=1.36\lambda_i C_f C_w$, distributed as in Figure 2.3.3(1),

where:

λ_i — distribution factor of hydrodyn3

amic pressure head around the girth of ship at location *i,* as given in Table 2.3.3(1) or as obtained by the linear interpolation at other locations;

C_f — distribution factor of hydrodynamic pressure head along the length of the ship, to be taken as $C_f = k_{f0}$:

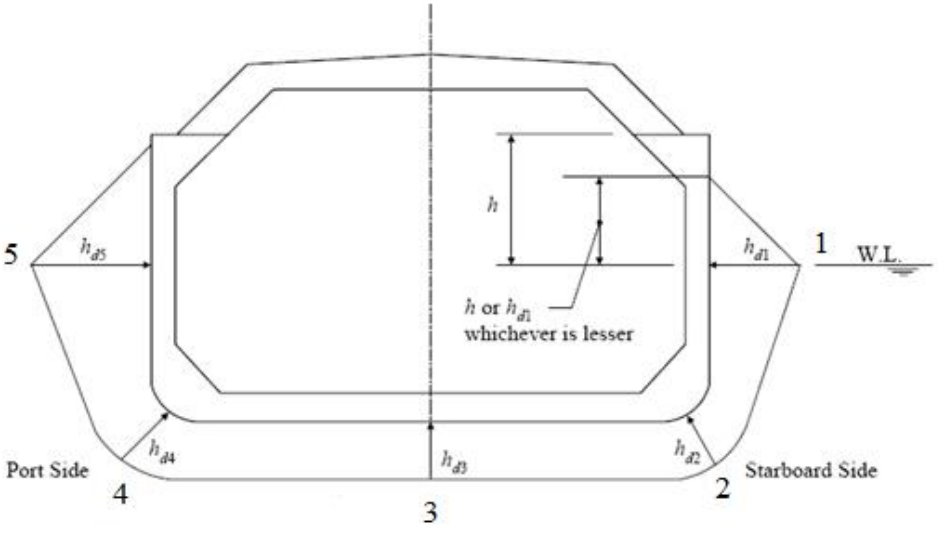
k_{f0}— factor, as given in Table 2.4.1;

θ — wave heading angle, $\theta = 0$℃ for head sea; $\theta = 90$℃ for beam sea from starboard;

C_w — wave coefficient, see coefficient C in 2.2.3.1, Chapter 2 of this PART.

Distribution factor of hydrodynamic pressure head λ_i Table 2.3.3(1)

Wave heading angle θ°	i = 1, at waterline, starboard	i = 2, at bilge, starboard	i = 3, at bottom longitudinal centerline	i = 4, at bilge, port	i = 5, at waterline, port
0° for head sea	0.750	0.300	0.300	0.300	0.750
60° for oblique sea	0.875	0.350	0.127	-0.096	-0.333
90° for beam sea	1.000	0.400	0.100	-0.200	-0.500
At any angle	$1.00 - \frac{\cos\theta}{4}$	$\frac{2}{5} - \frac{\cos\theta}{10}$	$\frac{3}{10} - \frac{\sin\theta}{5}$	$\frac{2 - 4\sin\theta + \cos\theta}{10}$	$\frac{3}{4} - \frac{5}{4}\sin\theta$

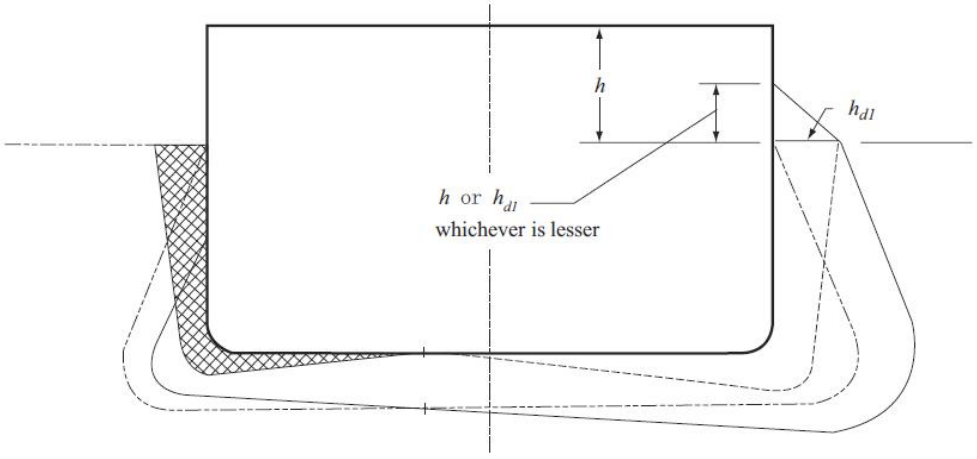


h – distance from the waterline to the highest deck of side ballast tank (lower end of trunk deck), in m.

Note: Pressure head h_{di} at waterline, starboard, is to be taken as h or $h_{di}|_{i=1}$, whichever is lesser.

Figure 2.3.3(1) Distribution of external hydrodynamic pressure

(2) Distribution of p_{sea_side}, as given in Figure 2.3.3(2).



– – – – – – – – h_d: hydrodynamic pressure head (being negative)
— - - — - - — h_s: hydrostatic pressure head in still water
———————— : total external sea pressure head
h – as given in Figure 2.3.3 (1).

Figure 2.3.3(2) Distribution of external sea combined pressure

2.3.4 Internal pressures of tanks (excluding sloshing and impact loads)

(1) Parameters of ship motions

Where data related to seakeeping analysis or model tests are not available, the equations given below may be used in calculating the parameters of ship motions:

① The pitch amplitude (positive bow up):

$$\psi = \frac{1030}{L}\left(\frac{V}{C_b}\right)^{0.25} \quad (°), \text{ but need not to be taken greater than } 10°$$

② The pitch natural period:

$$T_p = 3.5\sqrt{C_b d_i} \quad \text{s}$$

where: d_i — draught for the relevant loading conditions, in m, as given in Table 2.4.1

③ The roll amplitude (positive starboard down):

$$\phi = \phi_0 \lambda_T \quad (°), \text{ but need not to be taken greater than } 30°$$

where: ϕ_0 — basic roll amplitude,

$$\phi_0 = (1.3 - 0.025V)\{35 - 5\times10^{-6}\times10.05\times[1.06(\frac{d_i}{d}) - 0.06]LBdC_b\}$$

$$\lambda_T = \begin{cases} 0.8625+0.027T_{roll} & \text{for } T_{roll} \le 12.5 \quad \text{s} \\ 1.5375-0.027T_{roll} & \text{for } 12.5 \le T_{roll} \le 20 \quad \text{s} \\ 1 & \text{for } T_{roll} > 20 \quad \text{s} \end{cases}$$

④ The roll natural motion period:

$$T_r = \frac{2.0 r_{roll_gyr}}{\sqrt{GM}} \quad \text{s}$$

where: r_{roll_gyr} — roll radius of gyration, in m, as given in Table 2.3.4(1);
GM — metacentric height, in m, as given in Table 2.3.4(1);
d_i — same as ②.

Values of metacentric height *GM* and roll radius of gyration r_{roll_gyr}

Table 2.3.4(1)

Loading and draught	*GM*	r_{roll_gyr}
Full load	0.12B	0.35B
0.75*d*	0.18B	0.38B

⑤ Accelerations of the ship motion

Vertical acceleration: $a_v = f_v k_v a_0 g$ m/s^2, positive downward;

Longitudinal acceleration: $a_{longi} = f_l k_l a_0 g$ m/s^2, positive forward;

Transverse acceleration: $a_t = f_t k_t a_0 g$ m/s^2, positive starboard;

where: a_0 — common acceleration parameter,

$$a_0 = (1.09 + 0.029V - 0.47C_b)(\frac{2.4}{\sqrt{L}} + \frac{34}{L} - \frac{600}{L^2});$$

f_v — factor, $f_v = cos\,\theta + \frac{(1+2.4\frac{y}{B})sin\,\theta}{k_v}$;

k_v — factor, $k_v = \sqrt{1 + 0.65(5.3 - \frac{45}{L})^2(\frac{x}{L} - 0.45)^2}$;

f_l — factor, $f_l = 0.35 - 5.0(L - 200) \times 10^{-4}$;

k_l — factor, $k_l = 0.5 + \frac{8z}{L}$;

f_t — factor, $f_t = 1.27\sqrt{1 + 1.52(\frac{x}{L} - 0.45)^2}$;

k_t — factor, $k_t = 0.35 + \frac{z}{B}$;

x — longitudinal distance from the A.P. to the station considered, in m;

y — transverse distance from the centerline to the point considered, in m, positive starboard;

z — vertical distance from the waterline to the point considered, in m, positive upward.

The point considered above is taken as the centroid position of tanks.

(2) Internal pressures of tanks

Distribution p_i of internal pressures is determined by superimposing vapor pressure of liquefied gas, liquid pressure, wave-induced hydrodynamic inertia force and added pressure. For a completely filled tank, the distribution of internal pressures may be obtained from the following formula:

$$p_i = 0.001\rho_{LNG} g(z_{local_tank} + \Delta z_{local_tank} + h_{wave_induced}) + p_0 \quad \text{N/mm}^2$$

(Positive from geometric centroid of the tank toward tank boundaries)

where: p_0 — vapor pressure, determined according to the following formula:

$$p_0 = \begin{cases} p_{vp} - p_n & \text{in cargo tank, taken as 0 when the calculated value is less than 0} \\ 0 & \text{in ballast tank} \end{cases}$$

p_{vp} — maximum pressure setting on vacuum relief valve, in MPa; to be taken as not greater than 0.07 MPa;

p_n — standard design vapor pressure, taken as 0.025 MPa;

z_{local_tank} — local coordinate in vertical direction for tank boundaries measuring from the top of the tanks, as shown in Figure 2.3.4(2), in m;

Δz_{local_tank} — to be taken as follows:

a) 0 for the cargo tank and the ballast tank whose tank top extends to the upper deck or the trunk deck;

b) a distance equivalent to 2/3 of the distance from tank top to the top of the overflow (the exposed height is minimum 760 mm above freeboard deck or 450 mm above superstructure deck) for the lower tank whose tank top does not extend to the upper deck;

$h_{wave_induced}$ — wave-induced internal pressure head, including inertial force and added pressure head, determined as follows:

$$h_{wave_induced} = k_c(z_{tank_local}\frac{a_i}{g} + \Delta h_i)$$

where:

k_c —internal pressures, see Table 2.4.1;

a_i — effective resultant acceleration at the point considered, and may be approximated by:

$$a_i = 0.71C_{dp}[w_v a_v + w_{longi}(\frac{l}{h})a_{longi} + w_t(\frac{b}{h})a_t] \quad \text{m/s}^2$$

where:

C_{dp} — as given in Table 2.3.4(2);

a_v, a_{longi}, a_t — as given in 2.3.4(1)⑤;

w_v, w_{longi}, w_t — weighted coefficients, as specified in Table 2.4.1;

l — length of the tank, in m;

b — width of the tank, in m;

h — height of the tank, in m;

Δh_i — added pressure head due to pitch and roll motions, in m, may be calculated as follows:

a) for bow down and starboard down ($\psi_e < 0, \phi_e > 0$):

$$\Delta h_i = x_{\tan k_local} \sin(-\psi_e) + C_{ru}(y_{\tan k_local_e} \sin\phi_e \cos\psi_e + z_{\tan k_local_e} \cos\psi_e \cos\phi_e - z_{\tan k_local})$$

where:

$x_{\tan k_local}$ — local coordinate for the point considered with respect to length as in Figure 2.3.4(2), in m;

$y_{\tan k_local}$ — local coordinate for the point considered with respect to width, as in Figure 2.3.4(2), in m;

$z_{\tan k_local}$ — local coordinate for the point considered with respect to height, as in Figure 2.3.4(2), in m;

$y_{\tan k_local_e}$ — taken as $b - y_{\tan k_local}$;

$z_{\tan k_local_e}$ — taken as $z_{\tan k_local}$;

b) for bow up and starboard up ($\psi_e > 0, \phi_e < 0$):

$$\Delta h_i = (l - x_{\tan k_local}) \sin\psi_e + C_{ru}[y_{\tan k_local_e} \sin(-\phi_e) \cos\psi_e + z_{\tan k_local_e} \cos\psi_e \cos\phi_e - z_{\tan k_local}]$$

where:

$y_{\tan k_local_e}$ — taken as $y_{\tan k_local} - \delta_b$

$z_{\tan k_local_e}$ — taken as $z_{\tan k_local} - \delta_h$

δ_b , δ_h — the local coordinates for the point considered with respect to adjusted values, in m, as shown in Figure 2.3.4(2);

C_{ru} — as in Figure 2.3.4(2);

C_ψ , C_ϕ — weighted coefficients, as in Table 2.4.1;

ψ_e — taken as $0.71_C_\psi\psi$;

ϕ_e — taken as $0.71C_\phi\phi$;

ψ and ϕ — pitch and roll amplitudes, as given in 2.3.4(1).

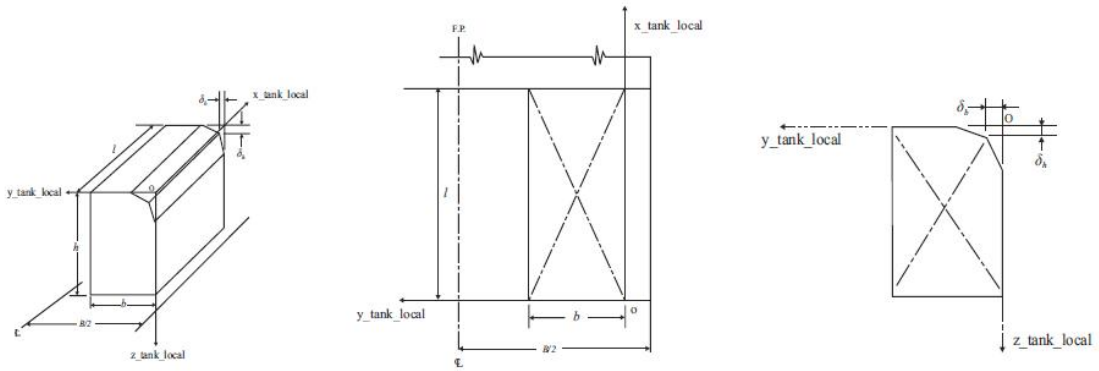


Figure 2.3.4(2) Local coordinates and geometry of tank

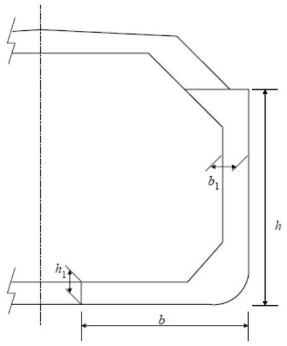
Definition of tank shape and associated coefficients – as given in Table 2.3.4(2).

Tank shape and associated coefficients **Table 2.3.4(2)**

Applicable conditions	Tank shape	C_{dp}	C_{ru}
$\frac{b}{b_1} \le 3.0$ or $\frac{h}{h_1} \le 3.0$	Rectangular tank	1.0	1.0
$\frac{b}{b_1} \ge 5.0$ or $\frac{h}{h_1} \ge 5.0$	J-shaped tank	0.7	1.0
$3.0 < \min\left\{\frac{b}{b_1}, \frac{h}{h_1}\right\} < 5.0$	Other tank	$1.0 - 0.15\left\{\min\left\{\frac{b_1}{b}, \frac{h}{h_1}\right\} - 3.0\right\}$	1.0

where: b – extreme breadth of the tank considered, in m;
b_1 – least breadth of wing tank part of the tank considered, in m;
h – extreme height of the tank considered, in m;
h_1 – least height of double bottom part of the tank considered, in m;
the above symbols are as shown in the figure on the right.



2.4 Combined load cases

2.4.1 The design load cases, to which the strength assessment by direct calculation as given in this Appendix applies, consist of conventional cases, accidental cases (see Table 2.4.1). Where more critical cases likely to be encountered are not covered in the above cases, if any, they are to be additionally analyzed.

2.4.2 In accordance with the principle requirements of loading and strength criteria, hull responses under static loads (S) and dynamic + static loads (S+D) are to be considered in a comprehensive manner. The weight of the insulation of cargo containment system is also to be considered. In addition, "a collision force acting on the tank corresponding to one half the weight of the tank and cargo in the forward direction" the ship is to withstand, as required in CCS Rules for Construction and Equipment of Ships Carrying Liquefied Gases in Bulk is to be considered as an accidental case and listed in Table 2.4.1.

2.4.3 For the longitudinal vertical bending moment of hull girders, the resultant bending moment may be considered as follows:

$$M_V(+) = M_{sw}(+) + k_{cV} M_{w_hogging} \qquad \text{in hogging condition}$$

$$M_V(-) = M_{sw}(-) + k_{cV} M_{w_sagging} \qquad \text{in sagging condition}$$

where: M_{sw} — as given in 2.2;

$M_{w_sagging}$ and $M_{w_hogging}$ — as given in 2.3;

k_{cV} — coefficient of hull girder vertical wave bending moment applied on both ends of the model, as in Table 2.4.1.

2.4.4 Other loads as given in Table 2.4.1 are to be multiplied by relevant load factors for combined load cases.

2.4.5 The length of the model considered for load patterns as shown in Table 2.4.1 is equal to three complete cargo tanks.

2.4.6 The distribution of resultant external pressure heads at different locations of one hull girder section is shown in Figure 2.3.3(2).

2.4.7 The bending moment of end planes of the FE model may be corrected in accordance with the simple beam theory. The bending moment applied on end planes of the model is so adjusted that the resultant vertical and horizontal bending moment applied on the mid-point of the middle tank of the 3-tank model is equal to the target value.

Load cases for cargo tank FEM analysis of membrane tank liquefied gas carriers **Table 2.4.1**

No.	Load pattern	Vertical B.M. k_{cV}	Horizontal B.M. k_{cH}	External pressures		Internal pressures								Wave heading angles and ship motions

3 STRUCTURAL MODEL

3.1 General requirements

3.1.1 Except for buckling assessment, the dimension of finite element models covered in this Appendix are taken as the scantlings (e.g. thickness, length) specified in the drawings, namely the as-built scantlings. Where net scantlings are used, permissible stresses are to be considered otherwise.

3.2 Structural modeling

3.2.1 The length of the model is to cover the three cargo tank lengths (No.2, No.3 and No.4 tanks and/or No.3, No.4 and No.5 tanks) in the midship cargo tank region, and the length of the middle tank is to be the greatest among the three tanks, as shown in Figure 3.2.1. The transverse extent is to be the entire breadth of the ship. The vertical extent is to be the entire moulded depth. The change of moulded line of ship side in longitudinal direction is not to be taken into account.

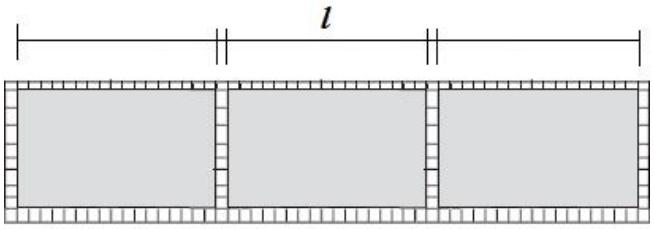

Figure 3.2.1 Extent of finite element modeling of cargo tanks

3.2.2 All primary longitudinal and transverse structural members of the hull are to be represented in the model, including bottom shell, side shell, deck plating (including trunk deck), inner deck, inner bottom, inner hull, hopper and inner hull slope plating, double bottom girders, deck girders, stringers (continuously or partially arranged) in double side tanks and longitudinals continuously arranged on such plating as well as primary transverse supporting members such as transverse web frames, deck transverses, double bottom floors, and cofferdam transverse bulkheads. In addition, all plating and stiffeners, including web stiffeners, on these structural members are to be modeled.

3.2.3 All main plating is to be simulated by plate elements. Stiffeners on the plating are to be simulated by beam elements and the attached plates are to be considered for the properties of bending (eccentricity is required in the program.).

3.2.4 The plate element mesh is to follow the stiffening system of the structure as far as practical, properly representing the geometrical characteristics of actual plate panels between stiffeners. The plate element mesh is to satisfy the following requirements:

(1) transversely and vertically, one element between every longitudinal stiffener;

(2) longitudinally, one element between every frame space, and the element length is not to be greater than two longitudinal spaces;

(3) for webs of primary supporting members (including transverse web frames, double bottom girders and floors, and vertical diaphragm and horizontal stringers on bulkheads), one element between every web stiffener, and at least three elements over the depth of these members.

3.2.5 In general, web frames in double side tanks, deck transverses and small openings in double bottom floors may be represented by deleting corresponding elements. For large (web) openings of web frames in side tanks and deck transverses, the meshing of edges and boundaries is to be fine enough to represent the curvature of the edges of the openings.

3.2.6 Normally quad plate elements are to be used and the use of triangular plate elements is to be kept to a minimum. The aspect ratio of the quad plate elements is in general not to exceed three. Where possible, the aspect ratio of plate elements in areas, where high stress or a high stress gradient is likely to occur, is to be kept close to one and the use of triangular elements is to be avoided.

3.3 Boundary conditions

3.3.1 The boundary conditions to be applied at the ends of the cargo tank FE model are as follows and also given in Table 3.3.1:

(1) the aft end of the model is assumed to be kept plane, an independent point is set in way of the neutral axis of the section, other nodal points of the end plane are linked to the independent point, and the bending moment is applied on the independent point;

(2) the fore end of the model is assumed to be kept plane, an independent point is set in way of the neutral axis of the section, other nodal points of the end plane are linked to the independent point, and the bending moment is applied on the independent point.

Boundary constraints at model ends **Table 3.3.1**

Location	Translation			Rotation		
	δ_x	δ_y	δ_z	θ_x	θ_y	θ_z
Aft end						
Aft end (all longitudinal elements)	RL	–	–	–	RL	RL
Independent point at aft end, see Figure 3.3.2	FIX	–	–	–	$M_{v\text{-}end}$	$M_{h\text{-}end}$
Deck, inner bottom and outer shell	–	Springs	–	–	–	–
Side shell, and inner hull	–	–	Springs	–	–	–
Fore end						
Fore end (all longitudinal elements)	RL	–	–	–	RL	RL
Independent point at fore end, see Figure 3.3.2	–	–	–	–	$M_{v\text{-}end}$	$M_{h\text{-}end}$
Deck, inner bottom and outer shell	–	Springs	–	–	–	–
Side shell, and inner hull	–	–	Springs	–	–	–

where:

— – no constraint applied (free);

M_{h-end} – total vertical bending moment applied on model ends;

M_{v-end} – total horizontal bending moment applied on model ends;

δ_x – constraint of displacement along longitudinal axis;

δ_y – constraint of displacement along transverse axis;

δ_z – constraint of displacement along vertical axis;

θ_x – constraint of rotation about longitudinal axis;

θ_y – constraint of rotation about transverse axis;

θ_z – constraint of rotation about vertical axis.

3.3.2 The fore and aft end planes of the model are to be subject to end bending moment and constrained in degree of freedom. In addition, spring elements are to be arranged vertically and horizontally to precisely represent the stiffening provided to both ends of the cargo tank model by the fore and aft hull structures adjacent to the model. Ground spring elements, i.e. spring elements with one end constrained in all 6 degrees of freedom, with stiffness in global *y* degree of freedom are to be applied to the grid points along inner deck and trunk deck, inner bottom and bottom shell. Ground spring elements with stiffness in global *z* degree of freedom are to be applied to the grid points along the vertical part of the side shells and inner hulls as shown in Figure 3.3.2.

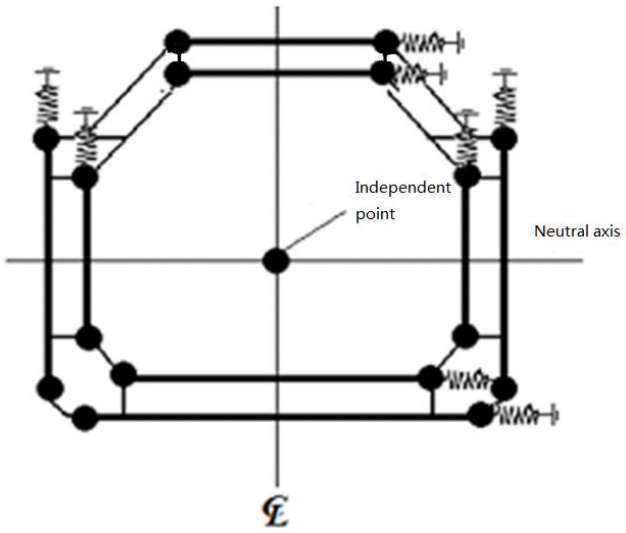

Figure 3.3.2 Boundary condition of finite element modeling

3.3.3 The stiffness, c, of individual spring elements for each structural member, to be applied at each end of the cargo tank model, is given by:

$$c = \left(\frac{E}{1+\nu}\right)\frac{A_s}{l_{tk}n} = 0.77\frac{AE}{l_{tk}n} \quad \text{N/mm}$$

where: A_s — shearing area of the individual structural member under consideration, in mm^2, i.e. plating of deck, trunk deck, inner bottom, bottom shell, side shell, or inner hull longitudinal bulkheads, see Figures 3.3.3(1) and (2) for details;

l_{tk} — length of cargo tank, between bulkheads of the middle tank of the FE model, in mm;

n — number of nodal points to which the spring elements are applied to the structural member under consideration.

Shear areas to be considered in the calculation of spring stiffness **Table 3.3.3(1)**

Vertical springs		
	Side:	Area of side shell plating, including bilge strake
	Inner hull longitudinal bulkheads:	Area of inner hull plating, including hopper sloped plate and double bottom side girder in way
	Trunk deck:	Area of sloped parts of trunk deck and inner deck plating
	Note: Where part of the structural member is not vertical, the area is to be calculated using the projected area in the vertical direction	

Shear areas to be considered in the calculation of spring stiffness **Table 3.3.3(2)**

Horizontal springs		
	Trunk deck:	Area of sloped parts of trunk deck and inner deck plating, including horizontal stringer and upper deck in way
	Inner bottom:	Area of inner bottom plating, including hopper sloped plate and horizontal stringer in way
	Bottom shell:	Area of bottom shell, plating, including bilge strake
	Note: Where part of the structural member is not horizontal, the area is to be calculated using the projected area in the horizontal direction	

4 RESULT EVALUATION

4.1 General requirements

4.1.1 The evaluation is to cover the middle tank of the three cargo tanks FE model, including the regions forward of the fore end of its forward bulkhead and aft of the aft end of its aft bulkhead up to the extent of one or two frames into the adjacent tanks, as shown in Figure 4.1.1.

4.1.2 Stress level and panel buckling capability of longitudinal structural members, primary supporting members and transverse bulkheads within the regions considered are to be verified. Particular attention is to be given to the scantlings and the assessment of required strengthening in way of transverse bulkheads against hull girder shear load, the intersection of hopper and inner hull, double side stringers, and double bottom girders and floors.

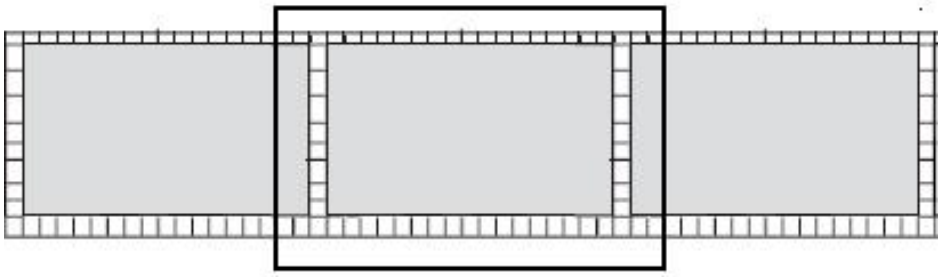

Figure 4.1.1 Strength evaluation region

4.1.3 In general, the strength criteria for the same structural member are different in static load cases and in static + dynamic load cases. In addition, special restrictions are imposed on permissible stresses for some members to avoid excessive stress strain of the insulation of cargo containment system. Strength check in respect to "the forward collision force equal to a half of the weight of cargo tank and cargo" is differently specified in this Section. For strength assessment, attention is to be drawn to the above-mentioned point.

4.2 Yield assessment

4.2.1 Yield assessment criteria for structural members in any condition to be checked are shown in Table 4.2.1.

Yield strength assessment criteria **Table 4.2.1**

Structural member	Yield utilisation factor and permissible stress restriction
Hull girder longitudinal member plating and bulkhead plating	
Bottom shell, bilge plate, side shell, upper deck, trunk deck slope plating, trunk deck plating, double bottom girders, side stringers, transverse bulkhead plating etc.	1) Conventional condition: $\lambda_y \leq 1.0$, for bottom shell and double bottom girders $\lambda_y \leq 0.9$, for other structural members. 2) Accidental ~~design~~ condition: $\lambda_y \leq 1.00$
Structures in direct contact with secondary barriers, e.g. inner bottom plating, hopper slope plating, inner hull plating, inner hull slope plating, inner deck slope plating, inner deck plating etc.	The following criteria are to be satisfied for any loading condition: $\lambda_y \leq 0.90$
Primary supporting member plating	
Primary transverse supporting structures, e.g. double bottom floors, side transverse diaphragms, deck transverses, bulkhead platform of double plane transverse bulkheads and vertical longitudinal diaphragms etc.	$\lambda_y \leq 0.75$
Notes: (1) Yield utilisation factor $\lambda_y = \frac{\sigma_e}{R_{eH}}$ for plate element; $\lambda_y = \frac{\sigma_{rod}}{R_{eH}}$, for face plate of primary supporting members modelled by rod element or beam element.	

4.2.2 Yield deformation is to be so controlled that maximum relative deformation of the plating between stiffeners of all hull panels (including inner bottom plating, hopper slope plating, inner hull plating, inner hull slope plating, inner deck plating and inner deck top plating as well as transverse bulkhead plating)/plating of unstiffened panels regarding periphery of insulations is generally not to be greater than 4.0 mm.

4.3 Buckling assessment

4.3.1 The buckling assessment criteria for structural plate and girder web plate panels in any check condition are shown in Table 4.3.1. And for panels of plates in direct contact with the insulation (secondary barrier system) of cargo containment system, e.g. inner bottom, inner hull, wing tank slope plating, inner deck and transverse bulkhead plates, deformation is to be controlled within the range of elastic buckling so that the function of insulation of cargo containment system will not be damaged.

4.3.2 Bucking assessment is to be based on elementary plate panels (EPP). An EPP is the unstiffened and unstrengthened part of the plating in the area except for the boundary ($a \times b$). Only rectangular panels are considered in the buckling calculation of panels, as shown in Figure 4.3.2.

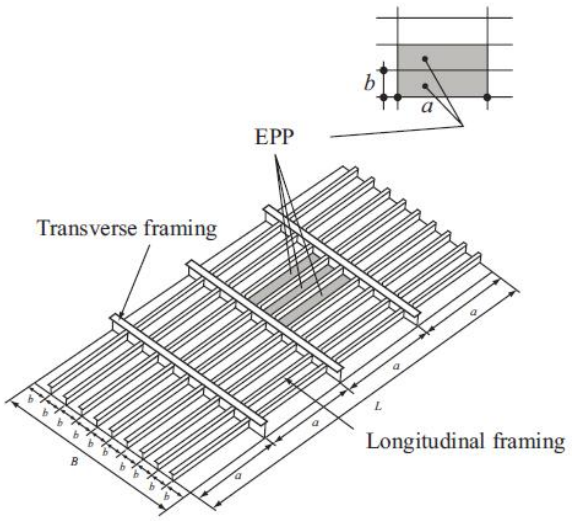

Figure 4.3.2 Elementary plate panels in buckling assessment

4.3.3 Panel bucking calculation approaches and criteria specified in this Appendix are based on elastic buckling. Other theories, calculation programs and assessment criteria are to be agreed by CCS.

Buckling assessment criteria **Table 4.3.1**

Structural member	Buckling safety factor
Double hull plating and bulkhead plating	
Stiffening plate panels under lateral loads, e.g. bilge plating, side shell plating, upper deck, trunk deck slope plating, trunk deck plating, inner bottom plating, inner hull plating, inner hull slope plating, inner deck slope plating, inner deck plating, transverse bulkhead plating etc.	$\lambda \geq 1.0$
Bottom plate, hopper slope plating, the outermost double bottom side girders	$\lambda \geq 0.8$
Primary member plating	
Primary supporting members, e.g. double bottom girders (except for the outermost side girders), double bottom floors, side stringers, side transverse diaphragms, deck girders, deck transverses, bulkhead platform of double plane transverse bulkheads and vertical longitudinal diaphragms etc.	$\lambda \geq 1.1$

4.3.4 Panel buckling is to be based on the "net thickness method". In calculation of critical buckling stress, plating thickness is to be taken as the calculated net thickness obtained from deducting the Standard Thickness Deduction, as given in Table 4.3.4, from the as-built thickness.

Standard thickness deduction **Table 4.3.4**

Location	Standard thickness deduction t_c (mm)
Structural members forming ballast tank boundary and located in ballast tanks, e.g. bottom plating, side shell plating, upper deck, inner bottom plating, hopper slope plating, inner hull plating, inner hull slope plating, transverse bulkheads (except for double plane transverse bulkhead), double bottom floors, double bottom girders and side stringers, side transverse diaphragms etc.	1.5

Location	Standard thickness deduction t_c (mm)
Other structural members	1.0

4.3.5 The combined interaction of uni-axial and bi-axial compressive stresses and shear stresses are to be considered in the buckling calculation.

4.3.6 Panel buckling calculation approaches may be referred to Section 5, Chapter 1 of this PART.

4.4 Fine mesh model and strength assessment

4.4.1 For an accurate and clear observation of stress level and distribution at local areas of stress concentration, fine mesh analysis and strength assessment are to be further carried out for the following critical locations:

(1) the connection of lower knuckle joints of hopper slope plating to inner bottom plating, upper knuckle joints to inner hull longitudinal bulkhead in way of transverse web frames, as shown in Figure 4.4.1(1);

(2) the connection of lower knuckle joints of inner hull slope plating to side stringers in way of transverse web frames, as shown in Figure 4.4.1(2);

(3) the connection of double side stringers to transverse bulkheads, as shown in Figure 4.4.1(3);

(4) the connection of double bottom girders to transverse bulkheads, as shown in Figure 4.4.1(4);

(5) double deck girders in way of the connection of transverse bulkheads to inner decks, as shown in Figure 4.4.1(5);

(6) large openings in transverse web frames, double bottom girders, double deck girders, double transverse bulkhead stringers and vertical diaphragms, in case higher stress is identified in the yield assessment of coarse mesh model.

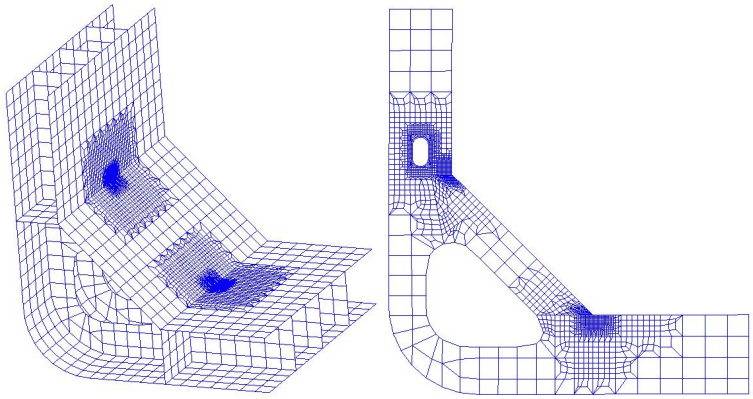

Figure 4.4.1(1) Lower and upper knuckle joints of hopper slope plating

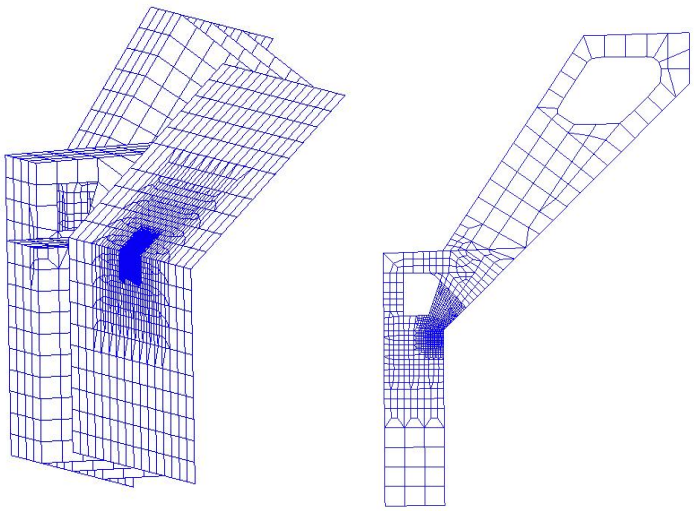

Figure 4.4.1(2) Connection of lower knuckle joints of inner hull slope plating to side stringers

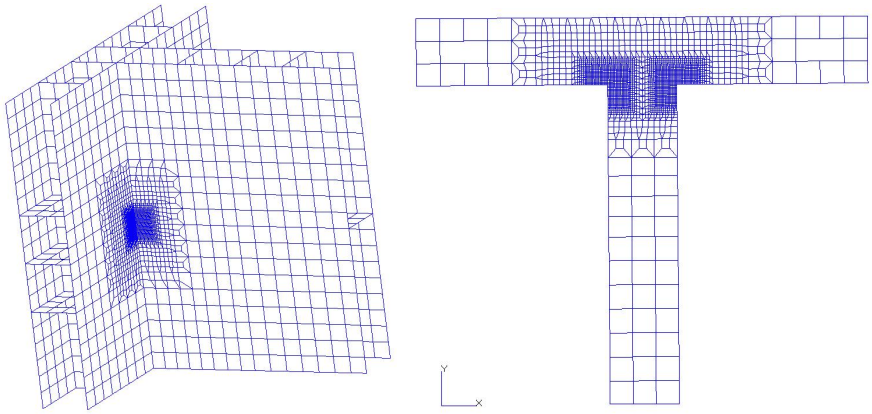

Figure 4.4.1(3) Connection of double side stringers to transverse bulkheads

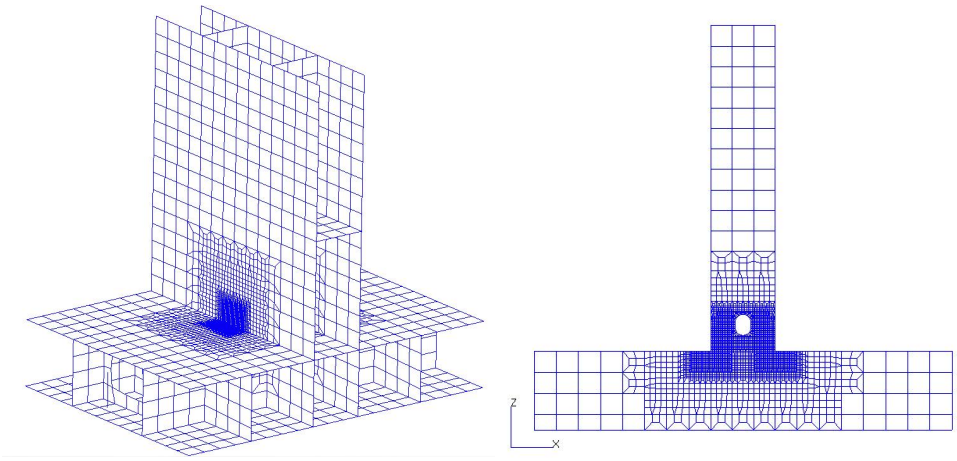

Figure 4.4.1(4) Connection of double bottom girders to transverse bulkheads

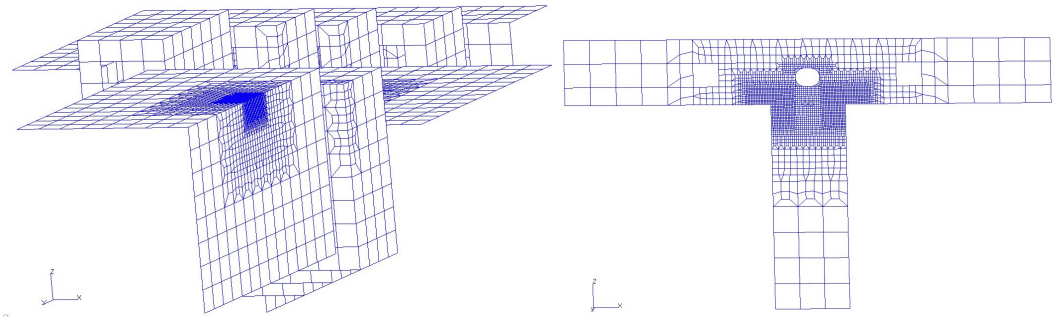

Figure 4.4.1(5) Double deck girders in way of the connection of transverse bulkheads to inner decks

4.4.2 The fine mesh analysis may be carried out by means of a separate local finite element model with fine mesh zones, in conjunction with the boundary conditions obtained from the cargo tank model, or by incorporating fine mesh zones into the cargo tank model.

4.4.3 The extent of the local finite element models is to be such that the calculated stresses at the areas of interest (i.e. areas of stress concentration under investigation) are not significantly affected by the imposed boundary conditions and application of loads. The boundary of the fine mesh model is to coincide with primary members, such as girders, stringers and floors, in the cargo tank model.

4.4.4 The mesh size in the fine mesh zones is not to be greater than 50 mm × 50 mm. In general, the extent of the fine mesh zone is not to be less than 10 elements in all directions from the area under investigation.

4.4.5 All plating within the fine mesh zone is to be represented by shell elements. A smooth transition of mesh density is to be maintained. The aspect ratio of elements within the fine mesh zone is to be kept as

close to 1 as possible. Variation of mesh density within the fine mesh zone and the use of triangular elements are to be avoided. In all cases, the elements are to have an aspect ratio not exceeding 3. Distorted elements, with element corner angle less than 60° or greater than 120°, are to be avoided. Stiffeners inside the fine mesh zone are to be modeled using shell elements. Stiffeners outside the fine mesh zone may be modeled using beam elements.

4.4.6 Where a FE sub-model is used for transverse web frames, the model is to have an extent of at least 1 + 1 web frame spaces, i.e. one web frame space extending either side of the transverse web frame under investigation. The transverse web frames forward and aft of the web frame under investigation need not be included in the sub model. In addition, the full depth and full breadth of the ship are to be modeled.

4.4.7 For transverse bulkhead stringers, due to the structural interaction between the transverse bulkhead, horizontal stringers, web frames, deck and bottom, it is recommended that the FE sub-model represents a full section of the hull. Longitudinally, the ends of the model are at least to be extended one web frame space beyond the areas that require investigation. The full breadth and depth of the ship should be modeled.

4.4.8 The fine mesh detailed stress analysis is to be carried out for the design load cases specified in this Section.

4.4.9 Where a separate local finite element model is used for the fine mesh detailed stress analysis, the nodal displacements from the cargo tank model are to be applied to the corresponding boundary nodes on the local model as prescribed displacements. Alternatively, equivalent nodal forces from the cargo tank model may be applied to the boundary nodes.

4.4.10 Where there are nodes on the local model boundaries which are not coincident with the nodal points on the cargo tank model, it is acceptable to impose prescribed displacements on these nodes using multi-point constraints. The use of linear multi-point constraint equations connecting two neighboring coincident nodes is considered sufficient.

4.4.11 All local loads in way of the structure represented by the separate local finite element model are to be applied to the model.

4.4.12 Stress check criteria and approaches for fine mesh analysis are given in Table 4.4.12 and the description thereto.

Maximum permissible membrane stresses for fine mesh analysis **Table 4.4.12**

Element stress	Yield utilisation factor
Element not adjacent to weld	$\lambda_y \leq 1.7$
Element adjacent to weld	$\lambda_y \leq 1.5$

where: (1) λ_y — yield utilisation factor

$= \frac{K\sigma_e}{235}$, for plate element

(2) Where the von Mises stress of the elements in the cargo tank FE model in way of the area under investigation by fine mesh exceeds its permissible value specified in Table 4.2.1, average von Mises stress, obtained from the fine mesh analysis, calculated over an area equivalent to the mesh size of the cargo tank finite element model is to be less than the permissible value specified in Table 4.4.12.

(3) The maximum permissible stresses are based on the mesh size of 50 mm × 50 mm as specified in 4.4.4. Where a smaller mesh size is used, assessment may be carried out by using stress averaging method, see relevant requirements of 2.7.9, Appendix 2, Chapter 7 of this PART.

(4) The yield utilisation factor may be increased by 1.3 times for accidental conditions.

APPENDIX 2 STRUCTURAL STRENGTH ASSESSMENT OF HULL AND PUMP TOWER UNDER SLOSHING LOADS

1 GENERAL PROVISIONS

1.1 Application

1.1.1 This Appendix specifies the calculation of sloshing loads of membrane tank liquefied gas carriers, the assessment requirements in respect of the hull and pump tower structure of cargo tank region under sloshing loads and the requirements for vibration evaluation of pump tower structure.

1.1.2 Unless otherwise specified in this Appendix, the calculation methods of sloshing loads are to comply with relevant requirements of CCS Guidelines for Assessment of Sloshing Loads and Structural Scantling of Tanks.

1.1.3 Cargo tanks without partially filled conditions, i.e. filling height less than 5%h or greater than 95%h (where h is defined in Table 1.2.3 of this Appendix) may be exempted from the requirements of Sections 3 and 4 of this Appendix.

1.2 Target tank and its structural configuration

1.2.1 For the sloshing load calculation and the strength assessment of pump tower structure, the No.2 cargo tank close to the bow is to be taken as the target tank. Where it is proposed by the owner to carry out assessment of other cargo tanks, they are to be taken as additional target tanks for assessment after approval by CCS.

1.2.2 The terms of main structural configurations of cargo tanks are as shown in Figure 1.2.2.

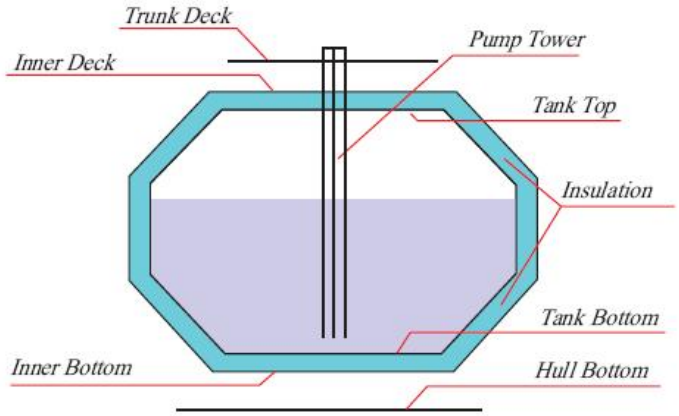

Figure 1.2.2 Terms of structural configurations of cargo tanks

1.2.3 The geometry of cargo tanks is as shown in Figure 1.2.3 and the basic parameters are defined in Table 1.2.3.

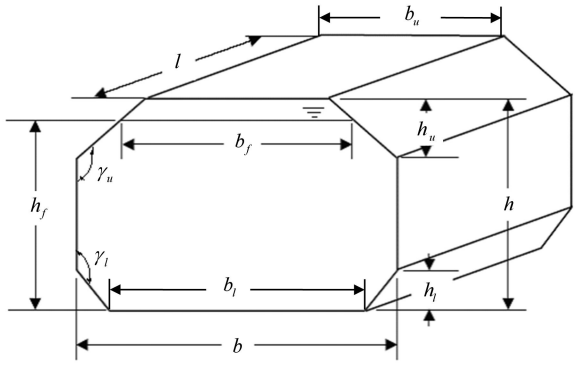

Figure 1.2.3 Main geometric parameters of cargo tanks

Definitions of geometric parameters of cargo tanks **Table 1.2.3**

No.	Variable	Definition	Unit
1	l	Length	m
2	b	Breadth	m
3	b_u	Breadth of tank top	m
4	b_l	Breadth of tank bottom	m
5	h	Depth	m
6	h_f	Filling height	m
7	b_f	Surface breadth at corresponding filling height	m
8	h_u	Upper chamfer height	m
9	γ_u	Upper chamfer angle	deg
10	h_l	Lower chamfer height	m
11	γ_l	Lower chamfer angle	deg

1.3 Definitions of parameters

1.3.1 In addition to the provisions of this Appendix, other parameters and symbols of this Appendix are defined in Section 1 and Appendix 1 of this Chapter.

1.3.2 The directions and terms of ship motions in six degrees of freedom are defined in Table 1.3.2.

Directions and definitions of ship motion in six degrees of freedom **Table 1.3.2**

Direction	Symbol	Ship motion	Displacement		Velocity		Acceleration	
			Symbol	Unit	Symbol	Unit	Symbol	Unit
X axis	ξ_1	Surge	ξ_1	m	ξ'_1	m/s	ξ''_1	m/s^2
	θ_1	Roll	θ_1	rad	θ'_1	rad/s	θ''_1	rad/s^2
Y axis	ξ_2	Sway	ξ_2	m	ξ'_2	m/s	ξ''_2	m/s^2
	θ_2	Pitch	θ_2	rad	θ'_2	rad/s	θ''_2	rad/s^2
Z axis	ξ_3	Heave	ξ_3	m	ξ'_3	m/s	ξ''_3	m/s^2
	θ_3	Yaw	θ_3	rad	θ'_3	rad/s	θ''_3	rad/s^2

2 CALCULATION OF SLOSHING LOADS

2.1 General requirements

2.1.1 This Section specifies the calculation methods of loads (including quasi-static loads, dynamic loads and impact loads) induced by free movement of the tank liquids as a result of ship motion.

2.1.2 The result of sloshing model test may be treated as sloshing design load subject to approval of CCS.

2.2 Sloshing motion levels

2.2.1 Sloshing motion levels are defined as follows:

(1) Level 1 is a static or quasi-static process. The loads due to sloshing motion at this level are mainly static loads and the dynamic motion loads may be neglected.

(2) Level 2 is a dynamic and non-magnification process of sloshing motion. The loads due to sloshing motion at this level include static and dynamic loads, but the latter have not involved the impact loads.

(3) Level 3 is a dynamic and magnification process of sloshing motion. The loads due to sloshing motion at this level include static and dynamic loads where the latter are the main loads involving impact loads.

2.2.2 Criteria for judging sloshing motion levels are as follows:

(1) Where the tank size is within the range of l <0.13L and b_f<0.56B, and the difference between natural period of tank motion and natural period of hull motion is beyond ±20%, level 1 sloshing motion is considered.

(2) Where the tank size is within the range of l <0.13L and b_f<0.56B, and the difference between natural period of tank motion and natural period of hull motion is within ±20%, or where the tank size is within the range of l ≥0.13L and b_f ≥0.56B, and the difference between natural period of tank motion and natural period of hull motion is beyond ±20%, level 2 sloshing motion is considered.

(3) Where the tank size is within the range of l ≥0.13L and b_f ≥0.56B, and the difference between tank frequency and hull natural frequency is within ±20%, level 1, level 3 sloshing motion is considered.

2.3 Loading conditions

2.3.1 The loading conditions related to the scantling assessment of hull structural members of cargo tank region, the direct calculations of cargo tanks and the assessment of structural strength of pump tower are given in Table 2.3.1.

2.3.2 For calculation required for scantling of hull structural members of cargo tank region under sloshing loads and the structural strength assessment of pump tower, the full load condition and ballast condition given in Table 2.3.1 are to be taken.

2.3.3 For FE analysis of hull structural members of cargo tank region under sloshing loads, the sloshing condition in Table 2.3.1 is to be taken.

Loading conditions **Table 2.3.1**

No.	Conditions	Draught	k	GM
1	Full load condition	d	k=0.35B	GM=0.12B
2	Ballast condition	Ballast draught at arrival	k=0.45B	GM=0.33B
3	Sloshing condition	2/3d	k=0.39B	GM=0.24B

where: k — roll radius, in m;

GM — metacentric height, in m, considering free surface correction.

2.4 Natural period of hull and tank motion

2.4.1 Based on Table 2.3.1, the hull pitch period T_p and hull roll period T_r are calculated respectively in accordance with 2.3.4, Appendix 1 of this Chapter.

2.4.2 The period of longitudinal motion T_x is calculated in accordance with the following formula:

$$T_x = \sqrt{\frac{4\pi l}{g\tanh\left(\frac{\pi h_f}{l}\right)}} \quad \text{s}$$

2.4.3 The period of transverse motion T_y is calculated in accordance with the following formula:

$$T_y = \sqrt{\frac{4\pi b_f}{g\tanh\left(\frac{\pi h_f}{b_f}\right)}} \quad \text{s}$$

2.5 Filling heights under consideration

2.5.1 All the filling heights in the loading manual are to be used as the filling heights under consideration for analysis of sloshing loads.

2.5.2 Where additional loading is required by the owner, detailed data is to be provided as the additional filling height under consideration for analysis of sloshing loads.

2.5.3 In addition to the above requirements for filling heights under consideration, four standard heights under consideration of 5%h, 10%h, 70%h and 95%h are also to be taken into account for the calculation of structural strength of pump tower.

2.6 Level 1 sloshing loads

2.6.1 Level 1 sloshing pressure acting on the tank boundary due to the still water pressure of cargo and linear variation of surface is to be calculated according to relevant provisions of Section 2 of CCS Guidelines for Assessment of Sloshing Loads and Structural Scantling of Tanks.

2.7 Level 2 sloshing loads

2.7.1 Level 2 sloshing pressure P_2 acting on the tank boundary due to the still water pressure of cargo and sloshing motion is to be calculated according to relevant provisions of Section 2 of CCS Guidelines for Assessment of Sloshing Loads and Structural Scantling of Tanks.

2.8 Level 3 sloshing impact loads

2.8.1 This paragraph gives rule calculation method for level 3 sloshing impact loads.

2.8.2 The impact pressure in way of inner hull slope plating:

$$\text{Transverse motion:} \quad P_3 = \frac{168\rho g}{B}\left(\frac{b_f}{B} - 0.3\right)GM^{1.5}\sin^2\gamma_u C_{t_imp1} \quad \text{kN/m}^2$$

where: γ_u — angle between the plating considered and the vertical plane;

$C_{t_imp1} = C_t$, h_f is to be taken as $0.7(h - h_u)$ in calculation of C_t;

$C_t = 0.9y_{01} / [1 + 9(1 - y_0)^2]$, to be taken not less than 0.25;

$y_0 = T_y / T_r$;

$$y_{01} = \begin{cases} y_0 & y_0 \le 1 \\ 1 / y_0 & y_0 > 1 \end{cases}$$

2.8.3 The impact pressure in way of tank top:

Longitudinal motion: $P_3 = 1.24\rho g(\frac{220l}{L} - 7.5)C_{l_imp2}$ kN/m^2

Transverse motion: $P_3 = \frac{164\rho g}{B}(\frac{b_f}{B} - 0.3)GM^{1.5}\sin^2\gamma_u C_{t_imp1}$ kN/m^2

where: $C_{l_imp2} = C_l$, h_f is to be taken as $0.7h$ in calculation of C_t;

$C_l = 0.9x_{01} / [1 + 9(1 - x_0)^2]$, to be taken not less than 0.25;

$x_0 = T_x / T_p$;

$$x_{01} = \begin{cases} x_0 & x_0 \le 1 \\ 1 / x_0 & x_0 > 1 \end{cases};$$

γ_u — angle between the plating considered and the vertical plane.

2.8.4 The area of tank top under the impact pressure is as shown in Figure 2.8.4.

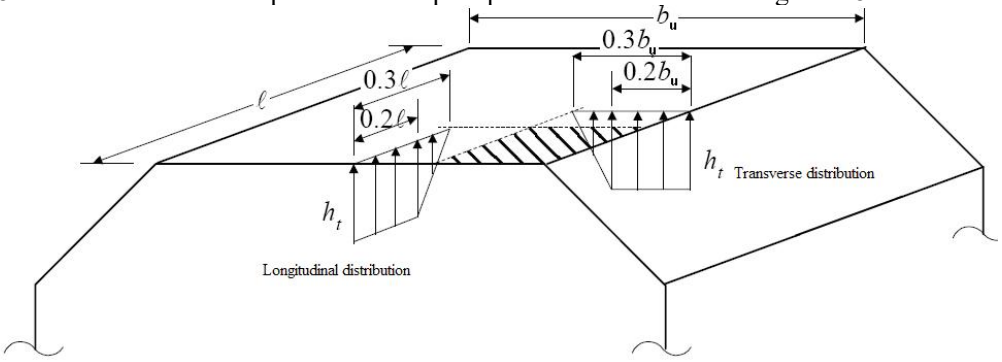

Figure 2.8.4 Area of tank top under the impact pressure

2.8.5 The impact pressure in way of the lower part of tank

(1) Within an area of $0.2b_f$ or $0.2l$ in height from the inner bottom plating, the impact loads applied to the tank bottom are as follows:

Longitudinal motion: $P_3 = 1.42\rho gkl\sin^2\delta$ kN/m^2

Transverse motion: $P_3 = 1.5\rho gb_f\sin^2\delta$ kN/m^2

where:

$$k = \begin{cases} 1 & L < 200 \\ 1.4 - 0.002L & L \ge 200 \end{cases};$$

δ — angle between the panel considered and the horizontal direction, in °.

(2) The impact loads in way of the lower part are evenly distributed within an area of $0.2b_f$ or $0.2l$ in height from the inner bottom plating and linearly reduced to 0 within the range extending 1 m upwards from such height.

2.8.6 For corners of longitudinal and transverse structures of tanks within the range of $0.15b_f$ or $0.15l$, the impact loads are determined by the following formula:

$$P_3 = \max\begin{cases} P_3(\text{longitudinal}) + 0.4P_3(\text{transverse}) \\ P_3(\text{transverse}) \end{cases}$$

2.9 Direct calculation of sloshing loads

2.9.1 This paragraph provides direct calculation method and program for sloshing loads, and with approval by CCS, other programs may be used to calculate sloshing loads.

2.9.2 Basic assumptions

The volume of fluid method is used for direct calculation of sloshing loads of cargo tanks, in association with the following assumptions:
(1) the fluid is non-compressible and viscous;
(2) free surface exists in fluid motion and no loss of fluid in tanks occurs during the motion;
(3) temperature change is not taken into consideration.

2.9.3 Basic principles

Coordinate systems are established for a two-dimensional space (x, y), as shown in Figure 2.9.3, where $O_oY_oZ_o$ is a permanent coordinate system fixed on earth, oyz is a coordinate system of motions fixed on cargo tank boundary; $(y_o(t), z_o(t))$, $\theta(t)$, $\dot{\theta}(t)$ and $(\ddot{y}_o(t), \ddot{z}_o(t))$ are respectively the position, angle, angular velocity and linear acceleration of the coordinate system of motions relative to the permanent coordinate system. Equations are developed based on basic principles of non-compressible fluid dynamics. The finite difference method is employed to discretize the equations.

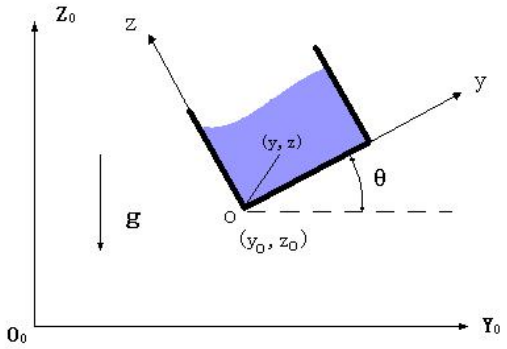

Figure 2.9.3 Two-dimensional coordinate system

2.9.4 Sloshing calculation program

CCS software for direct calculation of sloshing is employed for the calculation of sloshing loads and motion. The calculation model and distribution of grid cells are shown in Figure 2.9.4.

The size of grid cell is recommended to be 0.5 to 1 time the longitudinal spacing, and the ratio of side is to be approximate to 1 as far as possible for meshing. The hybrid factor is in general taken as 0.8.

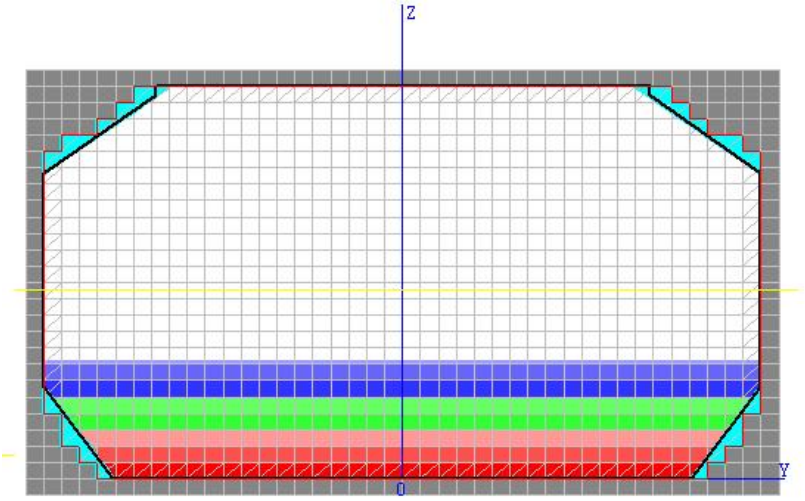

Figure 2.9.4 Grid cells in sloshing calculation

3 ASSESSMENT OF SCANTLING REQUIREMENTS FOR TANK STRUCTURE UNDER SLOSHING LOADS

3.1 General requirements

3.1.1 This Section specifies the scope of application and scantling requirements for sloshing loads applied to the hull structural members in cargo tank region.

3.1.2 The sloshing pressure used in this Section is the maximum value of sloshing loads calculated by the filling heights under consideration selected in accordance with 2.5 of this Appendix, where the level 3 sloshing load is to be based on the direct calculation of sloshing loads.

3.1.3 Assessment is to be carried out for the following structural members subjected to sloshing pressure due to longitudinal liquid motion:
(1) transverse tight bulkheads;
(2) inner deck;
(3) primary members;
(4) stiffeners on the transverse bulkheads and inner deck.
3.1.4 Assessment is to be carried out for the following structural members subjected to sloshing pressure due to transverse liquid motion:
(1) longitudinal tight bulkheads;
(2) hopper slope plating;
(3) inner hull slope plating;
(4) inner deck;
(5) primary members;
(6) stiffeners on the above structural members.

3.2 Assessment of tank structure under level 1 and level 2 sloshing loads

3.2.1 Plating forming tank boundaries

The thickness of plating forming tank boundaries, t, subjected to sloshing pressures is not to be less than that obtained from the following formula:

$$t = 0.0174\alpha_p s\sqrt{\frac{P}{C_a R_{eH}}} \quad \text{mm}$$

where: $\alpha_p = 1.2 - \frac{s}{2100 l_p}$, but to be taken not greater than 1.0;

s — stiffener spacing, in mm;

l_p — length of plate panel, to be taken as the spacing of primary members, unless carlings are fitted, in m;

P — sloshing load, to be taken as the greater of P_1 and P_2, in kN/m^2;

C_a — permissible plate bending stress coefficient, see Table 3.2.1;

R_{eH} — yield stress of the material, in N/mm^2.

Permissible bending stress coefficient, C_a, for assessment of sloshing on plates

Table 3.2.1

The permissible bending stress coefficient is to be taken as:

$$C_a = \beta_a - \alpha_a \frac{|\sigma_{hg}|}{R_{eH}} \text{ but not to be taken greater than } C_{a-\max}$$

where: β_a, α_a, $C_{a-\max}$ – permissible bending stress factors and are to be taken as follows:

Structural Member		β_a	α_a	$C_{a-\max}$
Longitudinal strength members in the cargo tank region including but not limited to: – inner deck; – inner hull plating; – longitudinal girders and stringers	Longitudinally stiffened plating	0.9	0.5	0.8
	Transversely or vertically stiffened plating	0.9	1.0	0.8
Other strength members including: – transverse bulkheads; – transverse stringers and web frames		0.8	0	0.8

σ_{hg} — hull girder bending stress calculated at the load calculation point and to be taken as:

$$\sigma_{hg} = \left(\frac{(z - z_{NA}) M_{sw}}{I_v}\right) \times 10^{-3} \quad \text{N/mm}^2$$

z — vertical coordinate of the load calculation point under consideration, in m;

z_{NA} — distance from the baseline to the horizontal neutral axis, in m;

M_{sw} — permissible hull girder hogging and sagging still water bending moment for seagoing operation, in kN.m, to be taken as the greatest absolute value;

I_v — vertical hull girder moment of inertia, at the longitudinal position being considered, in m^4;

R_{eH} — yield stress of the material, in N/mm^2.

3.2.2 Stiffeners on tank boundaries

The section modulus, W, of stiffeners on tank boundaries subjected to sloshing pressures is not to be less than that obtained from the following formula:

$$W = \frac{1.1 P s l_{bdg}^2}{f_{bdg} C_s R_{eH}} \qquad \text{cm}^3$$

where: l_{bdg} — effective bending span of stiffeners, in m;

C_s — permissible bending stress coefficient, see Table 3.2.2;

P — sloshing load, to be taken as the greater of P_1 and P_2, in kN/m^2;

s — stiffener spacing, in mm;

R_{eH} — minimum yield stress of the material, in N/mm^2;

f_{bdg} — bending moment factor to be taken as:

$f_{bdg} = 12$ for stiffeners fixed against rotation at each end. This is generally to be applied for scantlings of all continuous stiffeners;

$f_{bdg} = 8$ for stiffeners with one or both ends not fixed against rotation. This is generally to be applied to discontinuous stiffeners.

Permissible bending stress coefficient, C_s, for assessment of sloshing on stiffeners

Table 3.2.2

The permissible bending stress coefficient is to be taken as:

$C_s = \beta_s - \alpha_s \frac{|\sigma_{hg}|}{R_{eH}}$ but not to be taken greater than $C_{s-\max}$

where: β_s, α_s, $C_{s-\max}$ — permissible bending stress factors and are to be taken as follows:

Structural Member		β_s	α_s	$C_{s\text{-}max}$
Longitudinal strength members in the cargo tank region including but not limited to: – inner deck longitudinals; – stiffeners on inner hull plating	Longitudinal stiffeners	0.85	1.0	0.75
	Transverse or vertical stiffeners	0.7	0	0.7
Other strength members including: – stiffeners on transverse bulkheads		0.75	0	0.75

σ_{hg} — hull girder bending stress calculated at the load calculation point and to be taken as:

$$\sigma_{hg} = \left(\frac{(z - z_{NA}) M_{sw}}{I_v} \right) \times 10^{-3} \qquad \text{N/mm}^2$$

z — vertical coordinate of the load calculation point under consideration, in m;

z_{NA} — distance from the baseline to the horizontal neutral axis, in m;

M_{sw} — permissible hull girder hogging and sagging still water bending moment for seagoing operation, in kN.m, to be taken as the greatest absolute value;

I_v — vertical hull girder moment of inertia, at the longitudinal position being considered, in m^4;

R_{eH} — yield stress of the material, in N/mm^2.

3.3 Assessment of tank structural members under level 3 sloshing load

3.3.1 Plating forming tank boundaries

The thickness of plating forming tank boundaries, t, subjected to level 3 sloshing pressures is not to be less than that obtained from the following formula:

$$t = \frac{0.0174 \alpha_p s}{C_d} \sqrt{\frac{P}{C_a R_{eH}}} \quad \text{mm}$$

where: P — sloshing impact load P_3, in kN/m^2, to be calculated in accordance with 2.9;

C_d = 1.3, plate capacity correction coefficient;

other parameters are the same as those in 3.2.1.

3.3.2 Stiffeners on tank boundaries

The plastic section modulus, W_{pl}, of stiffeners on tank boundaries subjected to sloshing impact pressures is not to be less than that obtained from the following formula:

$$W_{pl} = \frac{1.1Psl_{bdg}^2}{f_{bdg}C_sR_{eH}} \qquad \text{cm}^3$$

where: P — sloshing impact load P_3, in kN/m^2, to be calculated in accordance with 2.9;

$C_s = 0.9$;

f_{bdg} — bending moment factor, to be taken as:

$$f_{bdg} = 8\left(1 + n_s / 2\right)$$

where: $n_s = 2.0$ for continuous stiffeners or where stiffeners are bracketed at both ends;

other parameters — the same as those in 3.2.2.

3.3.3 Where the ends of stiffeners are not arranged to be continuous through and alternative arrangements are used, the plastic section modulus, $W_{pl\text{-}alt}$, of stiffeners is not to be less than that obtained from the following formula:

$$W_{pl-alt} = \frac{16W_{pl}}{f_{bdg}} \qquad \text{cm}^3$$

where: f_{bdg} — bending moment factor, to be taken as:

$$f_{bdg} = 8\left(1 + n_s / 2\right)$$

where: $n_s = 0$ for both ends with low end fixity (simply supported);

$n_s = 1$ for one end equivalent to built-in and the other end simply supported.

3.3.4 The shear area, A_{shr}, of primary member web at any position along its span is not to be less than that obtained from the following formula:

$$A_{shr} = 10\frac{Q_{imp}}{C_t\tau_{yd}} \qquad \text{cm}^2$$

where: Q_{imp} — the greatest shear force due to impact for the position being considered, in kN, as determined in accordance with 3.3.5;

$C_t = 0.9$, permissible shear stress coefficient;

$\tau_{yd} = \frac{R_{eH}}{\sqrt{3}}$ N/mm^2;

R_{eH} — yield stress of the material, in N/mm^2.

3.3.5 For primary members, the shear force, Q_{imp}, is calculated by the following formula:

$$Q_{imp} = f_{pt}f_{dist}F_{imp}$$

where: f_{pt} — correction factor for the proportion of patch load acting on a single primary member, to be taken as:

$$f_{pt} = 0.5(f_{imp}^3 - 2f_{imp}^2 + 2)$$

f_{imp} — patch load modification factor, to be taken as:

$$f_{imp} = 0.5\frac{b_{imp}}{S}\text{, but not to be greater than 1.0}$$

f_{dist} — factor for the greatest shear force distribution along the span, see Figure 3.3.5;

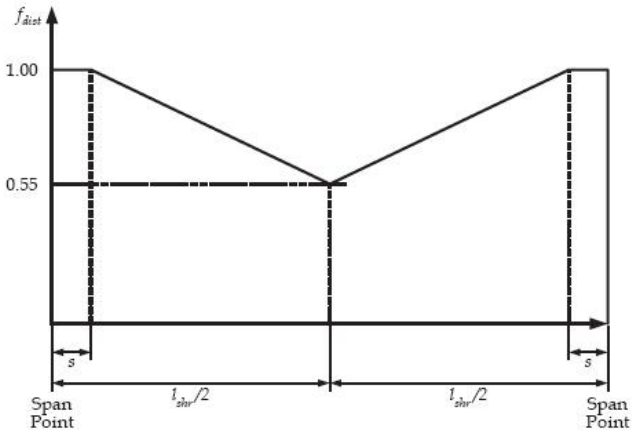

Figure 3.3.5 Distribution of f_{dist} along the Span

s — stiffener spacing, in m;

l_{shr} — effective shear span, in m;

$F_{imp} = P_3 l_{imp} b_{imp}$

where: P_3 — sloshing impact pressure, in kN/mm^2, as determined in accordance with 2.9;

l_{imp} — extent of impact load area along the span, in m, not to be greater than l_{shr} ;

b_{imp} — breadth of impact area supported by primary member, in m, not to be greater than S;

S — primary member spacing, in m.

4 DIRECT CALCULATION OF HULL STRUCTURAL STRENGTH UNDER SLOSHING LOADS

4.1 General requirements

4.1.1 This Section applies to the cargo tank FE analysis related to the hull structure of cargo tank under sloshing loads.

4.1.2 The assessment is to be carried out to primary members and transverse bulkheads in cargo tank region as well as support members of cargo containment system.

4.2 Structural FE model

4.2.1 The FE model of cargo tank used for the direct calculation and analysis of strength of cargo tank region is to comply with the requirements of Appendix 1 of this Chapter.

4.3 Loads

4.3.1 All load components with respect to the hull girder bending moment, liquid pressure inside and outside of tanks and other local pressures, inertia forces due to ship's motions are to be taken into account.

4.3.2 All load components with respect to the hull girder bending moment, liquid pressure inside and outside of tanks and other local pressures, inertia forces due to ship's motions are to be in accordance with the requirements of Section 2, Appendix 1 of this Chapter. The hull girder still water bending moment in sloshing condition is to be taken as 70% of maximum design still water bending moment value.

4.3.3 The sloshing pressure of liquid inside cargo tanks is to be in accordance with the requirements of 2.6~2.8, Section 2 of this Appendix.

4.4 Calculation conditions

4.4.1 The cargo tank FE analysis conditions under sloshing loads are given in Table 4.4.1.

4.4.2 The filling height under consideration in cargo tanks is to be determined in accordance with 2.5, Section 2 of this Appendix.

Sloshing load cases **Table 4.4.1**

Case	Load pattern	Draught	Coefficient of hull girder vertical wave bending moment k_{cV}	Coefficient of hull girder horizontal wave bending moment k_{cH}	External pressure		Wave heading angles and ship motions			
					k_c	k_{f0}	Wave angle	Heave	Pitch	Roll
LCA_L		2/3*d*	Sag 1.0	–	0.5	-1.0	0	Down	Bow down	–
LCA_T		2/3*d*	Sag 0.3	Tension port 0.3	0.5	-1.0	90	Down	–	Stbd up
LCB_L		2/3*d*	Hog 1.0	–	0.5	1.0	0	Up	Bow up	–
LCB_T		2/3*d*	Hog 0.3	Tension port 0.3	0.5	1.0	90	Up	–	Stbd up

4.5 Result evaluation

4.5.1 The assessment areas of FE analysis of cargo tank under sloshing loads are given in 4.1.1 and 4.1.2, Section 4, Appendix 1 of this Chapter.

4.5.2 The yield assessment criteria of structural members in sloshing condition are given in Table 4.5.2.

Yield strength assessment criteria **Table 4.5.2**

Structural member	Yield utilisation factor and permissible stress restriction
Hull girder longitudinal member plating and bulkhead plating	
Side shell, bilge plate, bottom shell, trunk deck slope plating and trunk deck plating, upper deck, cofferdam bulkheads, side watertight bulkheads, deck girders, double bottom girders, double side stringers, etc.	$\lambda_y \leq 1.0$, for bottom shell and double bottom girders $\lambda_y \leq 0.9$, for other structural members.
Inner deck plating and inner deck slope plating in direct contact with secondary barriers, side inner hull plating, inner bottom, inner hull slope plating, hopper slope plating	$\lambda_y \leq 0.90$
Primary supporting member plating	
Primary transverse supporting structures, e.g. side transverse web frames, trunk deck transverses, vertical diaphragms and horizontal stringers between cofferdam bulkheads, double bottom floors, and stiffening diaphragm plates and brackets between inner and outer hulls	$\lambda_y \leq 0.75$
Notes: (1) Yield utilisation factor $\lambda_y = \frac{\sigma_e}{R_{eH}}$ for plate element; $\lambda_y = \frac{\sigma_{rod}}{R_{eH}}$, for face plate of primary supporting members modelled by rod element or beam element. (2) For structural members subject to level 3 sloshing impact loads, the permissible stress may be taken as the yield strength R_{eH} of the material.	

4.5.3 Yield deformation is to be so controlled that maximum relative deformation of the plating between stiffeners of all hull panels (including inner bottom plating, hopper slope plating, inner hull plating, inner hull slope plating, inner deck plating and inner deck top plating as well as transverse bulkhead plating)/plating of unstiffened panels regarding periphery of insulations is generally not to be greater than 4.0 mm.

4.5.4 Refined model and assessment are to satisfy relevant requirements of 4.4, Section 4, Appendix 1 of this Chapter.

5 DIRECT CALCULATION OF STRUCTURAL STRENGTH OF PUMP TOWER UNDER SLOSHING LOADS

5.1 General requirements

5.1.1 This Section applies to the assessment of structural strength of pump tower under sloshing loads, taking into account the impact of temperature effect and inertial motion of hull.

5.1.2 The following primary structural members are to be included in the calculation model of pump tower structure:

(1) port/starboard discharge pipes;
(2) emergency pipe;
(3) filling pipe;
(4) brace;
(5) filling pipe and emergency pipe connecting bar;
(6) pump tower base;
(7) pumps.

The arrangement of primary structural members is as shown in Figure 5.1.2.

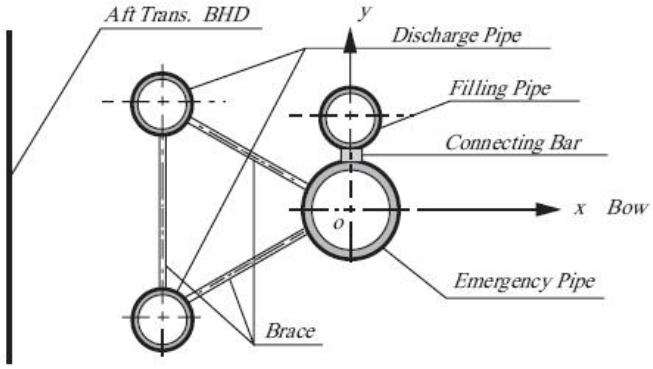

Figure 5.1.2 Arrangement of primary structural members of pump tower

5.1.3 Material properties

The pump tower is generally made of 300 series stainless steel. The physical properties of the common stainless steel 304L are given in Table 5.1.3 or reference is made to relevant provisions of Section 8, Chapter 3, PART ONE of Rules for Materials and Welding.

Properties of stainless steel 304L **Table 5.1.3**

No.	Item	Property
1	Yield strength	170 N/mm^2 at room temperature 200 N/mm^2 at -30℃ 277 N/mm^2 at -160℃
2	Tensile strength	485 N/mm^2 at room temperature
3	Elastic modulus	1.93×10^5 N/mm^2
4	Poisson ratio	0.3
5	Thermal expansion coefficient	16.8×10^{-6} /℃
6	Reference temperature	20℃

5.2 Selection of conditions and dominant load parameters

5.2.1 Calculation conditions

(1) Standard rule input conditions may be used directly as tank sloshing calculation conditions, including natural period of tank motion as well as maximum roll angle and pitch angle of hull motion, in which natural period of tank motion is calculated according to 2.4 of this Appendix, and maximum roll angle and

pitch angle are calculated according to 2.3.4(1), Appendix 1 of this Chapter.
(2) The second method is to calculate response amplitude operators (RAO) of dominant load parameters by means of seakeeping analysis based on equivalent design wave method and screen critical sloshing calculation condition. At the same time, wave encounter period and long-term extreme value of dominant load parameters are calculated for sloshing loads and structural analysis.
For method 2, according to relevant provisions of 2.3 of this Appendix, full load and ballast conditions are set as calculation condition for seakeeping analysis, and sloshing loads are calculated by the filling heights under consideration selected in accordance with 2.5 of this Appendix and applied to the FE model of pump tower. For full load conditions, filling levels of 50%*h* or more are to be selected. For ballast conditions, filling levels of less than 50%*h* are to be selected.

5.2.2 Dominant load parameters for sloshing motion

Seakeeping analysis is carried out in this Section, and dominant load parameters are determined as follows:
(1) Transverse motion

- roll motion, θ_1;
- transverse acceleration,

$$\xi''_2 + g\theta_1 - (Z_{CT} - Z_G)\theta''_1$$

(2) Longitudinal motion

- pitch motion, θ_2;
- longitudinal acceleration,

$$\xi''_1 - g\theta_2 + (Z_{CT} - Z_G)\theta''_2$$

where: Z_{CT}, in m, is the distance between the center of tank considered and the baseline; Z_G, in m, is the distance between the ship's center of gravity and the baseline.

5.3 Environmental conditions

5.3.1 Unless specially considered, the environmental condition of North Atlantic wave condition is generally required, and the North Atlantic wave data used are taken from the Wave Scatter Diagram of North Atlantic in IACS Rec. No34.

5.3.2 The two-parameter Bretschneider spectrum $S(\omega)$ is used and the wave spectrum function is given by:

$$S(\omega) = \frac{1.25\omega_p^4 H_s^2 e^{-1.25\left(\frac{\omega_p}{\omega}\right)^4}}{4\omega^5}$$

where: $S(\omega)$ — wave energy density, in m^2/s;
Ω — angular frequency, in rad/s;
ω_p — peak frequency, in rad/s, $\omega_p = 2\pi/T_p$, where T_p is defined in 2.4.1.

5.3.3 Specific sea condition

For LNG carriers intended to be partially loaded, sea conditions for the specific service area are generally to be analyzed by means of a wave scatter diagram for this area. A JONSWAP function $S(\omega)$ is used for the wave spectrum:

$$S(\omega) = \frac{\alpha g^2}{\omega^5}\exp\left[-\frac{5}{4}\left(\frac{\omega_p}{\omega}\right)^4\right] r^{\exp\left[-\frac{1}{\sigma^2}\left(\frac{\omega-\omega_p}{\omega_p}\right)^2\right]}$$

where: r — peak rise factor;
σ — peak shape factor;
α — dimensionless constant;
other parameters — as defined in 5.3.2.

5.4 Equivalent wave approach for sloshing motion

5.4.1 Analysis method

(1) The long-term extreme value prediction method is used to determine the maximum value of wave loads applied to the ship during its operation, generally corresponding to the maximum wave load encountered once in every 25 years. The long-term distribution of wave loads is calculated by combining the short-term predictions into the long term predictions based on the existing information on wave statistics, in which the extreme value of 10^{-8} probability level of exceedance is taken.

(2) A method of short-term extreme value prediction is used for the specific sea condition. At a given probability level, the sea condition corresponding to this level and having the highest wave height is to be obtained. The short-term extreme values are calculated based on this sea condition.

5.4.2 Determination of critical sloshing condition

With response amplitude operators (RAO) of dominant load parameters that are calculated from the sea-keeping analysis, the critical sloshing condition is defined on the frequency (ω) – heading (β) plane.

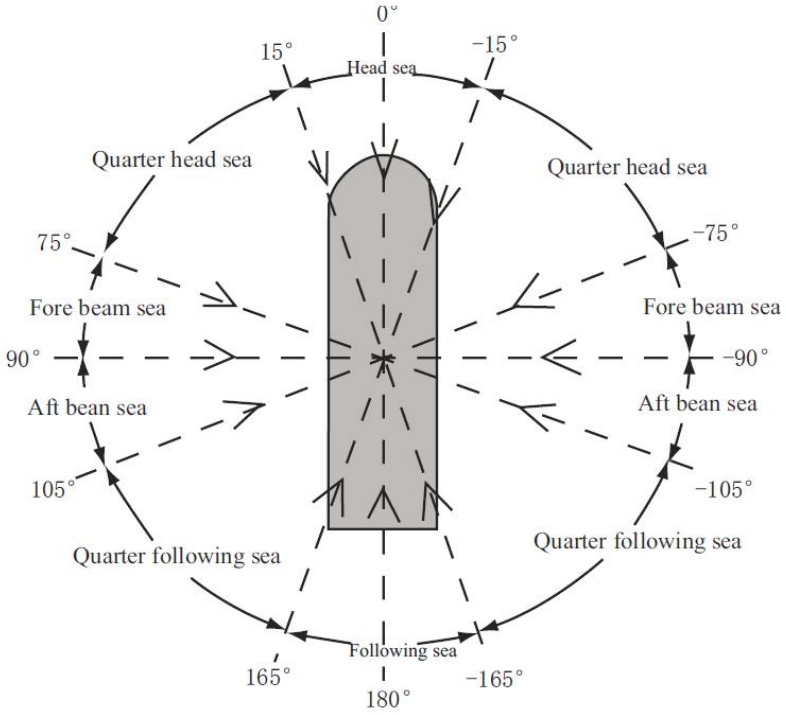

Figure 5.4.2 Distribution of wave heading angles around the girth of the ship

Figure 5.4.2 shows the distribution of wave heading angles around the girth of the ship. The following three principles are to be complied with in determining the critical sloshing condition:

- the response amplitude operator has the maximum value;
- the encounter period is in proximity to the sloshing motion period;
- the wave heading angle is within the range of maximum effects.

Based on the above principles, conditions for determining a critical sloshing condition are indicated in Table 5.4.2 below.

Conditions for determining a critical sloshing condition **Table 5.4.2**

No.	Motion	Formula for the conditions	Remarks
1	Transverse motion	$\lvert T_y - T_e \rvert < 0.3T_y$	where T_y and T_e are transverse sloshing motion period and wave encounter period respectively
		$RAO(\beta,\omega) > 0.7Max[RAO(\beta,\omega)]$	where the response amplitude operator is corresponding to the dominant load parameter
		$60^o \le \beta \le 90^o$	taking into account beam sea
2	Longitudinal motion	$\lvert T_x - T_e \rvert < 0.3T_x$	where T_x and T_e are longitudinal sloshing motion period and wave encounter period respectively
		$RAO(\beta,\omega) > 0.7Max[RAO(\beta,\omega)]$	where the response amplitude operator is corresponding to the dominant load parameter
		$0^o \le \beta \le 30^o$	taking into account head sea

5.5 Structural analysis of pump tower

5.5.1 Basic model

Global model or simplified model method can be used for pump tower structure analysis. Global model method is to have unified modeling by taking pump tower structure, pump tower liquid dome and base foundation as a global model, and simplified model method is to conduct simplified treatment to pump tower liquid dome and base foundation, or set the intersection of liquid dome and base foundations and pump tower structure as boundary condition. Models relating to pump tower liquid dome and base

foundation structure are to meet the requirements of Section 6 of this Appendix.

(1) Coordinate system

The coordinate system for pump tower finite element models is as shown in Figure 5.5.1（1）. It is a right-handed Cartesian coordinate system whose origin is located at the emergency pipe centerline. The *x*-axis is positive toward the bow, the *y*-axis is positive to port, and the *z*-axis is positive upward. A right-handed local Cartesian coordinate system is used for element whose origin is located at a node. The *x*-axis is along the element axis toward another node and the *y*-axis is normal to the element plane toward the outside.

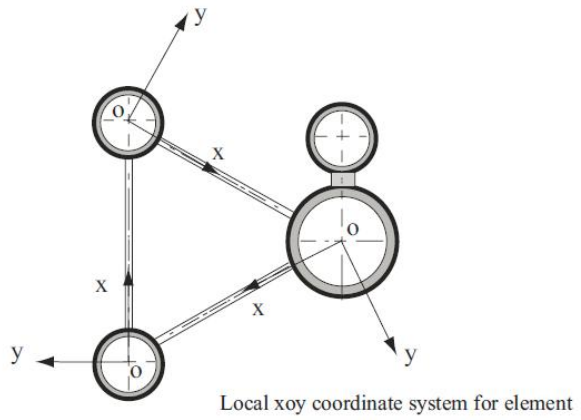

Figure 5.5.1(1) Local coordinate system for element

(2) Finite elements

The element types of pump tower components are to be in accordance with Table 5.5.1.

Finite element types **Table 5.5.1**

No	Structural component	Feature	Element type
1	Port/starboard discharge pipe, emergency pipe, filling pipe and brace	Circular piping structure	Beam element
2	Filling pipe and emergency pipe connecting bar	Rigid connection	Rigid rod element
3	Base foundation	Pump tower base foundation plate and connecting bracket	Plate element, beam element
4	Pumps	Cylindrical structure	Beam element

(3) Modeling principles

The following principles are applicable to the finite element modeling of the pump tower structure:

(a) for circular piping structures including port/starboard discharge pipes, emergency pipe, filling pipe and brace members, the FE nodes are the joint nodes;

(b) when simplified model method is used to evaluate the pump tower structure, the pump tower base structure is simulated by an “I” shape beam element. Face and web plates of the “I” shape beam are determined by the scantlings of pump tower base plates and connecting brackets. Plate or beam elements can also be used to simulate base plate and connecting bracket, and MPC (multi-point constraints) is used to connect circular pipe structure. MPC connecting method is the same as constraint condition of node 12 in Table 5.5.2.

(c) normally the pump tower is provided with two pumps. A cylindrical shell element having the same diameter, height and weight as those of the pump is employed as the equivalent, as shown in Figure 5.5.1(2).

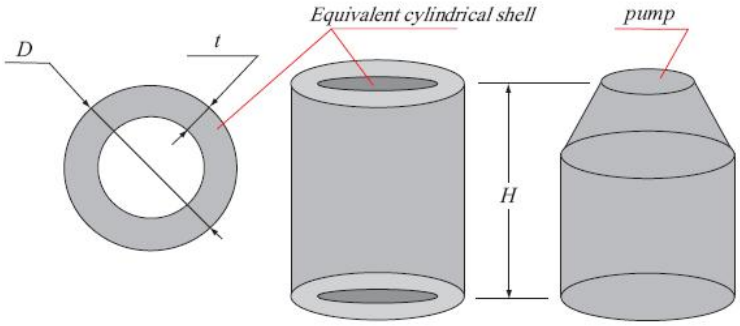

Figure 5.5.1(2) Pump and equivalent cylindrical shell

The thickness of the equivalent cylindrical shell may be calculated by the following formula:

$$t = \frac{D}{2} - \sqrt{\frac{\pi\rho HD^2 - 4W}{4\pi\rho H}}$$

where: t — thickness of the equivalent cylindrical shell, in mm;

D — pump diameter, in mm;

H— pump height, in mm;

W— pump weight, in kg;

ρ — pump material density, in kg/mm^3.

(d) When only the pump tower structure is evaluated, only boundary conditions in 5.5.2 of this Appendix may be considered for pump tower liquid dome structure. When pump tower liquid dome structure is evaluated, plate elements or beam elements are to be used to simulate inner hull deck and trunk deck. MPC (multi-point constraints) is to be used to connect main circular pipe structure of pump tower. MPC connecting method is the same as constraint condition of corresponding node in Table 5.5.2.

5.5.2 Boundary conditions

(1) Top

The boundary conditions of the nodes (i.e. 1, 2, 3, 4, 5, 6, 7 and 8) (as shown in Figure 5.5.2(1)) on the trunk deck and inner hull deck at top is given in Table 5.5.2.

(2) Bottom

The boundary conditions for displacement of node 12 at the base foundation of the pump tower FE model (as shown in Figure 5.5.2(1)) is given in Table 5.5.2.

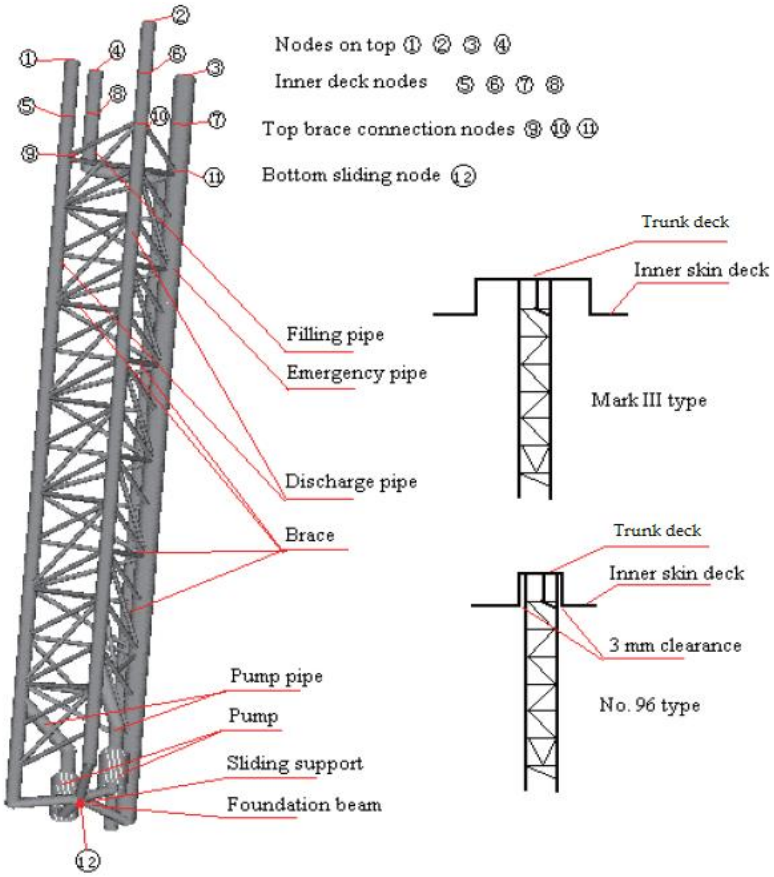

Figure 5.5.2(1) Pump tower structural model and nodes

Boundary conditions of pump tower displacement **Table 5.5.2**

No.	Displacement		Nodes for Mark III type			Nodes for No.96 type		
			1、2、3、4	5、6、7、8	12	1、2、3、4	5、6、7、8	12
1	X axis	Translation	Fixed	–	Fixed	Fixed	Fixed	Fixed
2		Rotation	–	–	Fixed	–	–	Fixed
3	Y axis	Translation	Fixed	–	Fixed	Fixed	Fixed	Fixed
4		Rotation	–	–	Fixed	–	–	Fixed
5	Z axis	Translation	Fixed	–	—	Fixed	–	–

6		Rotation	Fixed	–	Fixed	Fixed	–	Fixed

Note: "–" indicates the free motion of the nodes.

(3) Node constraint between elements

The normal connection between the FE model elements of pump tower may be simulated by the normal joint type of beam element nodes (i.e. constraint connection of six degrees of freedom). For the transverse connecting bar in way of the pump tower liquid dome structure as shown in Figure 5.5.2(2), the axial motion is free while radial motion is constrained. This end joint type may be specially dealt with by means of MPC (multi-point constraints) adopted at the ends of sliding joints as shown in Figure 5.5.2(3).

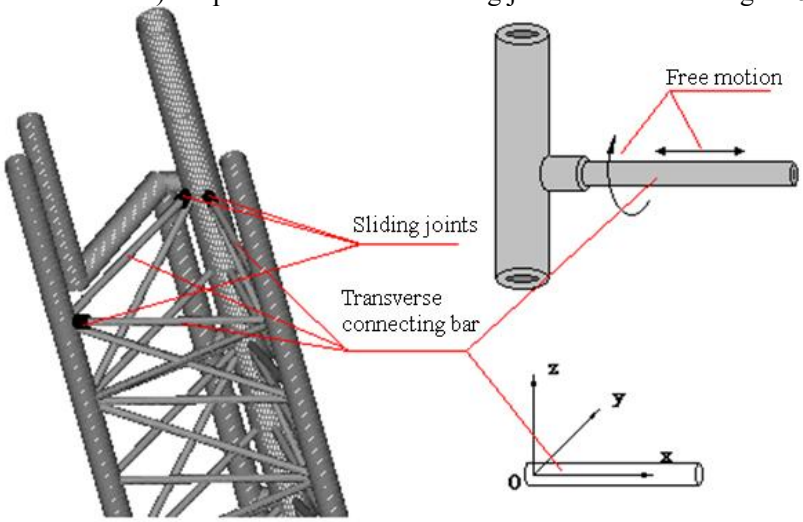

Figure 5.5.2(2) Transverse joints of pump tower liquid dome structure

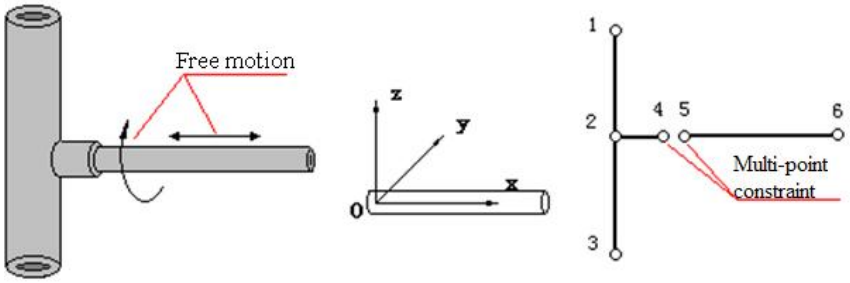

Figure 5.5.2(3) MPC adopted at the ends of sliding joints

5.5.3 Loads

(1) Sloshing loads

The liquid velocity and acceleration along the centerline of the pump tower can be obtained by means of the direct calculation of sloshing motion. The sloshing-induced load on the pump tower, i.e. Morison force $\vec{F}_M$, is calculated by the following formula:

$$\vec{F}_M = \frac{1}{2}\rho C_d \vec{U}(z)\left|\vec{U}(z)\right| D + \frac{\pi}{4}\rho C_m \vec{a}(z) D^2 \quad \text{N/m}$$

where: ρ — fluid density, in kg/m^3;

$U(z)$ — liquid velocity in the pump tower pipe centerline normal to the member, in m/s;

$a(z)$ — liquid acceleration in the pump tower pipe centerline normal to the member, in m/s^2;

D — diameter of transverse section of pump tower, in m;

C_m — inertia coefficient of Morison, normally taken as 2.0;

C_d — drag coefficient of Morison, taken as 1.2.

Morison force is exerted per unit length along the length of the structural member, and is also related with the liquid velocity and acceleration in the vertical direction. Hence the change of Morison force along the length and vertical direction of the member is to be taken into account in loading the FE model. The combined Morison force F_l acting on a structural member of the length of l is:

$$\vec{F}_l = \int_0^l \left[\frac{1}{2}\rho C_d \vec{U}(z)\left|\vec{U}(z)\right| D + \frac{\pi}{4}\rho C_m \vec{a}(z) D^2\right] dl \quad \text{N}$$

(2) Thermal loads

Thermal stresses induced by temperature changes are to be considered in the FE model. The calculation and

loading of the temperature field of pump tower are to be in accordance with the provisions of Appendix 3 of this Chapter.

(3) Inertial forces

Inertia accelerations due to ship motion and gravity are to be considered in the FE model. Inertia accelerations of pump tower in three directions can be obtained by calculation based on seakeeping analysis in this Section, or calculated according to 2.3.4(1), Appendix 1 of this Chapter.

5.6 Strength criteria

5.6.1 General requirements

(1) Stresses

In the Guidelines, the yield strength and buckling strength of the tubular elements and the punching shear strength in way of the joints are checked for various tubular structures. Primarily, the following four stresses on the tubular elements are considered:

(a) axial compressive stress σ_a;

(b) axial tensile stress σ_T;

(c) in-plane bending stress σ_I;

(d) out-of-plane bending stress σ_O.

(2) Basic parameters

Figure 5.6.1 shows the geometry of a typical tubular joint. The thick pipe is the chord while the thin one is the brace (including horizontal brace and sloping brace). Relevant parameters are given in Table 5.6.1.

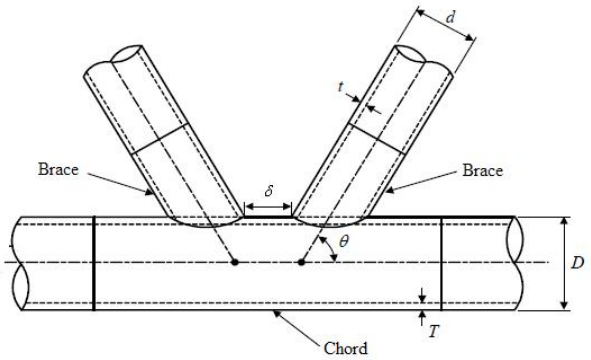

Figure 5.6.1 Typical tubular joint

Parameters **Table 5.6.1**

No.	Geometric parameter	Definition	Unit	Remark
1	l	Length without support	mm	
2	r	Radius of gyration	mm	
3	θ	Brace angle measured from chord	(°)	
4	t	Brace wall thickness	mm	
5	T	Chord wall thickness	mm	
6	δ	Clearance	mm	$\delta = 0$ for 1 brace; δ is taken as the clearance between the 2 braces furthest apart from each other for 3 or more braces when checking 2 braces furthest apart from each other
7	d	Brace diameter	mm	
8	D	Chord diameter	mm	
9	τ_a	Normal shear stress considered	N/mm^2	
10	τ_I	In-plane shear stress considered	N/mm^2	
11	τ_O	Out-of-plane shear stress considered	N/mm^2	
12	$[\sigma]_a$	Permissible axial compressive stress	N/mm^2	
13	$[\sigma]_T$	Permissible axial tensile stress	N/mm^2	
14	$[\sigma]_b$	Permissible bending stress	N/mm^2	
15	$[\tau]_a$	Permissible axial punching shear stress	N/mm^2	
16	$[\tau]_I$	Permissible in-plane punching shear stress	N/mm^2	
17	$[\tau]_o$	Permissible out-of-plane punching shear stress	N/mm^2	

No.	Geometric parameter	Definition	Unit	Remark
18	$[\sigma]_e$	Permissible Euler stress	N/mm^2	$[\sigma]_e = \dfrac{\pi^2 E}{\lambda_2^2}$
19	f_{ca}	Chord axial nominal stress	N/mm^2	σ_a or σ_T
20	f_{cI}	Chord in-plane bending stress	N/mm^2	σ_I
21	f_{cO}	Chord out-of-plane bending stress	N/mm^2	σ_O
22	f_{ba}	Brace axial nominal stress	N/mm^2	σ_a or σ_T
23	f_{bI}	Brace in-plane bending stress	N/mm^2	σ_I
24	f_{bO}	Brace out-of-plane bending stress	N/mm^2	σ_O
25	λ_1	Ratio of outer diameter to thickness of tubular elements		d/t or D/T
26	K	Effective length factor		1.0 for chord and 0.8 for brace
27	k_s	$k_s = R_{eH}/235$		
28	η	$\eta = t/T$		
29	μ	$\mu = d/D$		
30	γ	$\gamma = D/(2T)$		
31	λ_2	$\lambda_2 = Kl/r$		

Note: R_{eH} is the yield strength of the material, in N/mm^2.

5.6.2 Yield strength and buckling strength

(1) Permissible stress of tubular element

① The permissible axial compressive stress $[\sigma]_a$ is to be determined in accordance with the following formulae:

(a) For $\lambda_1 \le 60$:

$$[\sigma]_a = \begin{cases} \dfrac{k_s\left[1-0.5\left(\dfrac{\lambda_2}{C}\right)^2\right]\times 10^4}{70.922+15.957\dfrac{\lambda_2}{C}-5.319\left(\dfrac{\lambda_2}{C}\right)^3}, & \lambda_2 < C \\ \dfrac{5.147E}{\lambda_2^2}, & \lambda_2 \ge C \end{cases} \quad \text{N/mm}^2$$

where: $C = 0.29\sqrt{\dfrac{E}{k_s}}$

(b) For $\lambda_1 > 60$ and $\dfrac{k_s\lambda_1}{E}\left(642.34-90.08\lambda_1^{1/4}\right) \le 1$:

$$[\sigma]_a = \begin{cases} \dfrac{k_s\left(1-0.14024\lambda_1^{1/4}\right)\left[1-0.5\left(\dfrac{\lambda_2}{C}\right)^2\right]\times 10^4}{43.245+9.73\dfrac{\lambda_2}{C}-3.243\left(\dfrac{\lambda_2}{C}\right)^3}, & \lambda_2 < C \\ \dfrac{5.147E}{\lambda_2^2}, & \lambda_2 \ge C \end{cases}$$

where: $C = \sqrt{\dfrac{E}{k_s\left(19.53-2.739\lambda_1^{1/4}\right)}}$

(c) For $\lambda_1 > 60$ and $\dfrac{k_s\lambda_1}{E}\left(642.34-90.08\lambda_1^{1/4}\right) > 1$:

$$[\sigma]_a = \begin{cases} \dfrac{\dfrac{E}{\lambda_1}\left[1-0.5\left(\dfrac{\lambda_2}{C}\right)^2\right]\times 10}{27.78+6.25\dfrac{\lambda_2}{C}-2.083\left(\dfrac{\lambda_2}{C}\right)^3}, & \lambda_2 < C \\ \dfrac{5.147E}{\lambda_2^2}, & \lambda_2 \geq C \end{cases} \quad \text{N/mm}^2$$

where: $C = 3.236\sqrt{\lambda_1}$

② The permissible axial tensile stress is to be determined in accordance with the following formula:

$$[\sigma]_T = 141k_s \quad \text{N/mm}^2$$

③ The permissible axial bending stress is to be determined in accordance with the following formula:

$$[\sigma]_b = \begin{cases} 176.25k_s, & \lambda_1 \leq \dfrac{44}{k_s} \\ \left(197.4-\dfrac{408.9k_s\lambda_1}{E}\right)k_s, & \dfrac{44}{k_s} \leq \lambda_1 \leq \dfrac{88}{k_s} \\ \left(169.2-\dfrac{136.3k_s\lambda_1}{E}\right)k_s, & \dfrac{88}{k_s} \leq \lambda_1 \leq 300 \end{cases} \quad \text{N/mm}^2$$

(2) Strength criteria for tubular elements

① The strength criteria for axial compressive and bending is to comply with the following formulae:

(a) For $\dfrac{\sigma_a}{[\sigma]_a} > 0.15$:

$$\frac{\sigma_a}{[\sigma]_a} + \frac{([\sigma]_e - 0.4\sigma_a)}{([\sigma]_e - \sigma_a)} \cdot \frac{\sqrt{\sigma_I^2+\sigma_O^2}}{[\sigma]_b} \leq 1.0$$

$$\frac{\sigma_a}{0.6[\sigma]_a} + \frac{\sqrt{\sigma_I^2+\sigma_O^2}}{[\sigma]_b} \leq 1.0$$

(b) For $\dfrac{\sigma_a}{[\sigma]_a} \leq 0.15$:

$$\frac{\sigma_a}{[\sigma]_a} + \frac{\sqrt{\sigma_I^2+\sigma_O^2}}{[\sigma]_b} \leq 1.0$$

② The strength criteria for axial tensile and bending is to comply with the following formulae:

$$\frac{\sigma_T}{0.6[\sigma]_T} + \frac{\sqrt{\sigma_I^2+\sigma_O^2}}{[\sigma]_b} \leq 1.0$$

5.6.3 Punching shear strength

(1) Permissible punching shear stress of tubular joint

① Permissible axial punching shear stress:

$$[\tau]_a = 522C_Q \cdot \left(1.0 - \frac{\gamma\left(f_{ca}^2+f_{cI}^2+f_{cO}^2\right)}{1178133k_s^2}\right) \cdot \frac{k_s}{\gamma} \quad \text{N/mm}^2$$

② Permissible in-plane punching shear stress:

$$[\tau]_I = 522C_Q \cdot \left(1.0 - \frac{\gamma\left(f_{ca}^2+f_{cI}^2+f_{cO}^2\right)}{785422k_s^2}\right) \cdot \frac{k_s}{\gamma} \quad \text{N/mm}^2$$

③ Permissible out-of-plane punching shear stress:

$$[\tau]_O = 522C_Q \cdot \left(1.0 - \frac{\gamma\left(f_{ca}^2+f_{cI}^2+f_{cO}^2\right)}{1683047k_s^2}\right) \cdot \frac{k_s}{\gamma} \quad \text{N/mm}^2$$

The value of C_Q in the above formulae is taken in accordance with Table 5.6.3; however for the calculation of permissible axial punching shear stress, C_Q is to be taken not less than $(1.1+0.2/\mu)$. See Appendix 2A

of this Chapter for tubular joint types and categorization for pump tower.

Coefficient C_Q **Table 5.6.3**

<table>
<tr><td colspan="3">Tubular joint type</td><td colspan="2">K</td><td>T&Y</td></tr>
<tr><td colspan="3" rowspan="2">Axial tension/compression</td><td>$\gamma \le 20$</td><td>$\gamma > 20$</td><td rowspan="2">$(1.1+0.2/\mu)$</td></tr>

<tr><td>$\mu \le 0.6$</td><td colspan="3">$\left(1.37+\frac{0.67}{\mu}\right)$</td></tr>
</table>

(2) Punching stress considered of tubular joint

① Axial punching shear stress considered:

$$\tau_a = \eta f_{ba} \sin\theta \text{ , N/mm}^2$$

② In-plane punching shear stress considered:

$$\tau_I = \eta f_{bI} \sin\theta \text{ , N/mm}^2$$

③ Out-of-plane punching shear stress considered:

$$\tau_O = \eta f_{bO} \sin\theta \text{ , N/mm}^2$$

(3) Punching shear strength criteria

The punching shear strength of tubular joint is to comply with the following formulae:

$$\left(\frac{\tau_I}{[\tau]_I}\right)^2 + \left(\frac{\tau_O}{[\tau]_O}\right)^2 \le 1.0$$

$$\left|\frac{\tau_a}{[\tau]_a}\right| + \frac{2}{\pi}\arcsin\left(\sqrt{\left(\frac{\tau_I}{[\tau]_I}\right)^2 + \left(\frac{\tau_O}{[\tau]_O}\right)^2}\right) \le 1.0$$

6 DIRECT CALCULATION OF STRUCTURAL STRENGTH OF PUMP TOWER LIQUID DOME AND BASE FOUNDATION

6.1 General requirements

6.1.1 This Section applies to the assessment of direct calculation of structural strength of pump tower liquid dome and base foundation.

6.1.2 Structural analysis of pump tower liquid dome mainly aims at pump tower piping structure stretching into inner deck, including discharge pipe, filling pipe and emergency pipe. Pump tower base foundation analysis mainly aims at pump tower base foundation plate and supporting structure.

6.1.3 Global model method can be used to conduct modeling and analysis by taking the pump tower structure as well as pump tower liquid dome and base foundation as a global model, and independent modeling analysis can also be carried out to pump tower liquid dome and base foundation.

6.2 Structure modeling

6.2.1 For the coordinate system, element type and modeling principles of global model, see relevant requirements of Section 5 of this Appendix.

6.2.2 Pump tower base foundation model is at least to include structure model of pump tower base plate and pump tower supporting structures, as shown in Figure 6.2.2(1). Pump tower liquid dome structure model is to take pump tower center as origin, extending to girders or longitudinal bulkheads along ship breadth direction and extending to transverses or transverse bulkheads along ship length direction, as shown in Figure 6.2.2(2).

6.2.3 The mesh size of plate elements in the model is to be of reasonable distribution. For positions with complicated structure, the mesh size is not to be greater than 50 mm × 50 mm, and good transition is to be kept as a whole.

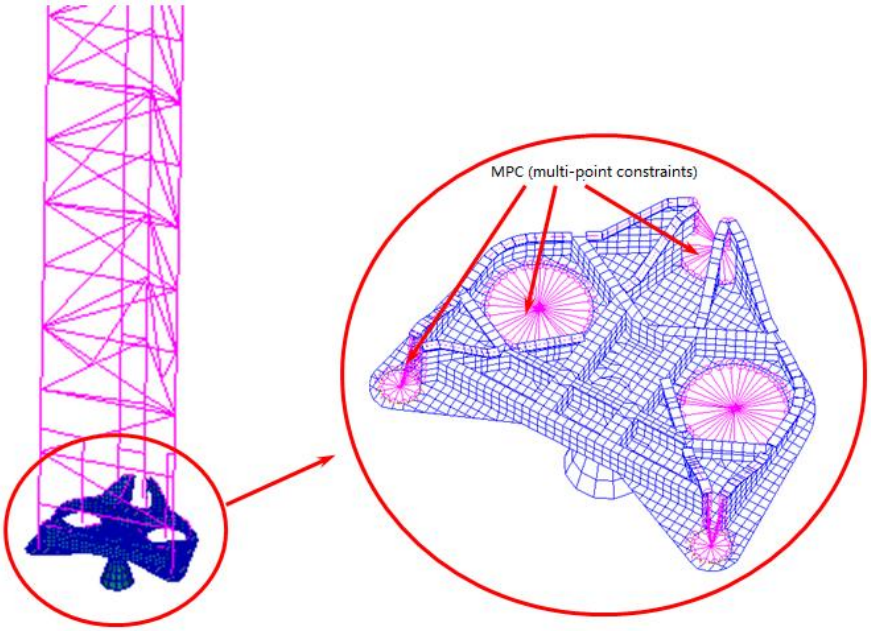

Figure 6.2.2(1) Pump tower base structure FE model

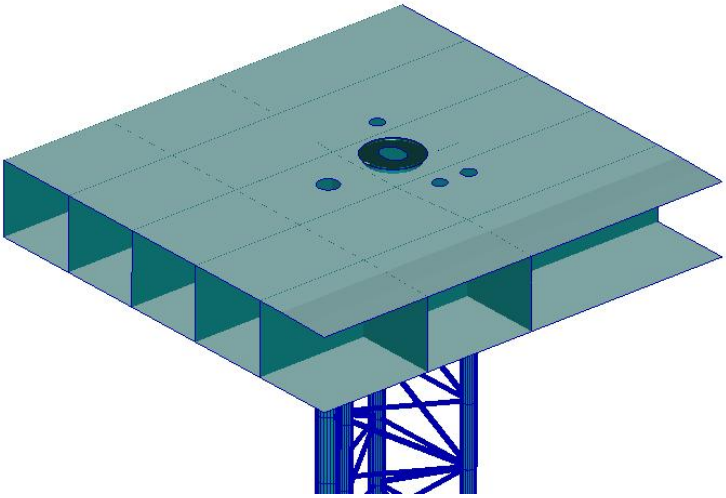

Figure 6.2.2(2) Pump tower liquid dome structure FE model

6.3 Boundary conditions

6.3.1 When the global model method is used, the connecting points of pump tower liquid dome model extending to corresponding web frame position are set as free support or fixed support. For the boundary conditions of connecting points of pump tower base and supporting structure as well as connecting points of base plate and circular pipe structure, see 5.5.2 of this Appendix.

6.3.2 When independent modeling analysis is carried out to pump tower liquid dome and base foundation, boundary conditions are to be set according to direct calculation result of the pump tower structure carried out according to Section 5 of this Appendix.

6.4 Loads

6.4.1 For loads applied to pump tower, see 5.5.3, Section 5 of this Appendix.

6.4.2 When the global model method is used, sloshing loads are to be applied to pump tower piping system, and temperature load and inertia acceleration are to be applied uniformly to the global model.

6.4.3 When independent modeling analysis is carried out to pump tower liquid dome, direct calculation of structural strength of pump tower is to be carried out according to the requirements of Section 5 of this Appendix, and node displacement, force and bending moment at the connection of top are to be extracted from calculation result as input data to be applied to corresponding nodes of liquid dome structure model.

6.4.4 When independent modeling analysis is carried out to base foundation, direct calculation of structural strength of pump tower is to be carried out according to the requirements of Section 5 of this

Appendix, and reaction force at bottom is to be extracted from calculation result as input data to be applied to corresponding position of model by converting area of contact plate at base foundation to equivalent and evenly distributed pressure.

6.5 Stress criteria

6.5.1 When yield strength of plate element and beam element of pump tower liquid dome and base foundation structure is evaluated, permissible stress is shown in Table 6.5.1.

Permissible stress **Table 6.5.1**

Structure	Element type	Equivalent stress (Von Mises stress)
Pump tower liquid dome and base foundation structure	Plate element and beam element	$0.85R_{eH}$

Note: 1 R_{eH} — yield stress of the material, in N/mm^2, and for stainless steel, 0.2% test stress is adopted. When applicable, effect of temperature on yield stress of the material is to be considered.

2 Plate element stress is to use membrane stress, i.e. mid-surface stress of plate element.

6.5.2 When the equivalent stress of elements within refined area exceeds permissible value, mean stress with area equivalent to standard mesh size and obtained from fine mesh analysis is not to exceed permissible value provided in Table 6.5.1.

7 STRUCTURAL VIBRATION EVALUATION OF PUMP TOWER

7.1 General requirements

7.1.1 This Section provides the methods and requirements for structural vibration evaluation of pump tower.

7.1.2 The type of pump tower structure is to comply with the requirements of 5.1.2, Section 5 of this Appendix.

7.2 Structure modeling

7.2.1 Pump tower structure model used for analyzing vibration characteristics is to comply with the requirements of 5.5.1, Section 5 of this Appendix.

7.2.2 Unit mass of liquid in piping system of pump tower is to be considered according to the following formula:

$m = \rho\pi\dfrac{D^2}{4}$ for the mass of liquid inside piping system:

$m = \rho C_m\pi\dfrac{D^2}{4}$ for the mass of attached liquid outside piping system:

where: ρ — fluid density, in kg/m^3;

D — diameter of piping system, in m;

C_m — coefficient, to be taken as 1.

7.3 Loading height

7.3.1 Both light ship condition and loading condition are to be considered in the pump tower structural vibration analysis.

7.3.2 For light ship condition, the loading height is equal to 0, and the inherent frequency is the upper limit value of pump tower structure.

7.3.3 The loading height under loading condition is to be in accordance with the requirements of 2.5, Section 2 of this Appendix, in which inherent frequency at 95% loading height is treated as the lower limit value of pump tower structure, and the inherent frequency at other loading heights is not to be lower than the above-mentioned limit value.

7.4 Excitation frequency

7.4.1 In addition to steam turbine propulsion type, vibration excitation frequency of main engine is to be considered.

7.4.2 Excitation frequency of propeller is to be based on revolution speed of propeller. The upper limit value is to be taken as the revolution speed of main engine at the maximum output power and the lower limit value is to be taken as 75% of revolution speed of main engine at the maximum output power.

7.5 Restrictions for avoiding resonance

7.5.1 There is to be ±20% of difference between inherent frequency of pump tower at each loading height and excitation frequency.

7.5.2 Where sufficient frequency reserve cannot be guaranteed, vibration response analysis is to be carried out to the pump tower structure in the cargo tank adjacent to the engine room of whole ship FE model. The peak value of pump tower vibration response is not to be greater than 15 mm/s.

Appendix 2A TUBULAR JOINT TYPES AND CATEGORIZATION

1 GENERAL PROVISIONS

1.1 This Appendix applies to the tubular joint types and categorization for pump tower.

1.2 For those tubular joint types for pump tower not covered in this Appendix, the categorization and strength check are to be approved by CCS.

2 TUBULAR JOINT TYPES

2.1 Typical tubular joint types

The typical tubular joint types for pump tower are as shown in Table 2.1.

Typical tubular joint types for pump tower Table 2.1

No.	Typical joint	Description
1		(1) Emergency pipe and brace intersections; (2) Tubular joints classified as K, T & Y types; (3) Check of compressive bending strength, tensile bending strength and punching shear strength
2		
3		
4		(1) Discharge pipe and brace intersections; (2) Tubular joints classified as K, T & Y types; (3) Check of compressive bending strength, tensile bending strength and punching shear strength
5		
6		
7		(1) Brace intersections; (2) Check of compressive bending strength and tensile bending strength
8		

2.2 In calculation, the relationship between the chord and braces (e.g. the geometries and relative locations) is to be determined according to the joint structure at first. The joint is then to be classified in accordance with the magnitude and direction of loads applied on the joint ends.

3 TUBULAR JOINT CATEGORIZATION

3.1 Tubular joint categorization

A tubular joint is formed by each chord/brace intersection, classified as K, T and Y types. In a plane considered, one or more tubular joints are formed by the chord connected to one or more braces. The tubular joint needs to be classified according to the magnitude and type of axial loads applied to the braces, where K type represents the equilibrium of the axial loads of each brace and T or Y type represents the equilibrium the axial loads of brace and the shear on chord.

3.2 The specific standards for categorization are as follows:

(1) For tubular joint with only one brace on one side, it is treated as T or Y type as the axial load of brace is only balanced by the shear on chord.

(2) For tubular joint with only two braces on one side, it is treated as T or Y type where the axial load of either brace is zero (as shown in Figure 3.2(1)).

(3) For braces carrying axial loads in direct equilibrium, all tubular joints are treated as K type (as shown in Figures 3.2(2),(3),(4)).

(4) For braces carrying part of their loads in equilibrium, the proportion of each joint needs to be obtained by interpolation according to the magnitude of loads and the permissible stress is calculated by means of weighted average (as shown in Figures 3.2(5),(6)).

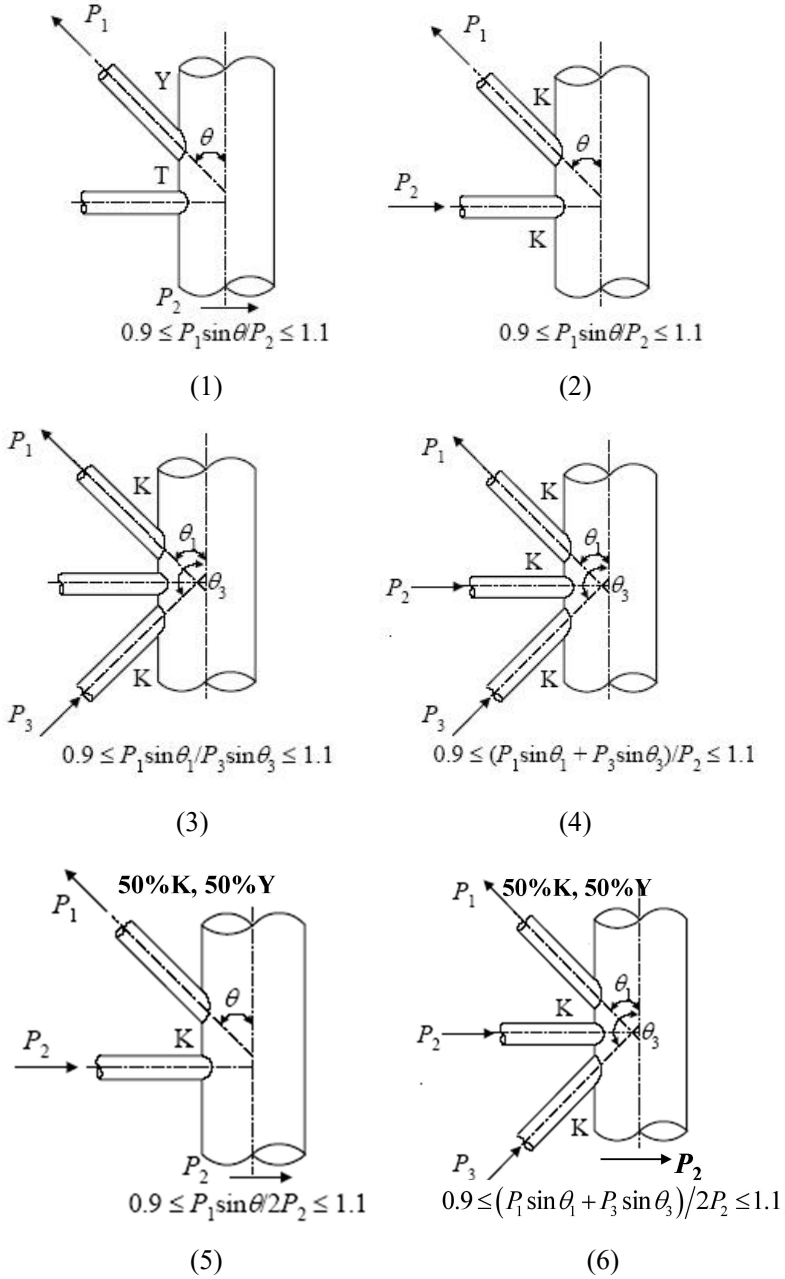

Figure 3.2 Definitions of typical tubular joint types in pump tower

APPENDIX 3 CALCULATION OF TEMPERATURE FIELD AND THERMAL STRESS

1 GENERAL PROVISIONS

1.1 General requirements

1.1.1 This Section specifies the provisions for the analysis of temperature field of three dimensional space and analysis method of thermal stress related to the cargo tank region and pump tower of membrane tank liquefied gas carriers. Where other calculation methods are used, they are to be agreed by CCS.

1.1.2 In the calculation of temperature field and thermal stress, recognized finite element thermal and structural analysis programs are to be used.

1.2 Definitions

1.2.1 The symbols of this Appendix are defined as follows (unless otherwise specified):

k_e — equivalent heat conduction coefficient, in W/(mK);

h — convective heat exchange coefficient, in W/(m^{2}K);

T — temperature, in ℃;

T_c — design temperature of liquid cargo, in ℃, to be taken as -163℃ for LNG;

α — linear expansion coefficient, in 1/K;

σ_e — equivalent calculation stress of structural element, in N/mm^2, as defined in Appendix 1 of this Chapter;

R_{eH} — yield strength of material in different temperature conditions, in N/mm^2, see Table 5.1.3, Appendix 2 of this Chapter. The intermediate value is to be obtained from linear interpolation.

2 STRUCTURAL MODEL

2.1 Model for temperature field analysis

2.1.1 The FE model for temperature field calculation is to cover the hull structure, primary and secondary insulations within the scope of the object to be analyzed (e.g. every cargo tank in the bow, amidships and stern area).

2.1.2 The analysis model is to cover the forward, aft cofferdams and cargo tanks. Where the structure and boundary condition are symmetrical from port to starboard, the 1/2 calculation model may be taken. Where the structure and boundary condition are symmetrical from port to starboard and from fore to aft, the 1/4 calculation model may be taken. A typical 1/4 FE analysis model for temperature field analysis is as shown in Figure 2.1.2.

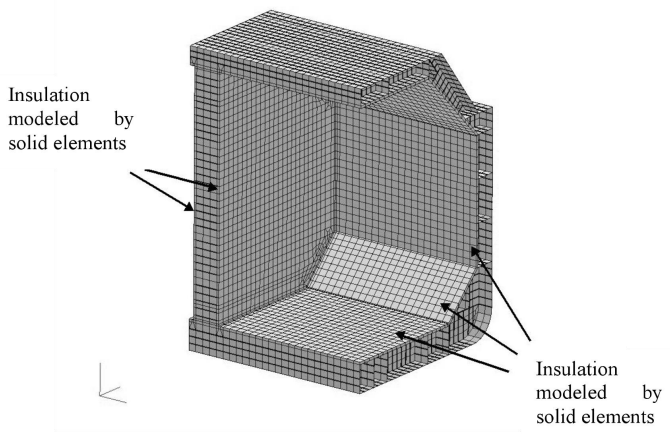

Figure 2.1.2 FE Model for temperature field calculation

2.1.3 The element types and meshing size of the FE model of hull structure are to comply with the requirements of 3.2, Appendix 1 of this Chapter.

2.1.4 The primary and secondary insulations of cargo tanks are to be modeled by solid elements, generally hexahedral elements.
2.1.5 Where the solid elements are used to model multiple layers of insulation formed by different materials, the equivalent heat conduction coefficient is to be used as the heat conduction coefficient of elements. For insulation formed by N layers of materials, its equivalent heat conduction coefficient is to be calculated in accordance with the following formula:

$$k_e = \frac{\sum_{i=1}^{N} \delta_i}{\sum_{i=1}^{N} \frac{\delta_i}{k_i}}$$

where: δ_i — thickness of the i^{th} layer of material, in m;

k_i — heat conduction coefficient of the i^{th} layer of material, in W/(mK).

2.2 Model for pump tower
2.2.1 Refer to 5.5.1, Appendix 2 of this Chapter for the requirements for the model of thermal stress calculation of pump tower and the value of material factor is taken according to 5.1.3, Appendix 2 of this Chapter.

3 CALCULATION OF TEMPERATURE FIELD OF HULL

3.1 General requirements
3.1.1 The calculation results of temperature field of this Section may be used as reference for determination of hull steel grades, analysis of structural thermal stress and calculation of daily boil off rate of cargo containment systems.
3.1.2 In this Section, the distribution of temperature field of structures is to be obtained through thermal analysis with the given ambient temperature and cargo temperature.
3.1.3 The calculation of this Appendix is based on:
(1) a steady state heat transferring in three-dimensional space, no change of material parameters and boundary conditions is made in conjunction with any temperature change in the analysis of linear heat conduction;
(2) only the effects of changes in the temperature field on the machinery field are considered without taking account of the effects of the latter on the former.
(3) the heat is transferred within the hull structure and between hull structural members by conduction, and that heat exchange between air, sea water and hull structural members is convection only.

3.2 Mode of heat transfer
3.2.1 For the calculation of hull temperature field, the following modes of heat transfer are assumed:
(1) convective heat transfer between plates of hull structure and air within tanks;
(2) convective heat transfer between plates of hull structure and external air, taking into account forced convective heat exchange for any wind speed;
(3) convective heat transfer between plates of hull structure and sea water;
(4) radiation heat transfer between plates of hull structure and external environment;
(5) radiation heat transfer between shell plating and inner hull plating (when the temperature field is used for calculation of nominal daily Boil Off Rate).

3.3 Calculation conditions
3.3.1 For different calculation purposes, the external conditions for calculation of hull temperature field are as follows:
(1) for the calculation of temperature distribution of hull structure and determination of steel grades where the primary insulation completely fails and the low-temperature cargo directly acts on the inner surface of secondary insulation;
(2) for the assessment of the efficiency of cargo containment systems of membrane tank liquefied gas carriers and calculation of nominal daily Boil Off Rate (detailed calculation methods are given in Appendix 3B of this Chapter) where equator condition is considered (see Table 3.3.2), primary and secondary insulations are complete and low-temperature cargo directly acts on the inner surface of primary insulation;
(3) other calculation purposes deemed necessary by CCS or the owner.

3.3.2 The external ambient temperature conditions are at least to include IGC condition, USCG condition and equator ambient condition, see Table 3.3.2.

External ambient conditions **Table 3.3.2**

	IGC	USCG	USCG (sea areas in Alaska)	Equator
Air temperature (℃)	5	-18	-29	45
Sea water temperature (℃)	0	0	-2	32
Wind speed (kn)	0	5	5	0
Liquid cargo (℃)	T_C			

3.4 Boundary conditions

3.4.1 The boundary condition of convective heat exchange is used between plates of hull structure and air, and between plates of hull structure and sea water. The convective heat exchange coefficient is to be selected as appropriate. Where specific values are unavailable, it may be determined by using recognized empirical formulae of thermodynamics.

3.4.2 In calculation of convective heat exchange coefficient between plates of hull structure and air, the effect of hull framing on the attached shell plating needs to be considered. In general the hull framing is considered as cooling rib.

3.4.3 For the inner surface of insulation in direct contact with cargo, the boundary condition of temperature or convective heat exchange may be defined.

3.4.4 The air temperature of enclosed tanks is to be taken as appropriate, or obtained by iterative direct calculations by referring to the recommended method in Appendix 3A of this Chapter.

3.4.5 For any heat source within the hull (e.g. the heating system provided in cofferdams), the heat source is to be applied to the hull as an appropriate boundary condition.

3.5 Selection of steel grades

3.5.1 The hull temperature field with the minimum draught in loaded condition is to be used as the loading condition for determination of steel grades of structures.

3.5.2 The scope of application of steel grades in different environmental conditions is given in Table 3.5.2.

Scope of application of steel grades **Table 3.5.2**

	IGC	USCG	USCG (Alaskan waters)	Equator
Scope of application of steel grades	Whole cargo tank area	Inner hull and connected members of cargo tank area	Inner hull and connected members of cargo tank area	Not applicable

3.5.3 The steel grades of hull materials are to be selected in accordance with Table 6.5 of Chapter 6 of PART THREE of CCS Rules for Construction and Equipment of Ships Carrying Liquefied Gas in Bulk.

3.5.4 For environmental conditions of USCG and USCG (Alaskan waters), the steel grade of deck stringer plate and sheer strake is not to be lower than grade E, and the bilge strake is to be grade D or E.

4 CALCULATION OF TEMPERATURE FIELD AND THERMAL STRESS OF PUMP TOWER STRUCTURE

4.1 Calculation conditions

4.1.1 See relevant provisions of 2.5, Appendix 2 of this Chapter for determination of cargo filling height within tanks.

4.1.2 The calculation of thermal stress of pump tower may include thermal load case and load combination.

4.1.3 In thermal load case, only the effect of steady state thermal load on the pump tower structure in different loading conditions is considered.

4.1.4 The strength calculation of pump tower in load combination is to include the following loads for calculation:

(1) steady state thermal load in different loading conditions;

(2) sloshing load in corresponding loading condition, see provisions of 5.5.3(1), Appendix 2 of this Chapter;

(3) inertial force, see provisions of 5.5.3(3), Appendix 2 of this Chapter;
(4) weight of structural members.

4.2 Boundary conditions

4.2.1 See relevant provisions of 5.5.2, Appendix 2 of this Chapter for the constraint types of pump tower nodes.

4.2.2 During the analysis of temperature field of pump tower, the temperature difference between the tank top and bottom is to be considered, and as a result, the temperature distribution within the tank is generally assumed as follows: T_c is defined as below the free surface of cargo and T_{top} is the temperature of tank top. Where no specific value is available, it may be assumed that T_{top}= -30℃, and the temperature is linearly distributed from -163℃ at the free surface to -30℃ at the tank top. The distribution of temperature along the centerline of pump tower is as shown in Figure 4.2.2.

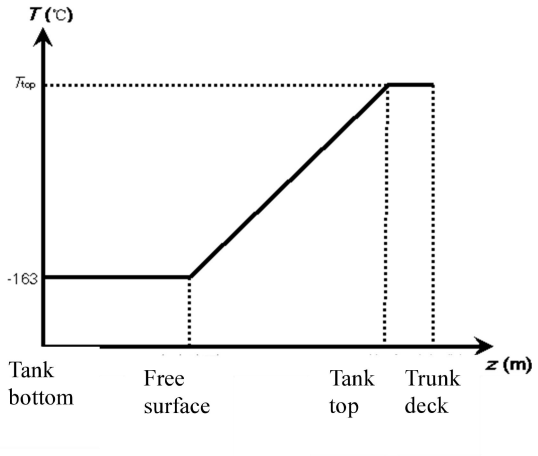

Figure 4.2.2 Assumed distribution of temperature along the centerline of pump tower

4.3 Criteria for thermal stress calculation

4.3.1 Where only the thermal load case is considered, the criteria for checking the thermal stress of pump tower structure is as follows:

$\eta \leq 0.1$

where: η — utilization factor, $\eta = \sigma_e / R_{eH}$.

4.3.2 For local area of thermal stress concentration, e.g. the connection of braces to piping and the top of pump tower, special consideration may be given to its strength criteria.

4.3.3 The criteria for the calculation of strength of pump tower in load combination is to be in accordance with 5.6, Appendix 2 of this Chapter.

Appendix 3A ITERATIVE CALCULATION METHOD IN RELATION TO THE TEMPERATURE OF AIR WITHIN TANKS OF HULL

1 General provisions

1.1.1 This Appendix provides an efficient calculation method recommended for the temperature of air within tanks of hull, which is based on the analysis of FE value.

2 Iterative calculation process

1.2.1 The air temperature within a tank is calculated in accordance with the following formula:

$$T_c = \frac{\sum h_i A_i T_{si}}{\sum h_i A_i}$$

where: T_c — air temperature of tank, in℃;

h_i — convection coefficient, in W/(m^{2}K);

A_i — area of the i^{th} plate in contact with air within the tank (during the calculation, the added surface area due to hull framing need not be considered);

T_{si} — temperature of the i^{th} plate in contact with air within the tank, in ℃, which can be taken as mean temperature of some nodes in the middle of plate.

1.2.2 The iterative calculation process of air temperature within tanks of hull is as shown in Figure 1.2.2.

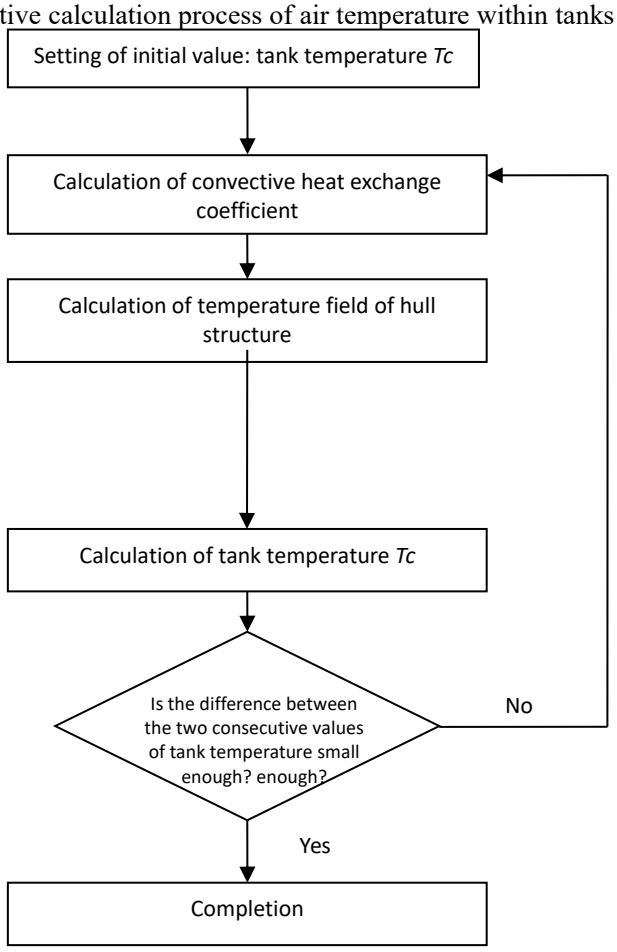

Figure 1.2.2 Calculation process of air temperature within tanks

Appendix 3B CALCULATION OF NOMINAL DAILY BOIL OFF RATE

1 General provisions

1.1.1 The nominal daily boil off rate (BOR) of LNG within cargo tanks is to be calculated and checked based on the calculation results of temperature field of hull.

2 Calculation conditions

2.1.1 During the calculation of nominal daily boil off rate, refer to the requirements of 3.2.1 of Appendix 3 for the mode of heat transfer for the calculation of hull temperature field, taking due consideration of various modes of heat transfer, e.g. those requirements in 3.2.1(4) and (5) of Appendix 3.

2.1.2 Refer to the requirements of 3.3.1(2) of Appendix 3 for calculation conditions.

3 Calculation methods

3.1.1 The nominal daily BOR is calculated in accordance with the following formula:

$$BOR = \frac{86400Q}{\gamma \rho V} \times 100\%$$

where: Q — total heat flow of heat exchange between LNG within the cargo tank of LNG carrier in steady state and the external environment, in W;

γ — boil off potential of LNG, in J/Kg; where specific value is not available, it may be taken as 5.1×10^5 J/Kg;

ρ — density of LNG, in Kg/m^3;

V— actual maximum loading capacity of cargo tank, in m^3.

3.1.2 The heat flow Q may be obtained by the following calculation method:

(1) For a surface of solid element in contact with LNG, read the heat flow density of its associated nodes to calculate the average value q_i, which is multiplied by the area A_i of the solid element, i.e. $Q_i = q_i A_i$, where Q_i is the heat flow on the element, as shown in Figure 3.1.2.

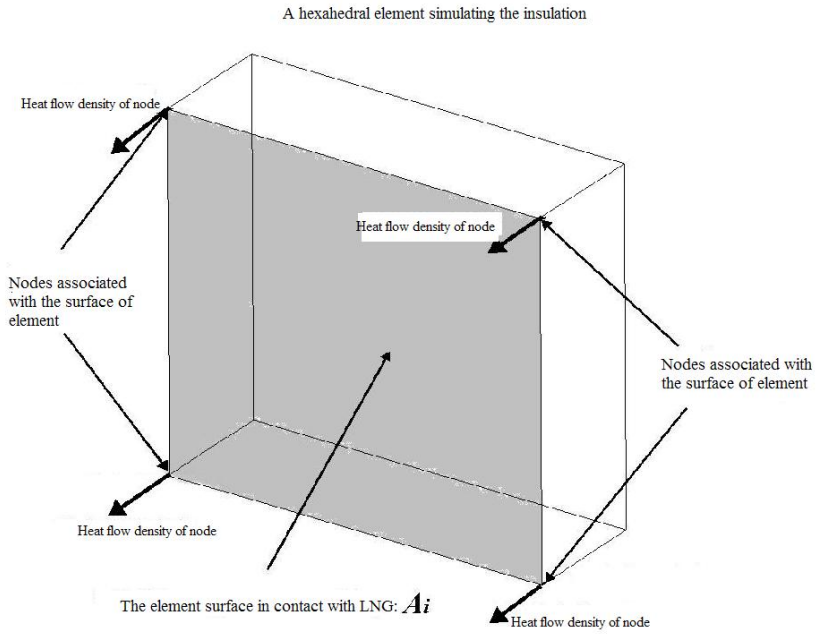

Figure 3.1.2 Calculation of heat flow

(2) Q_i of all the surfaces of solid element in contact with LNG are summed up so that $Q = \sum_i Q_i$.

4 Criteria for calculation results

4.1.1 In general, the reasonable range of nominal daily BOR in various thermal load cases is between 0.10% and 0.15%. For large membrane tank liquefied gas carrier, its BOR value is close to the lower limit

and for small membrane tank liquefied gas carrier, the value is close to the upper limit.

4.1.2 The limit value of maximum daily BOR is to be provided and guaranteed by the designer of cargo containment systems.

APPENDIX 4 DIRECT CALCULATION OF GLOBAL STRENGTH OF SHIPS

1 GENERAL PROVISIONS

1.1 General requirements

1.1.1 The global ship analysis in this Appendix is based on dynamic loading approach, wave load for global ship analysis is obtained by hydrodynamic direct calculation under design loading condition so as to truly reflect various extreme conditions that the ship encountered during navigation at sea. Structural analysis is based on whole ship FE model.

1.2 Flow chart of direct calculation of global strength of ships

1.2.1 The flow chart of direct calculation of global strength of ships is shown in Figure 1.2.1, mainly including the following process:

(1) actual loading condition is selected from the loading manual and static load is determined by the selected loading conditions;

(2) for each selected loading condition, relevant hydrodynamic analysis is carried out to obtain transfer function of each dominant load parameter (see 3.3.2);

(3) long-term prediction is carried out according to sea condition information to obtain ultimate value of dominant load parameter;

(4) equivalent design wave is determined according to the ultimate value of dominant load parameter;

(5) hydrodynamic analysis is carried out according to design wave to obtain wave load;

(6) static load is combined with dynamic load to obtain load value used for FE analysis;

(7) whole ship FE modelling is carried out and model mass property is adjusted so as to reflect full-scale ship mass distribution;

(8) modelling of refined model is carried out by means of insertion or sub-model;

(9) structural analysis and result examination are carried out, including global and local deformation, reaction force, etc.;

(10) yield strength evaluation is carried out;

(11) buckling strength evaluation is carried out;

(12) re-analysis is carried out according to design modification (if necessary).

Of the above, items (1) to (6) are for load calculation, see for details 3 and 4 of this Appendix; items (7) to (12) are for structural analysis, see for details 2 and 5 of this Appendix.

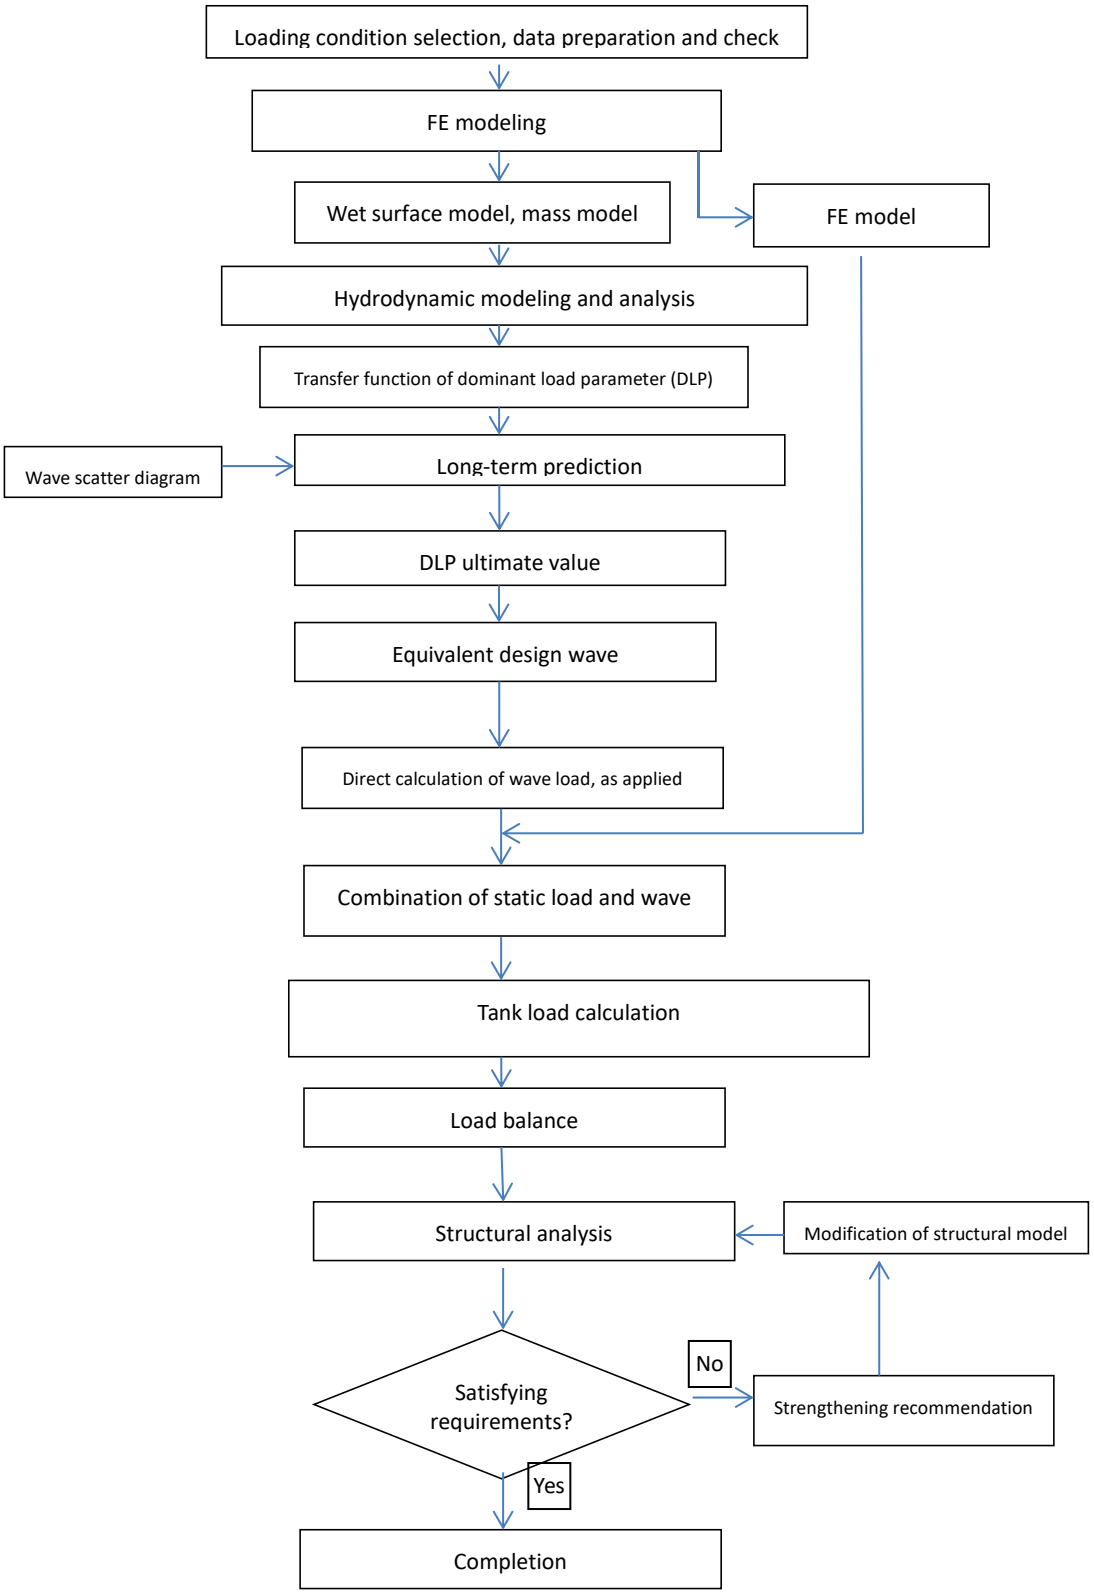

Figure 1.2.1 Flow chart of global ship analysis

2 FINITE ELEMENT MODEL

2.1 Whole ship model

2.1.1 Whole ship model is to include all main hull structure, trunk deck and deckhouse structure.

2.1.2 Inner side and outer shell plating, cofferdam transverse bulkheads, deck transverses and girders, side transverses and stringers, bottom floors and girders are to be simulated by plate elements, FE mesh is to be divided according to the spacing of longitudinals/stiffeners. Longitudinals, stiffeners and face plates of primary supporting members are to be simulated by beam elements, taking eccentric effect into consideration. Webs of primary members are to be divided into at least three elements in vertical direction.

2.1.3 The size of FE model is to be based on as-built scantlings of hull structures.

2.1.4 In order to apply inertial force accurately, FE model is to be able to reflect actual mass features of hull structures and equipment, including amount of mass, mass centroid and mass distribution. Equipment or liquids in small tanks may be simulated by mass concentration elements, but these mass elements are to be effectively connected with hull structures and the rigidity of hull structures is not to be changed.

2.2 Local fine mesh model

2.2.1 For critical areas of high stress, local fine mesh analysis is to be carried out. Sub-model or insertion method may be applied for local structural analysis.

2.2.2 Critical areas are to be selected according to the global strength analysis results so as to carry out local fine mesh analysis. Critical areas are to include the following locations (see Figures 2.2.2(1) and 2.2.2(2)):

(1) in way of upper and lower knuckle joints of hopper slope plating in way of transverse web frame, and in way of the connection of lower knuckle joints of inner hull slope plating to side stringers;

(2) at the intersection of double bottom girder and deck girder and transverse bulkhead;

(3) at the intersection of side stringer and transverse bulkhead;

(4) transitional bracket toes at fore and aft ends of trunk deck;

(5) openings on longitudinal bulkhead around the connection of deckhouse and trunk deck;

(6) transitional area at the end of inner hull longitudinal bulkhead in No.1 tank;

(7) trunk deck gas dome openings and longitudinal coaming toes (if any).

For the above-mentioned areas, if stress of coarse mesh exceeds 85% allowable stress, refining analysis is to be carried out. For other areas, if stress of coarse mesh exceeds 95% allowable stress, refining analysis is to be carried out.

2.2.3 The size of fine mesh is not to be more than 50 mm × 50 mm, and for detailed requirements of refined mesh, see 4.4, Appendix 1 of this Chapter.

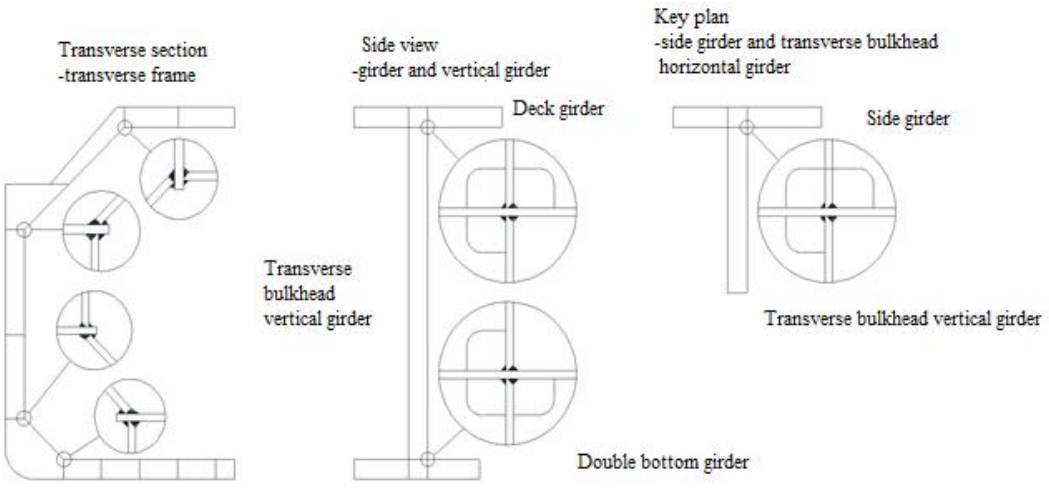

Figure 2.2.2(1) Refined area of cargo tank structure

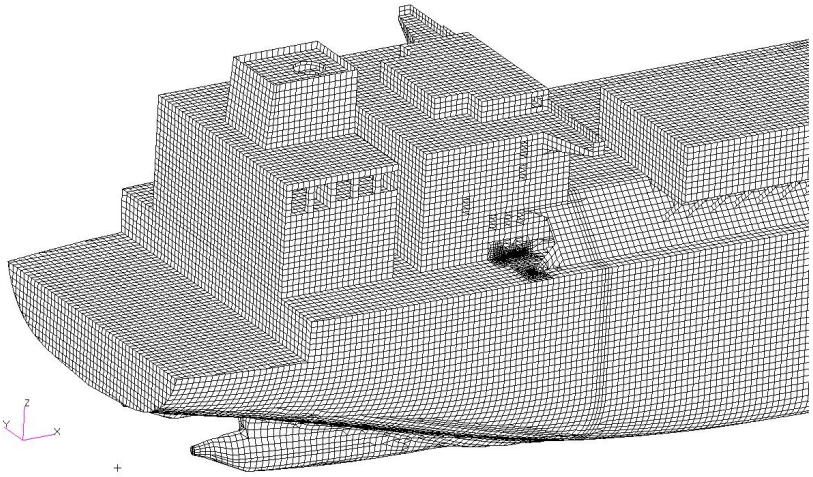

Figure 2.2.2(2) Aft end of trunk deck and deckhouse opening

3 CALCULATION CONDITION

3.1 Calculation conditions

3.1.1 Calculation conditions are composed of loading condition and wave condition.

3.2 Loading condition

3.2.1 Loading condition is to be selected from the loading manual, which is generally to include:
(1) full load (maximum design liquid cargo density); (F)
(2) normal ballast; (B)
(3) one tank void (if any); (V1,V2…)
(4) two adjacent tanks void (if any). (V12,V23…)
(5) sing tank load (if any) (V234, V124…)
At the same time, other worse loading conditions in the loading manual are also to be taken into account.
where: V1 means that the first tank is void and so on for other symbols.

3.3 Wave condition

3.3.1 Ships will be affected by various wave loads (sea water dynamic pressure, inertia force, tank pressure, etc.) during navigation at sea, such loads constitute a dynamic spatial force system. Load parameters are used to describe certain characteristics of these loads as an integrity, e.g. bending moment at amidship, shearing force in way of 1/4*L*, acceleration at bow, heeling angle, etc.
3.3.2 When a certain load parameter reaches the ultimate value, the ship will be affected by ultimate wave load, and this may be the dangerous condition. Specific load parameter is to be selected according to various ship types to determine wave condition considered. The load parameter reaching ultimate value is to be treated as dominant load parameter.
3.3.3 Wave load is induced by equivalent design wave which is determined according to dominant load parameter. Therefore, dominant load parameter reaches ultimate value due to equivalent design wave, and meanwhile, all other wave loads acting on hull may also be determined.
3.3.4 In global ship analysis for membrane tank liquefied gas carrier, the following wave dominant load parameters are to be taken into account respectively for wave conditions:
(1) vertical wave bending moment (hogging and sagging); (BM)
(2) vertical wave shearing force (+/-), considering two positions in way of 0.25*L* and 0.75*L* along the ship's length; (SFA, SFF)
(3) vertical acceleration at bow (upward/downward), the considered point is taken as the top of intersection between forward bulkhead of No.1 cargo tank and the longitudinal central line; (VA)
(4) transverse acceleration at bow (port/starboard), and the point considered is taken as the same

as (3). (TA)

3.4 Condition combination

3.4.1 Calculation conditions are composed of loading condition and wave condition, which are determined according to 3.2 and 3.3 of this Appendix respectively, and the calculation condition combination is shown in Table 3.4.1.

Calculation condition **Table 3.4.1**

Dominant load parameter / Loading condition	Bending moment at amidship	Shearing force in way of 1/4*L*	Shearing force in way of 3/4*L*	Vertical acceleration at bow	Transverse acceleration at bow
Full load	F_BM	F_SFA	F_SFF	F_VA	F_TA
Ballast	B_BM	B_SFA	B_SFF	B_VA	B_TA
One tank void	V1_BM V2_BM …	V1_SFA V2_SFA …	V1_SFF V2_SFF …	V1_VA V2_VA …	V1_TA V2_TA …
Two adjacent tanks void	V12_BM V23_BM …	V12_SFA V23_SFA …	V12_SFF V23_SFF …	V12_VA V23_VA …	V12_TA V23_TA …
Single tank load	V234_BM V134_BM …	V234_SFA V134_SFA …	V234_SFF V134_SFF …	V234_VA V134_VA …	V234_TA V134_TA …

Note: Definitions of symbols in various conditions are shown in 3.2.1 and 3.3.4.

4 CALCULATION LOAD AND BOUNDARY CONDITIONS

4.1 Load component

4.1.1 Load is to be divided into static load and dynamic load.

4.1.2 Static load is determined by the selected loading conditions, including gravity of hull and stores, external hydrostatic pressure and tank static pressure.

4.1.3 Dynamic load is obtained by direct calculation according to equivalent design wave, including inertia force of hull and stores, sea water dynamic pressure and tank dynamic pressure.

4.2 Hydrodynamic analysis and transfer function

4.2.1 Three-dimensional potential flow procedure is to be used for hydrodynamic analysis so as to calculate hull response on wave. In calculation, the viscous damping of rolling motion is to be taken into account, of which the value may be obtained by test or semi-empirical formula. In the case of absence of relevant information, 5%~10% critical damping may be taken.

4.2.2 Each mass model for hydrodynamic analysis is to reflect full-scale mass characteristics under the corresponding loading conditions, and hydrodynamic mesh is to reflect actual hull configuration and floating condition (draught, trim and heel).

4.2.3 In order to apply gravity and inertia force on the FE model accurately, mass property of FE model is to be adjusted so as to reflect mass distribution of full-scale ship. The full-scale FE model as adjusted is to be used as mass model in hydrodynamic analysis. At the initial stage of design, a simplified model which can simulate mass property of full-scale ship accurately may also be used.

4.2.4 In hydrodynamic analysis, transfer function of dominant load parameter mentioned in 3.3.4 is to be calculated so as to carry out long-term prediction analysis to determine the ultimate value of dominant load parameter. Where hydrodynamic analysis is carried out, transfer function at wave heading angle and frequency which the hull may be affected is to be calculated. The input wave parameters are:

(1) wave frequency: 0.2~1.5 rad/s for extent, 0.05 rad/s for step length;

(2) wave heading angle: 0º ~180º for extent, 15º for step length.

4.2.5 If hydrodynamic analysis is carried out by time domain method, time history is to be converted to transfer function by proper means, i.e. time history after reaching stable condition is to be selected for conversion.

4.2.6 The maximum value of frequency-wave heading angle combination is to be selected from transfer function of each dominant load parameter to determine the design wave. In general, the

maximum transfer function of vertical bending moment and vertical shearing force occurs under the heading wave condition, and the maximum heeling angle, maximum vertical acceleration and maximum transverse acceleration will occur under beam sea or oblique sea condition.

4.3 Sea condition information and load prediction

4.3.1 In the unrestricted service, scatter diagram and wave spectrum given by IACS REC.34 are to be used for sea condition information.

4.3.2 The ultimate value of dominant load parameter is to be obtained by long-term prediction according to transfer function. When a long-term prediction of dominant load parameter is carried out, exceedance probability of 10^{-8} is generally to be taken.

4.3.3 When a long-term prediction is carried out, short-crested wave is to be used, and square of cosine is to be taken for energy spreading function.

4.3.4 Considering operational experience at ultimate sea conditions, when the prediction of horizontal and vertical accelerations and heeling angle is carried out, exceedance probability of $10^{-6.5}$ may be taken.

4.4 Equivalent design wave

4.4.1 Each wave condition has its corresponding equivalent design wave. The equivalent design wave determined in 4.2.6 makes dominant load parameter reach its ultimate value and meanwhile determines other wave loads under such condition. Equivalent design wave may be defined by wave heading angle, wave length, phase and wave amplitude.

4.4.2 The combination which makes transfer function of dominant load parameter reach the maximum value is to be taken for wave heading angle and wave length of equivalent design wave, and the phase which makes transfer function reach the ultimate value is to be taken for the phase of equivalent design wave.

4.4.3 Under full load condition, the design wave amplitude of vertical wave hogging bending moment determined by direct calculation may be adjusted based on the wave hogging bending moment in 2.2.3.1, Chapter 2 of this PART so as to make its bending moment value equivalent. The design wave amplitude obtained by this method may be treated as the hogging design wave amplitude under other loading conditions and the sagging design wave amplitude under various loading conditions.

4.4.4 Except for those mentioned in 4.4.3, the design wave amplitude is to be obtained by dividing ultimate value of dominant load parameter by maximum value of transfer function.

4.4.5 Each wave load (sea water dynamic pressure, inertia force, etc.) used for structural analysis is to be determined according to design wave. Either non-linear method or combination of linear hydrodynamic procedure and wave surface correction may be used for direct calculation of wave load.

4.4.6 For wave dynamic load and inertia force, the corresponding load value obtained by above-mentioned methods are to be directly applied on FE model. Wave dynamic pressure is to be applied on shell in the form of positive normal pressure, and inertial force is to be applied on FE model by means of acceleration field and mass distribution.

4.5 Internal pressure of tank

4.5.1 In calculation of internal pressure of tank, the effects of steam pressure, gravity, motion and acceleration are to be taken into account. Where linear hydrodynamic analysis is used, the horizontal component of gravity due to ship's attitude (roll angle, pitch angle) is not taken into account for acceleration. Therefore the effects of acceleration component are to be included in the tank pressure calculation.

4.5.2 In calculation of tank pressure, an acceleration vector is first to be calculated according to acceleration and ship's attitude (roll angle, pitch angle), to obtain positions of reference points for tank pressure calculation. Then, the pressure on any point may be obtained according to the vector and reference point. Schematic plan is shown in Figure 4.5.2. In actual calculation, the combination of vectors in three directions is to be considered.

4.5.3 Acceleration is to be obtained in way of the center of tank considered according to the result of hydrodynamic calculation. For the bulkhead with tanks at both sides, loading is carried out according to the tank conditions respectively.

4.5.4 Considering static load and wave load, the combined tank pressure is to be calculated by

the following formula:

$$p = p_0 + \rho h\left[\left(g + a_v\right)^2 + \left(g_T + a_T\right)^2 + \left(g_L + a_L\right)^2\right]^{1/2} \times 10^{-3} \quad \text{MPa}$$

where: p_0 —steam pressure, in MPa;

ρ —liquid density, in t/m^3;

h —distance from pressure calculation point to reference point for tank pressure calculation, in m;

a_v — vertical acceleration at the center of tank considered, in m/s^2;

a_T — transverse acceleration at the center of tank considered, in m/s^2;

a_L — longitudinal acceleration at the center of tank considered, in m/s^2;

g_T — transverse component of gravity acceleration due to ship roll in ship coordinate system, in m/s^2;

g_L — longitudinal component of acceleration of gravity due to ship pitch in ship coordinate system, in m/s^2.

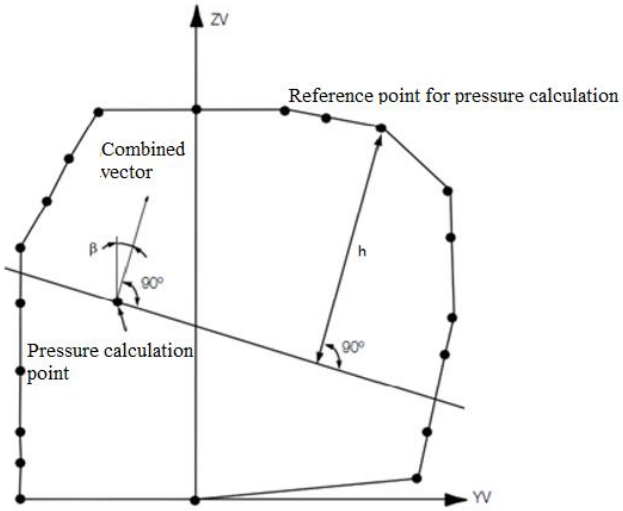

Figure 4.5.2 Tank pressure calculation method

4.6 Load equilibrium adjustment

4.6.1 By the action of above-mentioned loads, the whole ship FE model is to be in a dynamic balance state of total force system.

4.6.2 Prior to structural calculation, unbalanced force and moment on each direction of model are to be calculated, and equilibrium adjustment is to be carried out by proper means, e.g. the above-mentioned unbalanced force and moment may be removed by means of adjustment of floating condition.

4.7 Boundary conditions

4.7.1 As the model is in an equilibrium state, only the boundary conditions restraining rigid body motion of six degrees of freedom need to be set for structural analysis, as shown in Figure 4.7.1:

(1) Node 1 at the aft end: restraining the displacement in transverse direction;

(2) Node 2 at the fore end: restraining the displacement in three directions;

(3) Nodes 3 and 4 at port and starboard sides of stern transom plate: restraining the displacement in vertical direction.

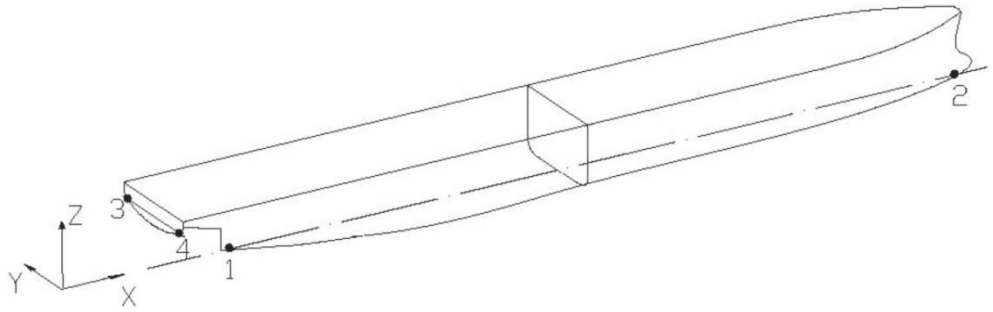

Figure 4.7.1 Diagram of boundary conditions

5 STRENGTH EVALUATION

5.1 Evaluation areas

5.1.1 Evaluation areas are to cover the whole cargo tank area and the transition structures of main longitudinal members in the engine room area and bow area. The following structural members in the evaluation areas are to be verified in accordance with the criteria in 5.2 and 5.3:
(1) main structural members (longitudinal, transverse) in the cargo tank area;
(2) forward transverse bulkheads of the engine room area and main supporting members, as well as the transition structures of trunk deck and inner deck in the engine room area;
(3) collision bulkheads and main supporting members, as well as the transition structures of trunk deck and inner deck in the bow area.

5.2 Yield strength

5.2.1 Yield strength criteria are as follows:

$$\sigma \le [\sigma]$$

where: σ —work stress, i.e. Von Mises equivalent stress of plate element center corresponding to longitudinal spacing mesh area, or axial stress of beam element, in N/mm^2;
$[\sigma]$—allowable stress, in N/mm^2, to be calculated by the following formula:

$$[\sigma] = \lambda_y \times \frac{223}{K} \quad \text{for coarse mesh;} \quad [\sigma] = \lambda_y \times \frac{357}{K} \quad \text{for refined area}$$

where: K—material factor;
λ_y —see Table 5.1.1.

Table 5.1.1

Structural members	λ_y
Bottom plating, inner bottom plating, transverse bulkhead plating	0.8
Deck plating, side shell and inner hull plating, hopper slope plating, bilge plating, watertight bracket and girder	0.9
Plating of all non-watertight members, face plate of primary members	1
Other structural members except for those mentioned above	1

5.3 Buckling strength

5.3.1 The buckling strength is to be checked with reference to the provisions for buckling strength check of hull structure in Appendix 1 of this Chapter.

Section 2 ADDITIONAL REQUIREMENTS FOR MACHINERY INSTALLATIONS 3-380

CHAPTER 1 GENERAL

Section 1 REQUIREMENTS FOR CLASSIFICATION

1.1.1 Conditions of classification for machinery installations

1.1.1.1 Main propulsion and auxiliary machinery installations together with their associated equipment, boilers, pressure vessels, pumping and piping systems, and gearing fitted in ships are to comply with the relevant requirements prescribed in this PART.

1.1.1.2 For the requirements for machinery installations of small ships and ships in restricted service, reference is made to the provisions in Chapter 16 of this PART and Chapter 3 of PART TEN.

1.1.1.3 In addition, the machinery installations are to comply with the applicable requirements of PART ONE of the Rules.

1.1.2 Class notations

1.1.2.1 For the specific class notations of ships, reference is made to the relevant provisions in Chapter 2, PART ONE of the Rules.

1.1.3 Plans and documents

1.1.3.1 Prior to the commencement of ship construction, plans and documents as listed in the respective Chapters of this PART are to be submitted for approval. Other plans and documents may be required to be submitted as deemed necessary for individual cases.

1.1.3.2 Any major alterations to basic design, materials or other aspects of the approved plans are to be re-submitted to CCS for approval.

1.1.3.3 For products approved by CCS, the submission of such plans and detailed information are not necessary.

1.1.4 Product survey

1.1.4.1 For the certification requirements and product survey of machinery installations, reference is made to the relevant provisions in Chapter 3, PART ONE of the Rules.

Section 2 GENERAL PROVISIONS

1.2.1 Ambient conditions

1.2.1.1 The main and auxiliary engines, shafting and machinery equipment essential to classification are to be so designed, type-selected and arranged as to ensure compliance with the provisions of 1.2.1.2 and 1.2.1.3.

1.2.1.2 Considering the type, size and service conditions of the ship, smaller angles of inclination may be permitted. See Table 1.2.1.2 for specific requirements.

Angle of inclination of ships **Table 1.2.1.2**

Installations and equipment	Angle of inclination① (°)			
	Athwartships		Fore-and-aft	
	static	dynamic	static	dynamic
Main and auxiliary machinery	15	22.5	5②	7.5
Safety equipment: e.g. emergency power installations, emergency fire pumps and their device	22.5③	22.5③	10	10

Notes: ① Athwartships and fore-and-aft inclinations may occur simultaneously.

② Where the length of the ship exceeds 100 m, the fore-and-aft static angle of inclination may be taken as $500/L$ degrees, where L = length of the ship, in m.

③ For ships carrying liquefied gases and chemicals, the emergency source of electrical power is also to remain operable with the ship being flooded to a final athwartship inclination up to a maximum of 30°.

1.2.1.3 Main propulsion and steering machinery and auxiliary machinery that is essential to the propulsion and steering, and the safety of the ship are to be capable of operation under the effects of acceleration and motions.

Documented evidence of equipment suitability is to be submitted to CCS according to the following requirements.

(1) Documentation

For ships subject to the SOLAS Convention, ship builders are to identify and document the ship accelerations and motions periods to which machinery and equipment might be subjected to. The expected accelerations and ship motions periods are to be within machinery and equipment manufacturers requirements. The estimations are to consider vessel type, machinery or equipment location and expected service conditions.

(2) Evaluation of equipment suitability

Machinery and equipment manufacturers are to submit the following evidence to the Classification Society to demonstrate that their machinery or equipment can operate under the required conditions stated in 1.2.1.2 and at least at the levels of shipboard accelerations as stated in this paragraph:

① Report of testing under representative conditions; or

② Report of theoretical verification using recognised computational techniques accompanied by detailed and relevant validation data: or

③ Historical data which provides relevant demonstration of satisfactory experience in service.

(3) Installation and operation

Machinery and equipment manufacturers are to submit details of the requirements /recommendations for installation of the machinery and equipment onboard to ensure satisfactory operation in service under the required conditions as described in 1.2.1.2 and at least at the levels of shipboard accelerations as stated in 1.2.1.4 .

Note: Consideration is to be given for positioning machinery in order to minimize the dynamic load on bearings due to ship motion.

Shipbuilders are to submit details demonstrating that the installation of the machinery and equipment onboard is in accordance with manufacturer's requirements /recommendations.

1.2.1.4 The machinery installations relevant to classification of ships are to be so designed and arranged as to ensure normal operation under the ambient temperature conditions as shown in Table 1.2.1.4.

For ships in restricted service, ambient temperature may be taken according to the actual condition of navigation area.

Ambient temperature **Table 1.2.1.4**

Environment	Location	Temperature range (℃)
Air	In enclosed spaces	0 to 45
	Within specific space or on machinery installations	According to actual temperature of specific space or equipment
	On the open deck	-25 to 45
Seawater	All positions	32

1.2.1.5 For the purpose of determining the rating of main and auxiliary reciprocating internal combustion engines, the following ambient reference conditions apply to ships for unrestricted service:

Total barometric pressure	0.1 MPa
Air temperature	45℃
Relative humidity	60%
Sea water temperature (charge air coolant-inlet)	32℃

The engine manufacturers are not expected to provide simulated ambient reference conditions at a test bed.

1.2.1.6 In the case of ships for restricted service, the rating is to be suitable for the temperature conditions associated with the geographical limits of the restricted service.

1.2.2 Vibration

1.2.2.1 The propulsion installations are to be so designed, constructed and installed that any mode of their vibrations is not to cause undue stresses in them in the normal operating ranges.

1.2.3 Strengthening for navigation in ice

1.2.3.1 For ships navigating in ice and granted relevant additional notations, their main propulsion machinery and auxiliary equipment are to comply with the provisions of Chapter 14 of this PART.

1.2.4 Astern power

1.2.4.1 In order to maintain sufficient manoeuvrability and secure control of the ship in all normal

circumstances, the main propulsion machinery is to be capable of reversing the direction of thrust so as to bring the ship to rest from the maximum service speed. The main propulsion machinery is to be capable of maintaining in free route astern at least 70% of the ahead revolution.

1.2.4.2 Where steam turbines are used for main propulsion, they are to be capable of maintaining in free route astern at least 70% of the ahead revolution for a period of at least 15 min. The astern trial is to be limited to 30 min or in accordance with manufacturer's recommendation to avoid overheating of the turbine due to the effects of "windage" and friction.

1.2.4.3 For the main propulsion systems with reversing gears, controllable pitch propellers or electric propeller drive, running astern is not to lead to the overload of propulsion machinery.

1.2.4.4 Main propulsion systems are to undergo tests to demonstrate the astern response characteristics. The tests are to be carried out at least over the manoeuvring range of the propulsion system and from all control positions. A test plan is to be provided by the yard and accepted by the surveyor. If specific operational characteristics have been defined by the manufacturer these are to be included in the test plan①.

1.2.4.5 The reversing characteristics of the propulsion plant, including the blade pitch control system of controllable pitch propellers, are to be demonstrated and recorded during trials②.

1.2.5 Overload power

1.2.5.1 Prime movers of main engines and electric generators are to be capable of running at an overload power corresponding to 110% of its rated power.

1.2.6 Dead ship starting

1.2.6.1 Ship's machinery is to be so arranged that it can be brought into operation from the dead ship condition using only the facilities available on board without external aid.

Dead ship condition is to be understood to mean a condition under which the main propulsion plant, boilers and auxiliaries are not in operation and in restoring the propulsion, no stored energy for starting and operating the propulsion plant, the main source of electrical power and other essential auxiliaries is assumed to be available.

Where the emergency source of power is an emergency generator which complies with 9.5.3 of this PART and 2.2.1.6 of PART FOUR of the Rules, this generator may be used for restoring operation of the main propulsion plant, boilers and auxiliaries where any power supplies necessary for engine operation are also protected to a similar level as the starting arrangements.

Where there is no emergency generator installed or an emergency generator does not comply with the above-mentioned requirements, the arrangements for bringing main and auxiliary machinery into operation are to be such that the initial charge of starting air or initial electrical power and any power supplies for engine operation can be developed on board ship without external aid. If for this purpose an emergency air compressor or an electric generator is required, these units are to be powered by a hand-starting oil engine or a hand-operated compressor.

The arrangements for bringing main and auxiliary machinery into operation are to have capacity such that the starting energy and any power supplies for engine operation are available within 30 min of a dead ship condition. For steam main propulsion unit, 30 min means time from dead ship condition to successful ignition of first main boiler.

1.2.7 Automation of machinery installations

1.2.7.1 Automatioin for machinery installations is to comply with the relevant requirements of PART SEVEN of the Rules.

1.2.8 Materials

1.2.8.1 The materials used in the construction of main components for main propulsion and auxiliary machinery installations and propulsion shafting systems, boilers and pressure vessels are to be in compliance with the relevant requirements of CCS Rules for Materials and Welding.

1.2.8.2 For all ships, new installation of materials which contain asbestos are prohibited.

1.2.9 Fuel

---

① This paragraph applies to:
(1) ships contracted for construction on or after 1 July 2018.
(2) ships other than those specified in the preceding (1) on which astern testing is carried out in accordance with 5.9.4.10, Chapter 5, PART ONE of the Rules on or after 1 July 2018.

② Same as ① above.

1.2.9.1 The flash point (closed cup test) of oil fuel for the main propulsion machinery and prime movers to drive generators or boilers are, in general, not to be less than 60℃ For the prime movers of emergency generators, oil fuel having a flash point of not less than 43℃ is permissible.
1.2.9.2 The use of oil fuel having a flashpoint of less than 60℃ but not less than 43℃ may be permitted (e.g. for feeding the emergency fire pump's engines and the auxiliary machines which are not located in the machinery spaces of category A) subject to the following:
(1) fuel oil tanks except those arranged in double bottom compartments are to be located outside of machinery spaces of category A;
(2) provision for the measurement of oil temperature are to be provided on the suction pipe of the oil fuel pump;
(3) stop valves and/or cocks are provided on the inlet side and outlet side of the oil fuel strainers;
(4) pipe joints of welded construction or of circular cone type or spherical type union joint are to be applied as much as possible;
(5) the whole fuel system is to be located outside the machinery spaces of category A;
(6) the arrangement of fuel oil tank is to comply with the requirements of 3.2.1.5(1)-(5) of Chapter 3 of PART SIX of the Rules.
1.2.9.3 In cargo ships the use of fuel having a lower flashpoint than 43℃ may be permitted provided that such fuel is not stored in any machinery space and the arrangement for the complete installation has been submitted for approval.
1.2.9.4 Ships using distillates with a sulphur content not more than 0.10% m/m are to comply with the relevant requirements of this PART and in addition, the requirements of CCS Guidelines for Use of Low Sulphur Distillate Fuels in Ships.

1.2.10 Emission treatment
1.2.10.1 Ships installed with exhaust gas cleaning systems (hereinafter referred to as the EGC systems) for reduction of SO_x emission from fuel oil combustion units are, in addition to the relevant provisions of this PART, to comply with the requirements of CCS Guidelines for Testing and Survey of Exhaust Gas Cleaning Systems and Guidelines for Design and Installation of Exhaust Gas Cleaning Systems.
1.2.10.2 Ships installed with selective catalytic reduction systems (hereinafter referred to as the SCR systems) for reduction of NO_x emission from diesel engines are, in addition to the relevant provisions of this PART, to comply with the requirements of CCS Guidelines for Approval and Survey of Selective Catalytic Reduction (SCR) systems and Guidelines for Application of Selective Catalytic Reduction (SCR) Systems Onboard Ships.
1.2.10.3 Ships installed with exhaust gas recirculation systems (hereinafter referred to as the EGR systems) and related auxiliary systems for reduction of NOx emission from diesel engines are, in addition to the relevant provisions of this Part, to comply with the requirements of CCS Guidelines for Application of Exhaust Gas Recirculation Systems onboard Ships.

1.2.11 Clean energy and power
1.2.11.1 Ships other than liquefied gas carriers using natural gas as fuel are, in addition to the relevant provisions of this PART, to comply with relevant requirements of the Rules for Natural Gas Fuelled Ships.
1.2.11.2 Liquefied gas carriers using natural gas as fuel are, in addition to the relevant provisions of this PART, to comply with relevant requirements of the Guidelines for Design and Installation of Gas Fuel Engine Systems of Liquefied Gas Carriers.
1.2.11.3 Liquefied gas carriers using liquefied gas other than natural gas as fuel are, in addition to the relevant provisions of this PART, to comply with relevant requirements of 16.9, Chapter 16, PART THREE of CCS Rules for Construction and Equipment of Ships Carrying Liquefied Gases in Bulk.
1.2.11.4 Ships using methyl/ethyl as fuel are, in addition to the relevant provisions of this PART, to comply with relevant requirements of CCS Guidelines for Ships Using Methanol/Ethanol Fuel.
1.2.11.5 Ships using biodiesel fuel or the mixture of biodiesel and regular fuel as fuel are, in addition to the relevant provisions of this PART, to comply with relevant requirements of CCS Guidelines for Ships Using Biofuel.
1.2.11.6 Ships provided with the fuel cell power system are, in addition to the relevant provisions of this PART, to comply with relevant requirements of CCS Guidelines for Ships Using Fuel Cell Power Installations.
1.2.11.7 Ships using liquefied petroleum gas as fuel are, in addition to the relevant provisions of this PART, to comply with relevant requirements of CCS Guidelines for Ships Using Liquefied Petroleum Gas Fuel.
1.2.11.8 Ships using ammonia as fuel are, in addition to the relevant provisions of this PART, to comply

with relevant requirements of CCS Guidelines for Ships Using Ammonia Fuel.

1.2.12 Trials

1.2.12.1 The mooring and sea trials for machinery installations are to be carried out in accordance with the relevant provisions of the Rules and the approved test programs.

On completion of the trials, corresponding technical documents and trial reports are to be furnished by the shipyard.

Section 3 ARRANGEMENT

1.3.1 Means of escape

1.3.1.1 Means of escape in machinery spaces are to comply with the requirements specified in PART SIX of the Rules.

1.3.2 Boiler arrangement

1.3.2.1 Where boilers are located in machinery spaces on tween-decks and the boiler rooms are not separated from the machinery spaces by watertight bulkheads, the tween-decks are to be provided with coamings at least 200 mm in height to prevent the oily water that might leak from spreading and dropping to the lower level. This area may be drained to the bilges. The drain tank is not to form part of an overflow system.

1.3.2.2 The clearance between boilers and fuel oil tank boundaries is not to be less than that specified in Table 1.3.2.2.

The clearance between boilers and fuel oil tank boundaries (mm) Table 1.3.2.2

		Top plate of double-bottom fuel oil tank	Fuel oil bulkhead
Water-tube boiler	Outer wall	—	450
	Bottom	600	—
Fire-tube boiler	End plate	—	600
	Bottom	450	—

1.3.3 Skylights of machinery casings

1.3.3.1 Skylights located in machinery spaces of category A are to be of steel and are not to contain glass panels. Suitable arrangements are to be made to permit the release of smoke in the event of fire, from the space to be protected.

1.3.4 Ventilation

1.3.4.1 Machinery spaces are to be adequately ventilated so as to ensure that when machinery or boilers therein are operating at full power in all weather conditions including heavy weather, an adequate supply of air is maintained to the spaces for the safety and comfort of personnel and the operation of the machinery.

1.3.4.2 All spaces, where flammable or toxic gases or vapors may accumulate, are to be provided with adequate ventilation.

1.3.5 Position of emergency equipment on passenger ships

1.3.5.1 Emergency sources of electrical power, fire pumps, bilge pumps except those specifically serving the spaces forward of the collision bulkhead, any fixed fire-extinguishing system required in PART SIX of the Rules and other emergency installations which are essential for the safety of the ship, except anchor windlasses, are not to be installed forward of the collision bulkhead.

1.3.6 Protection

1.3.6.1 In places where the working of machinery and equipment may cause injuries to the operating personnel, handrails, protecting casings or screens are to be provided.

1.3.6.2 Placards or labels are to be provided for illustrating the correct procedures of operation, so as to avoid any mistakes in the operation or change-over of the machinery or systems.

1.3.6.3 All surfaces of machinery and pipes where the hot surfaces may injure personnel are to be protected by handrails or shields. Where the surface temperature may exceed 220℃, they are to be effectively shielded to prevent ignition caused by flammable liquids. Where the insulation covering these surfaces is oil-absorbing or previous to oil, such insulation is to be encased in steel or equivalent.

1.3.7 Communication

1.3.7.1 At least two independent means are to be provided for communicating orders from the navigating bridge to the position in the machinery space or in the control room from which the engines are normally controlled: one of these is to be an engine-room telegraph which provides visual indication of the orders and responses both in the machinery space and in the navigation bridge. Appropriate means of communication is to be provided from the navigation bridge and the engine-room to any other positions from which the speed of direction of thrust of the propellers may be controlled.

1.3.8 Accessibility

1.3.8.1 Accessibility, for the purposes of control, maintenance, inspection and repair of various machinery and equipment, is to be provided in machinery and boiler spaces.

1.3.9 Stuffing boxes for shaftings

1.3.9.1 Stuffing boxes are to be fitted on the watertight bulkhead of the engine room where the shafts pass through. They are to be so arranged as to be convenient for tightening and renewing the packings from the engine room side. The fore sealing ends of the stern tubes as well as the plummer blocks are to be easily accessible for maintenance.

1.3.10 Earthing

1.3.10.1 Suitable earthing arrangements are to be provided to prevent excessive electrical potential difference between the crankshaft/shafting of main propulsion diesel engines and hull.

CHAPTER 2 PUMPING AND PIPING SYSTEMS

Section 1 GENERAL PROVISIONS

2.1.1 General requirements

2.1.1.1 Unless otherwise stated, this Chapter applies to piping systems of all ships. Chemical cargo piping, chemical process piping, liquefied gases cargo piping, liquefied gases process piping and fuel piping such as liquefied natural gas, liquefied petroleum gas, ammonia, methanol/ethanol, etc. are to satisfy relevant requirements of applicable CCS rules and guidelines such as Rules for Construction and Equipment of Ships Carrying Dangerous Chemicals in Bulk, Rules for Construction and Equipment of Ships Carrying Liquefied Gases in Bulk, Rules for Ships Using Natural Gas Fuels, Guidelines for Ships Using Liquefied Petroleum Gas as Fuel, Guidelines for Ships Using Ammonia as Fuel, and Guidelines for Ships Using Methanol/Ethanol as Fuel, respectively.

2.1.1.2 The certification requirements and product survey of pumps, pipes, valves and fittings in piping systems are to comply with the relevant requirements specified in Chapter 3 of PART ONE of the Rules.

2.1.2 Plans and documents

2.1.2.1 For all ships, the following plans and documents are to be submitted for approval:

(1) arrangement of machinery and boiler spaces;
(2) bilge piping and ballast piping;
(3) arrangement of air pipes, sounding pipes and overflow pipes;
(4) fuel oil feeding system for main and auxiliary engines and boilers;
(5) fuel oil transfer system;
(6) lubricating oil piping for main and auxiliary engines;
(7) cooling water piping system for main and auxiliary engines;
(8) compressed air piping system;
(9) steam piping;
(10) condensate and exhaust steam piping;
(11) boiler feed and blow-off piping;
(12) oil fuel heating piping;
(13) purgative system for fuel oil and lubricating oil;
(14) exhaust gas piping for main and auxiliary engines;
(15) arrangement of ventilation pipes for engine room;
(16) hydraulic systems;
(17) arrangement of drain pipes;
(18) additional plans and documents as may be deemed necessary by CCS.

2.1.2.2 For oil tankers, the following plans and documents are to additionally be submitted for approval:

(1) cargo oil piping system;
(2) bilge piping system of cargo pump rooms and cofferdams;
(3) cargo oil heating piping;
(4) arrangement of venting systems (including purge, gas-free systems);
(5) closed ullage system (where applied);
(6) arrangement of cargo pump tank.

2.1.2.3 For all ships, the following plans and documents are to be submitted for information (if relevant information is reflected in the submitted plans, submission of following plans and documents is not necessary):

(1) specifications of machinery installations;
(2) particulars of machinery equipment;
(3) calculations of machinery equipment.

2.1.2.4 The materials, sizes, types, design pressures and design temperatures of pipes, valves and fittings, and the set pressure of safety valves are to be clearly marked on plans. Where separate calculations are not submitted, necessary rule calculations are to be affixed to the plans.

2.1.3 Design pressure

2.1.3.1 The design pressure for piping is the maximum permissible working pressure and it is not to be less than the highest set pressure of any safety valve or relief valve.

2.1.3.2 For pipes containing fuel oil, the design pressure is to be taken as given in Table 2.1.3.2.

Design pressure for pipes containing fuel oil **Table 2.1.3.2**

Working temperature / Working pressure	T ≤ 60℃	T > 60℃
P ≤ 0.7 MPa	0.3 MPa or highest working pressure, whichever is greater	0.3 MPa or highest working pressure, whichever is greater
P > 0.7 MPa	Highest working pressure	1.4 MPa or highest working pressure, whichever is greater

2.1.3.3 For special cases, the design pressure is to be specially considered.

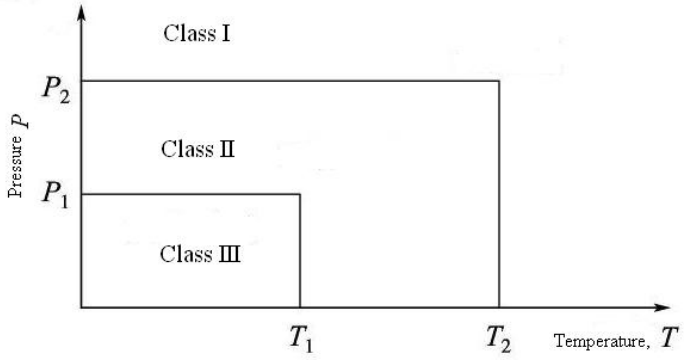
2.1.4 Design temperature

2.1.4.1 The design temperature is to be taken as the maximum temperature of the internal fluid.
In the case of pipes for superheated steam, the temperature is to be taken as the designed operating steam temperature for the pipeline, provided that the temperature at the superheater outlet is closely controlled. Where temperature fluctuations exceeding 15℃ above the designed temperature are expected in normal service, the steam temperature to be used for determining the allowable stress is to be increased by the amount of this excess. For special cases, the design temperature is to be specially considered.

2.1.5 Classes of pipes

2.1.5.1 For the purpose of assigning appropriate testing requirements, types of joints to be adopted, heat treatment and weld procedure, pressure piping systems are divided into three classes in accordance with their design pressure and design temperature, as indicated in Table 2.1.5.1.

Piping system class **Table 2.1.5.1**



Piping system	Class I		Class II		Class III	
	Design pressure > P_2 (MPa)	Design temperature > T_2 (℃)	Design pressure ≤ P_2 (MPa)	Design temperature ≤ T_2 (℃)	Design pressure ≤ P_1 (MPa)	Design temperature ≤ T_1 (℃)
Steam	> 1.6	or > 300	≤ 1.6	and ≤ 300	≤ 0.7	and ≤ 170
Thermal oil	> 1.6	or > 300	≤ 1.6	and ≤ 300	≤ 0.7	and ≤ 150
Fuel oil, lub-oil, flammable hydraulic oil	> 1.6	or > 150	≤ 1.6	and ≤ 150	≤ 0.7	and ≤ 60
Other media	> 4.0	or > 300	≤ 4.0	and ≤ 300	≤ 1.6	and ≤ 200

Notes:

① For Class I piping, one parameter for design pressure and design temperature of Class I specified in the Table is to be met; For Class II or Class III piping, both the parameters for design pressure and design temperature specified in the Table are to be met.

② Toxic or corrosive media, flammable media heated above flash point or with flash point below 60℃ media and liquefied gas belong to class I. If means of special safeguards for preventing leakage and its consequences are provided (e.g. pipes led in positions where leakage of internal fluids will not cause a potential hazard or damage to surrounding areas which may include the use of pipe ducts, shielding, screening etc.), they may also belong to class II, but except toxic media.

③ Cargo pipes belong to class III.

④ Class III pipes may be used for open ended piping, e.g. drains, overflows, vents boiler waste steam pipes, etc.
⑤ Other media mean air, gases, water, and non-flammable hydraulic oil and urea for the selective catalytic reduction (SCR) system (when the piping material is selected according to ISO 18611-3:2014), etc.
⑥ Thermal oil means the circulating oil used in the thermal oil system as specified in Section 8, Chapter 4 of this PART; in addition, the oxygen and acetylene piping is to be Class I piping (except for discharge pipes with openings).

2.1.6 Materials

2.1.6.1 Materials to be used for pipes, valves and fittings are to be suitable for the medium and service for which the piping is intended. In the case of especially corrosive media, the material for the piping system is to be taken into consideration in each particular case.
2.1.6.2 Material for pipes, valves and relative fittings belonging to Classes I and II and for valves and pipes fitted on the ship's side and for valves fitted on the collision bulkhead are to be tested in accordance with the relevant requirements of CCS Rules for Materials and Welding.
2.1.6.3 Materials for pipes, valves and fittings of Class III are to be tested in accordance with applicable standards.

Section 2 CARBON, LOW ALLOY STEELS AND stainless steelS

2.2.1 Carbon and low alloy steel pipes, valves and fittings

2.2.1.1 Classes I and II pipes are to be seamless steel pipes or welded pipes fabricated with a welding procedure approved by CCS.
2.2.1.2 In general, carbon and carbon-manganese steel pipes, valves and fittings are not to be used for medium temperatures above 400℃. Nevertheless, they may be used for higher temperatures if their metallurgical behavior and time dependent strength (UTS after 100,000 h) are in compliance with national or international codes or standards and if such values are guaranteed by the steel manufacturer.
Special alloy steel pipes, valve and fittings are to be employed according to the relevant requirements of CCS Rules for Materials and Welding.

2.2.2 Calculation of wall thickness

2.2.2.1 The minimum wall thickness δ of steel pipes subject to internal pressure is not to be less than that determined by the following formula[①]:

$$\delta = \delta_0 + b + c \quad \text{mm}$$

where: δ_0 — the basic wall thickness, in mm, see 2.2.2.2 of this Section;
b — allowance for bending, in mm. The value for this allowance is to be chosen in such a way that the calculated stress in the bend, due to the internal pressure only, does not exceed the permissible stress. When this allowance is not determined by a more accurate procedure, it is to be taken according to 2.2.2.3 of this Section;
c — corrosion allowance, in mm, to be obtained from Table 2.2.2.1.

Corrosion allowance *C* for steel pipes **Table 2.2.2.1**

Usage of piping	*C*	Usage of piping	*C*
Overheat steam piping	0.3	Lubricating oil piping	0.3
Saturated steam piping	0.8	Fuel oil piping	1.0
Steam heating piping in cargo tank	2.0	Cargo oil piping	2.0
Boiler open-type feed piping	1.5	Refrigerant piping of refrigerating installation	0.3
Boiler close-type feed piping	0.5	Fresh water piping	0.8
Boiler blow-off piping	1.5	Sea water piping	3.0
Compressed air piping	1.0	Salt water piping in refrigerated hold	2.0
Hydraulic oil piping	0.3		

For pipes passing through tanks, an additional corrosion allowance is to be taken, depending on the external medium, in order to account for the external corrosion. Where pipes and any integral pipe joints are efficiently protected against corrosion by means of coating, lining, etc., the corrosion allowance may be reduced by not more than 50%. In the case of use of special alloy steel with sufficient corrosion resistance, the corrosion allowance may be reduced, even to zero.
2.2.2.2 The basic wall thickness δ_0 for steel pipes is to be determined by the following formula:

① The formula applies to pipes where the ratio outside-diameter to inside-diameter does not exceed the value 1.7.

$$\delta_0 = \frac{pD}{2[\sigma]e + p} \quad \text{mm}$$

where: p — design pressure, in MPa, see 2.1.3 of this Chapter;
D — outside diameter of steel pipes, in mm;
$[\sigma]$ — permissible stress of steel pipes, in N/mm^2, see 2.2.2.4 of this Section;
e — welding efficiency factor. For seamless steel pipes and electric resistance or induction welded steel pipes, e is to be taken as 1; for pipes made by other methods, e will be specially considered.

2.2.2.3 Bending allowance b is not to be less than that determined by the following formula:

$$b = 0.4\ \frac{D}{R}\delta_0 \quad \text{mm}$$

where: R — radius of curvature of a pipe bend at the centre line of the pipe, in mm, in general, R is not to be less than $3D$;
D — outside diameter of steel pipes, in mm;
δ_0 — basic wall thickness, in mm, see 2.2.2.2 of this Section.

2.2.2.4 Permissible stress $[\sigma]$ of steel pipes is to be taken as the lowest of the following values:

$$[\sigma] = \frac{R_m}{2.7} \quad \text{N/mm}^2$$

$$[\sigma] = \frac{R_{eH}^T}{1.6} \quad \text{N/mm}^2$$

$$[\sigma] = \frac{\sigma_D^T}{1.6} \quad \text{N/mm}^2$$

$$[\sigma] = \sigma_c^T \quad \text{N/mm}^2$$

where: R_m — tensile strength of material at room temperature, in N/mm^2;
R_{eH}^T — yield stress or 0.2% proof stress ($R_{p0.2}$) of material at design temperature, in N/mm^2;
σ_D^T — average stress of material to produce rupture in 100,000 h at design temperature, in N/mm^2;
σ_c^T — average stress to produce 1% creep in 100,000 h at the design temperature, in N/mm^2;
$R_m, R_{eH}^T, \sigma_D^T$ are to comply with the relevant requirements of CCS Rules for Materials and Welding. National or international standards may be accepted for R_{eH}^T. σ_c^T may be used as appropriate based on reliable conditions if it is deemed necessary.

2.2.2.5 The minimum wall thickness δ mentioned in 2.2.2.1 above has not taken into account the negative manufacturing tolerance, where there is any negative tolerance allowable in manufacture, the nominal thickness δ_m of pipes is not to be less than that determined by the following formula:

$$\delta_m = \frac{\delta}{1 - \frac{a}{100}} \quad \text{mm}$$

where: a — percentage of negative manufacturing tolerance on thickness.

2.2.2.6 Where the minimum thickness calculated by the formula specified in 2.2.2.5 is less than that shown in Table 2.2.2.6(1), Table 2.2.2.6(2) or Table 2.2.2.6(3), the minimum nominal thickness for the appropriate standard pipe size shown in the Tables is to be used.
For threaded pipes, the thickness is to be measured at the bottom of the thread.

External diameter and minimum nominal thickness for steel pipes, in mm Table 2.2.2.6(1)

External diameter, *D*	Minimum nominal thickness (δ)			
	General pipe③④⑥⑧⑨⑩	Air pipe, overflow pipe and sounding pipe of tank related to hull structure①②③④⑥⑦⑧	Bilge and ballast pipe, general sea water pipe and steam heating coil in liquid tank①③④⑤⑥⑦⑧	Bilge pipe, air pipe, overflow pipe and sounding pipe through ballast tank and fuel oil tank. Ballast pipe through fuel oil tank and fuel oil pipe through ballast tank①②③④⑤⑥⑦⑧
10.2~12	1.6			
13.5~19.3	1.8			
20	2.0			
21.3~25	2.0		3.2	
26.9~33.7	2.0		3.2	
38~44.5	2.0	4.5	3.6	6.3
48.3	2.3	4.5	3.6	6.3
51~63.5	2.3	4.5	4.0	6.3
70	2.6	4.5	4.0	6.3
76.1~82.5	2.6	4.5	4.5	6.3
88.9~108	2.9	4.5	4.5	7.1
114.3~127	3.2	4.5	4.5	8.0
133~139.7	3.6	4.5	4.5	8.0
152.4~168.3	4.0	4.5	4.5	8.8
177.8	4.5	5.0	5.0	8.8
193.7	4.5	5.4	5.4	8.8
219.1	4.5	5.9	5.9	8.8
244.5~273	5.0	6.3	6.3	8.8
298.5~368	5.6	6.3	6.3	8.8
406.4~457	6.3	6.3	6.3	8.8

Notes:

① Where pipes and any integral pipe joints are efficiently protected against corrosion by means of coating, lining, etc., the minimum wall thickness may be reduced by an amount up to 1 mm.

② For sounding pipes, except those for cargo tanks with cargo having a flash point less than 60℃, the minimum wall thickness is intended to apply to the part outside the tank.

③ For threaded pipes, where allowed, the minimum wall thickness is to be measured at the bottom of the thread.

④ The external diameters and thicknesses have been selected from ISO Recommendations R336 for welded and seamless steel pipes. For pipes covered by other Standards, slightly reduced thicknesses may be accepted.

⑤ The minimum wall thickness for bilge lines and ballast lines through deep tanks will be subject to special consideration. The minimum wall thickness for ballast lines through cargo tanks is not to be less than that specified in Table 5.3.4.2 of Section 3, Chapter 5 of this PART.

⑥ The minimum wall thickness for pipes larger than 457 mm nominal size is to be in accordance with a national or international standard and in any case not less than the minimum wall thickness of the appropriate column indicated for 406.4 to 457 mm pipe size in Table 2.2.2.6(1).

⑦ The minimum internal diameters of bilge, sounding, air and overflow pipes are to be:

Bilge 50 mm
Sounding 32 mm
Air and overflow 50 mm

⑧ In general, the minimum thickness listed in this Table is the nominal wall thickness and no allowance need be made for negative tolerance and reduction in thickness due to bending.

⑨ The minimum wall thickness of exhaust gas pipe will be subject to special consideration.

⑩ The minimum wall thickness for cargo oil lines will be subject to special consideration.

External diameter and minimum nominal thickness δ for stainless steel pipes, in mm **Table2.2.2.6(2)**

External diameter (D)	Minimum nominal thickness (δ)
≤10	1.0
11~18	1.5
19~83	2.0
84~169	2.5
170~246	3.0
247~340	3.5
341~426	4.0
427~511	4.5
512~597	5.0

External Diameter and Minimum Nominal Wall Thickness for Austenitic Stainless Steel Pipes, in mm **Table 2.2.2.6(3)**

External diameter (D)	Minimum nominal wall thickness (δ)
10.2 ~ 17.2	1.0
21.3 ~ 48.3	1.6
60.3 ~ 88.9	2.0
114.3 ~ 168.3	2.3
219.1	2.6
273.0	2.9
323.9 ~ 406.4	3.6
> 406.4	4.0

Note: Diameters and thicknesses according to national or international standards may be accepted.

2.2.2.7 The minimum wall thickness of the scuppers and discharge pipes is to comply with the relevant requirements of regulation 22, Annex I to Annex B to the Protocol of 1988 Relating to the International Convention on Load Lines, 1966.

2.2.2.8 The minimum wall thickness of air pipes above the weather deck is to comply with the relevant requirements of 1.12.7.5 of PART TWO of the Rules.

Section 3 COPPER AND COPPER ALLOYS

2.3.1 Copper and copper alloy pipes, valves and fittings

2.3.1.1 Copper and copper alloy pipes used in Classes I and II piping systems are to be seamless.

2.3.1.2 Materials of copper and copper alloys for Class III piping systems are to be manufactured and tested in accordance with the approved standards.

2.3.1.3 In general, copper and copper alloy pipes, valves and fittings are not be used for media having a temperature above the following limits:

copper and aluminum brass: 200℃;

copper nickel: 300℃;

special bronze suitable for high temperature services: 260℃.

2.3.2 Calculation of wall thickness

2.3.2.1 The minimum wall thickness δ of copper and copper alloy pipes subject to internal pressure is not to be less than that determined by the following formula①:

$$\delta = \delta_0 + b + c \quad \text{mm}$$

where: δ_0 — the basic wall thickness, in mm, see 2.3.2.2 of this Section;

b — allowance for bending, in mm. The value for this allowance is to be chosen in such a way that the calculated stress in the bend, due to the internal pressure only, does not exceed the permissible stress. When this allowance is not determined by a more accurate procedure, it is to be taken according to 2.3.2.3 of this Section;

c — corrosion allowance, in mm; for copper, brass and similar alloys, copper-tin alloys except those with lead contents, and copper-nickel alloys where the nickel content is less than 10%, c = 0.8 mm; copper-nickel alloys where the nickel content is 10% or greater, c = 0.5

① The formula applies to pipes where the ratio outside-diameter to inside-diameter does not exceed the value 1.7.

mm; where the media are non-corrosive relative to the pipe material, $c = 0$.

2.3.2.2 The basic wall thickness of copper and copper alloy pipes is to be determined by the following formula:

$$\delta_0 = \frac{pD}{2[\sigma]e + p} \quad \text{mm}$$

where: p — design pressure, in MPa, see 2.1.3 of this Chapter;
D — outside diameter of pipe, in mm;
$[\sigma]$ — permissible stress, in N/mm^2, obtained from Table 2.3.2.2;
e — efficiency factor, $e = 1$ for seamless copper pipes and for welded copper pipes delivered by manufacturers approved for making welded copper pipes which are considered an equivalent to seamless copper pipes. For copper pipes made by other methods, e will be specially considered.

Allowable stress of copper and copper alloy pipes [σ] **Table 2.3.2.2**

Materials	Material condition	Tensile strength (N/mm^2)	Allowable stress (N/mm^2)										
			Design temperature (℃)										
			50	75	100	125	150	175	200	225	250	275	300
copper	annealing	215	41	41	40	40	34	27.5	18.5	—	—	—	—
Aluminum brass	annealing	325	78	78	78	78	78	51	24.5	—	—	—	—
copper-nickel alloys CuNi5Fe1Mn CuNi10Fe1Mn	annealing	275	68	68	67	65.5	64	62	59	56	52	48	44
copper-nickel alloys CuNi30	annealing	365	81	79	77	75	73	71	69	67	65.5	64	62

Notes:
① If the metal temperature is between the values listed in the Table, allowable stress may be determined by linear interpolation.
② The allowable stresses of materials not covered by the Table are to submit detailed information.

2.3.2.3 Bending allowance b is not to be less than that determined by the following formula:

$$b = 0.4\frac{D}{R}\delta_0 \quad \text{mm}$$

where: R — radius of curvature of a pipe bend at the centre line of the pipe, in mm. In general, R is not to be less than $3D$;
D — outside diameter of pipe, in mm;
δ_0 — basic wall thickness, in mm, see 2.3.2.2 of this Section.

2.3.2.4 The minimum wall thickness δ mentioned in 2.3.2.1 above has not taken into account the negative manufacturing tolerance, where there is any negative tolerance allowable in manufacture, the nominal thickness of pipes is not to be less than that determined by the following formula:

$$\delta_m = \frac{\delta}{1 - \frac{a}{100}} \quad \text{mm}$$

where: a — percentage of negative manufacturing tolerance on thickness.

2.3.2.5 Where the minimum wall thickness calculated by the formula specified in 2.3.2.4 is less than that shown in Table 2.3.2.5, the minimum nominal thickness for the appropriate standard pipe size shown in the Table is to be used.
For threaded pipes, the thickness is to be measured at the bottom of the thread.

External diameter and minimum nominal thickness δ_m for copper and copper alloy pipes, in mm **Table 2.3.2.5**

Outside diameter (D)	Minimum nominal thickness (δ_m)	
	Copper	Copper alloys
8~10	1.0	0.8
12~20	1.2	1.0
25~44.5	1.5	1.2
50~76.1	2.0	1.5
88.9～108	2.5	2.0
133～159	3.0	2.5

Outside diameter (D)	Minimum nominal thickness (δ_m)	
	Copper	Copper alloys
193.7～267	3.5	3.0
273～470	4.0	3.5
508	4.5	4.0

Notes:
① The outside diameters and the thickness have been selected from ISO Standards.
② For pipes covered by other standards, slightly reduced thickness may be accepted.

Section 4 OTHER MATERIALS

2.4.1 Grey cast iron pipes, valves and fittings

2.4.1.1 Grey cast iron pipes, valves and fittings are not to be used in Class I and Class II piping systems. Grey cast iron valves and fittings may be used in Class II steam piping but the design temperature does not exceed 220℃.

2.4.1.2 Grey cast iron pipes, valves and fittings may, in general, be accepted in Class III piping systems, in cargo lines within cargo tanks of tankers , but grey cast iron is not to be used for the following:

(1) cargo oil pipelines having pressures exceeding 1.6 MPa on weather decks of oil tankers;
(2) pipes, valves and fittings intended for conveying media having temperatures above 220℃;
(3) piping may be subjected to pressure shock, excessive strains and vibration;
(4) ship-side valves and fittings and sea valves, pipes fitted on the ship sides and sea chest;
(5) valves fitted on the collision bulkhead;
(6) valves under static head fitted on the outside of fuel tank walls;
(7) boiler blow-off systems;
(8) pipes for steam, fire extinguishing, bilge and ballast systems.

Grey cast iron may be accepted for pressures up to 1.6 MPa for cargo oil pipe lines on weather decks of oil tankers except for manifolds and their valves and fittings connected to cargo handling hoses.

2.4.2 Nodular graphite cast iron pipes, valves and fittings

2.4.2.1 Ferritic nodular graphite iron castings for pipes, valves and fittings in Class II and Class III piping systems are to be made in a grade having a specified minimum elongation not less than 12% on a gauge length of $5.65\sqrt{S_0}$, where S_0 is the cross-sectional area of the test piece.

2.4.2.2 Ferritic nodular graphite iron pipes, valves and fittings may be accepted for bilge, ballast and cargo oil piping.

2.4.2.3 Ferritic nodular graphite cast iron pipes, valves and fittings are not to be used in piping systems for conveying media having temperatures exceeding 350℃.

2.4.2.4 Where ferritic nodular graphite iron castings are used for ship-side pipes, valves and fittings, the properties of this material are to comply with the relevant requirements of CCS Rules for Materials and Welding.

2.4.2.5 Where the elongation is less than the minimum required in 2.4.2.1 of this Section, the material is to be subject to the same limitations as grey cast iron.

2.4.3 Plastic pipes

2.4.3.1 The ranges and locations of plastic pipes used in ships are to comply with the provisions in Table 1 of Appendix I, and the plastic pipes are to comply with the fire endurance requirements in the Table.

2.4.3.2 Plastic pipes used on ships are to be selected in relation to their chemical composition, physical and mechanical properties, and temperature limits.

2.4.3.3 Plastic pipes are in general not to be used for media with a temperature above 60℃ or below 0℃.

2.4.3.4 Plastic pipes used on ships are to be designed, manufactured, used and test in accordance with the relevant requirements in Appendix 1 of this Chapter.

2.4.4 Flexible hoses

2.4.4.1 Flexible hoses mean short length of metallic or non-metallic hoses normally with prefabricated end fittings ready for installation.

2.4.4.2 Flexible hoses may be used for a permanent connection between a fixed piping system and items of machinery, as well as temporary connection between portable equipment and pipes.

2.4.4.3 Flexible hoses are to be designed, manufactured, used and tested in accordance with the relevant

requirements of Appendix 2 of this Chapter.

Section 5 CONNECTION OF PIPE LENGTHS, HEAT TREATMENT AND NON-DESTRUCTIVE TESTING

2.5.1 Connection of pipe lengths

2.5.1.1 Direct connection of pipe lengths may be obtained by:

(1) welded butt-joints between pipes or between pipes and valve chests or other fittings, the welded butt-joints are to be of full penetration type with or without special provisions for the quality of root side①;

(2) slip-on sleeve welded joints, the slip-on sleeve welded joints are to have sleeves and relative welding of adequate dimensions conforming to the recognized standard;

(3) threaded sleeve joints of approved type;

(4) mechanical joints.

2.5.1.2 The application of the aforesaid types of connection is as follows:

(1) Welded butt-joints and slip-on sleeve welded joints are to comply with the requirements specified in Table 2.5.1.2(1).

Connection of pipe length **Table 2.5.1.2(1)**

Type of connection	Allowed for classes	Allowed for outside diameter
Butt welded joints with special provision for a high quality of root side	I, II, III	No restriction
Butt welded joints without special provision for a high quality of root side	II, III	
Slip-on sleeve welded joints	III	
	I, II, except for piping systems conveying toxic media where fatigue, severe erosion or crevice corrosion is expected to occur	$D \leq 88.9$ mm

(2) Slip-on threaded joints are to comply with requirements of a recognized standard. Slip-on threaded joints may be used for outside diameters as stated below except for piping systems conveying toxic or flammable media or services where fatigue, severe erosion or crevice corrosion is expected to occur. Slip-on threaded joints with outside diameters of maximum 25mm may be used for connecting small bore instrumentation equipment (e.g., pressure/temperature sensors) to piping systems conveying flammable media. Threaded joints in CO_2 systems are to be allowed only inside protected spaces and in CO_2 cylinder rooms.

① Threaded joints for direct connectors of pipe lengths with tapered thread may be allowed for Class I, outside diameter not more than 33.7 mm as well as Class II and Class III, outside diameter not more than 60.3 mm.

② Threaded joints for parallel thread may be allowed for Class III, outside diameter not more than 60.3 mm.

③ In particular cases, sizes in excess of those mentioned above may be accepted if they satisfy the requirements of recognized international or national standards.

2.5.2 Flange connections

2.5.2.1 Typical flange connections are indicated in Figure 2.5.2.1.

Slip-on joints, sleeve threaded joints and other types of direct connection of pipe lengths (e.g. bell and spigot joints) may be allowed in each particular case for small diameter and depending upon the service conditions.

2.5.2.2 The above-mentioned types of flange connections are to be selected in accordance with the requirements specified in Table 2.5.2.2.

Application of typical flange connections **Table 2.5.2.2**

Piping class	Toxic or corrosive media④, flammable media④, liquefied gas	Lubricating oil and fuel oil	Steam③ and hot oil	Other media①②③
I	A,B⑥	A,B	A,B⑥	A,B

① The expression "special provisions for the quality of root side" means that butt welds were accomplished as double welded or by use of a backing ring or inert gas back-up on first pass, or other similar methods accepted by CCS.

II	A,B,C	A,B,C,E⑦	A,B,C,D⑤,E⑤	
III		A,B,C,E	A,B,C,D,E	A,B,C,D,E,F②

Notes:
① Including water, air, other gases, hydraulic oil.
② Type F for water pipes and open ended lines only.
③ Only type A when design temperature exceeds 400℃.
④ Only type A when design pressure exceeds 1 MPa.
⑤ Types D and E are not be used when design temperature exceeds 250℃.
⑥ Type B for outside diameter < 150 mm only.
⑦ Type E for oil piping when design temperature < 150℃ and design pressure < 1.6 MPa only.

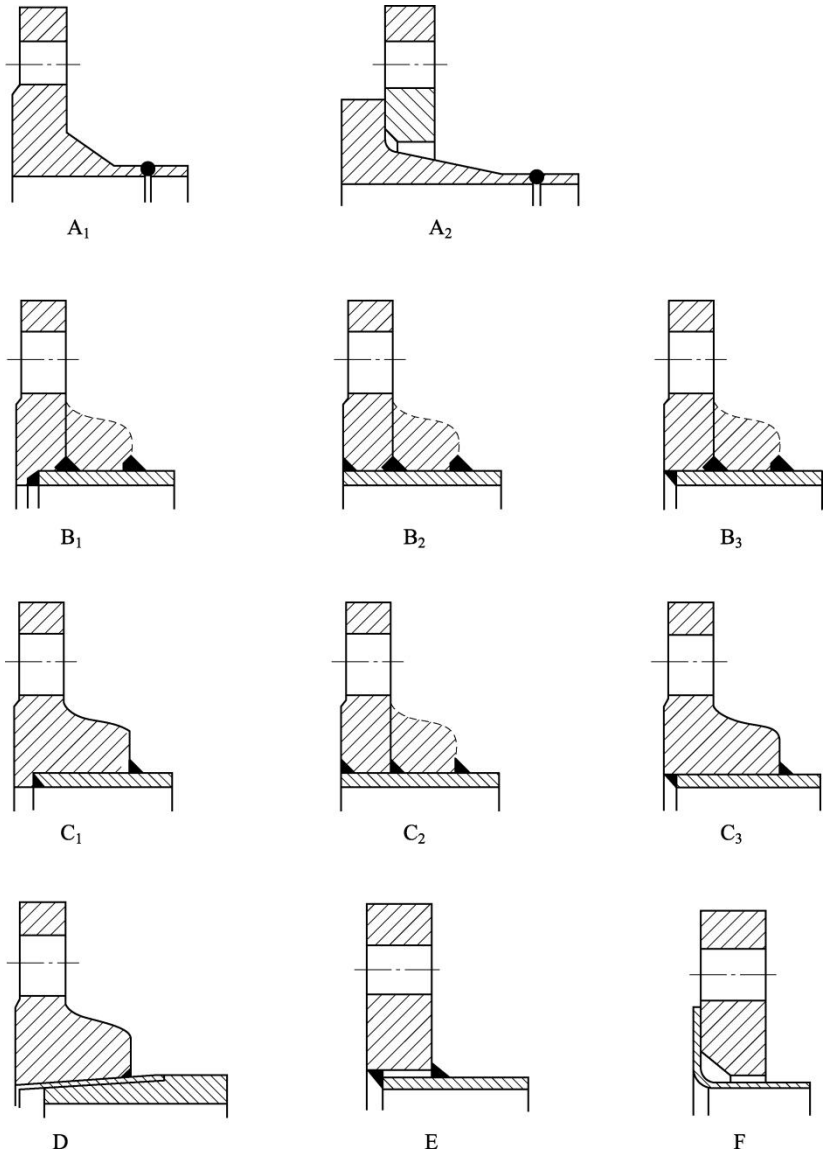


Figure 2.5.2.1 Typical flange connections

Notes: ① For type D, the pipe and flange are to be screwed with a tapered thread and the diameter of the screw portion of the pipe over the thread is not to be appreciably less than the outside diameter of the unthreaded pipe. After the flange has been screwed hard home, the pipe is to be expanded into the flange.
② The leg length of the fillet weld and the penetration of the flange edge, as shown in the Figure, are in general to be 1.5 times the wall thickness of the pipe, but not less than 5 mm.

2.5.2.3 The dimensions of flanges and relative bolts are to be chosen in accordance with the national standards or acceptable standards. For special application, the dimensions of flanges and relative bolts are

to be subject to special consideration①.
Gaskets are to be suitable for the media being conveyed under design pressure and temperature conditions and their dimensions and configuration are to be in accordance with national or acceptable standards.
Flange connections are to be in accordance with national or international standards that are applicable to the piping system and are to recognize the boundary fluids, design pressure and temperature conditions, external or cyclic loading and location.

2.5.3 Mechanical joints

2.5.3.1 The different mechanical joints applicable to this paragraph are indicated in Table 2.5.3.1(1). The mechanical joints are to be subject to type approval based on different usage and location in accordance with the requirements of Appendix 3 of this Chapter.

2.5.3.2 Where appropriate, mechanical joints are to be of fire resistant type as required by Table 2.5.3.1(2). Fire endurance test is specified in 1.5.5(6), Appendix 3 of this Chapter.

2.5.3.3 Material of mechanical joints is to be compatible with the piping material and internal and external media.

2.5.3.4 Application of mechanical joints and their acceptable use for each service is indicated in Table 2.5.3.1(2); dependence upon the Class of piping and pipe dimensions is indicated in Table 2.5.3.1(3).
In particular cases, sizes in excess of those mentioned above may be accepted if in compliance with a recognized national and/or international standard.

2.5.3.5 Where the application of mechanical joints results in reduction in pipe wall thickness due to the use of bite type rings or other structural elements, this is to be taken into account in determining the minimum wall thickness of the pipe to withstand the design pressure.

2.5.3.6 Mechanical joints, which in the event of damage could cause flooding or fire, are not to be used in piping sections directly connected to the ship's side below the bulkhead deck of passenger ships (or freeboard deck of cargo ships) or tanks containing flammable fluids. The number of mechanical joints in flammable fluid systems is to be kept to a minimum. In general, flanged joints conforming to recognized standards are to be used.

2.5.3.7 Mechanical joints in bilge systems of machinery space and higher fire risk space (e.g. cargo pump room and vehicle space) are to be of fire resistant type. For the required fire resistant mechanical joints, see Table 2.5.3.1(2).

2.5.3.8 Mechanical joints are to be tested where applicable, to a burst pressure of 4 times the design pressure. When the design pressure exceeds 20 MPa, the burst pressure will be specially considered.

2.5.3.9 Piping in which a mechanical joint is fitted is to be adequately adjusted, aligned and supported. Supports or hangers are not to be used to force alignment of piping at the point of connection.

2.5.3.10 Slip-on joints are not to be used in pipelines in cargo holds, tanks and other spaces which are not easily accessible (refer to MSC/Circ.734), except that these joints may be permitted in tanks that contain the same media.
Usage of slip type slip-on joints as the main means of pipe connection is not permitted except for cases where compensation of axial pipe deformation is necessary.

2.5.3.11 Mechanical joints are not to be used in the following cases:
(1) bilge piping through ballast tanks and fuel tanks;
(2) sea water and ballast piping (including air and overflow pipes) through cargo holds and fuel tanks;
(3) fuel and oil piping (including air and overflow pipes) through machinery spaces, cargo holds and ballast tanks.

2.5.3.12 The installation of mechanical joints is to be in accordance with the manufacturer's assembly instructions. Where special tools and gauges are required for installation of the joints, these are to be supplied by the manufacturer.

---

① For special applications where the fitting temperature, pressure and size of the flange exceed reliable limits, a complete calculation is to be carried out for bolts and flanges.

Examples of mechanical joints **Table 2.5.3.1(1)**

Pipe unions	
Welded and brazed types	Compression

Notes:
× Application is allowed.
– Application is not allowed.
* Fire endurance test as specified in 1.5.5(6) of Appendix 3 of this Chapter.
Fire resistance capability:
If mechanical joints include any components which readily deteriorate in case of fire, the following footnotes are to be observed:
① Fire endurance test shall be applied when mechanical joints are installed in pump rooms and open decks.
② Slip on joints are not accepted inside machinery spaces of category A or accommodation spaces. May be accepted in other machinery spaces provided the joints are located in easily visible and accessible positions.
③ Approved fire resistant types except in cases where such mechanical joints are installed on open decks, as defined in SOLAS Reg. II-2/9.2.3.3.2.2(10) and not used for fuel oil lines.
④ Fire endurance test shall be applied when mechanical joints are installed inside machinery spaces of category A.
General:
⑤ Only above bulkhead deck of passenger ships and freeboard deck of cargo ships.
⑥ Slip type slip-on joints as shown in Table 2.5.3.1(1) may be used for pipes on deck with a design pressure of 10 bar or less.
⑦ If a connection has passed the “30 min dry” test, it is considered suitable also for applications for which the "8 min dry+22 min wet" and/or "30 min wet " tests are required. If a connection has passed the "8 min dry+22 min wet" test, it is considered suitable also for applications for which the "30 min wet" test is required.

2.5.4 Heat treatment and non-destructive testing

2.5.4.1 The heat treatment and non-destructive testing of piping systems are to comply with the relevant requirements of CCS Rules for Materials and Welding.

Section 6 PUMPS, VALVES AND FITTINGS

2.6.1 Pumps

2.6.1.1 Pumps are to be designed and manufactured according to accepted standards.

2.6.1.2 Hydraulic tests

All components of pumps subject to pressure are to be subject to hydraulic tests in workshop prior to assembly. The hydraulic test pressure is to be 1.5 times the design pressure, but need not exceed the design pressure plus 7 MPa.

For centrifugal pumps, the design pressure is to be taken as the maximum pressure head on the performance curve. For displacement pumps, the design pressure is to be taken as the relief valve setting pressure.

For steam driven pumps, the test pressure at the steam side is to be 1.5 times the steam working pressure.

---

① This requirement is applicable to any mechanical pipe joints submitted for approval from 1 January 2020 and to any renewal of type approval of existing design of mechanical pipe joint after 1 January 2020.

2.6.1.3 Capacity tests
Pump capacities are to be checked with the pump operating at design conditions (rated speed and pressure head). For centrifugal pumps, the pump characteristic (head-capacity) design curve is to be verified to the satisfaction of the Surveyor.
Capacity tests may be waived if previous satisfactory tests have been carried out on similar pumps.
2.6.1.4 Relief valve capacity test
For positive displacement pumps with an integrated relief valve, the valve's setting and full flow capacity corresponding to the pump maximum rating is to be verified.
The operational test for relief valve capacity may be waived if previous satisfactory tests have been carried out on similar pumps.

2.6.2 Valves and fittings
2.6.2.1 Valves are to be designed and manufactured according to accepted standards. For other structurally new-type valves or non-standard valves, detailed drawings and information are to be submitted.
2.6.2.2 The strength of valves and fittings in piping system is to be appropriate to the strength required by the connected pipes and is to be able to work efficiently under the maximum working pressure. Valves are to be made of steel, cast iron, copper, copper alloy or other materials suitable for the intended service.
2.6.2.3 All valves are to be so constructed as to prevent the possibility of valve bonnets or glands being slackened back or loosened when the valves are operated. Screwed-on valve bonnets are not to be used for valves with nominal diameter exceeding 40 mm in Class I and Class II piping systems, sea valves, ship-side valves and valves in flammable liquid system.
2.6.2.4 Valves on board ships are to be of such construction that the closing of which is obtained by clockwise rotation of the hand wheel, and the opening by counter-clockwise rotation.
2.6.2.5 Indicators are to be provided to show the open and closing condition of the valves, unless this can be observed in some other way; for remotely controlled valves, the remote control position is also to show the open and closing condition of the valve.
2.6.2.6 Valves and cocks are to be fitted with nameplates to indicate their purposes. The casing of non-return valves is to be permanently marked with flow direction.
2.6.2.7 The welded necks on the valve bodies are to be long enough to ensure that the valves will not deform due to welding and subsequent heat treatment of the joints.
2.6.2.8 All valves are to be subject to hydraulic tests in workshop. The hydraulic test pressure is to be 1.5 times the design pressure.

2.6.3 Air pipe closing devices
2.6.3.1 Where air pipes are required by 1.12.7.5 of PART TWO of the Rules to be fitted with automatic closing devices, they are to be designed, manufactured and tested in accordance with the requirements of Appendix 4 of this Chapter.

Section 7 TESTS

2.7.1 Hydraulic tests for piping prior to installation on board
2.7.1.1 All Classes I and II pipes and their associated fittings and, all steam pipes, feed pipes, compressed air pipes and fuel oil pipes having a design pressure greater than 0.35 MPa together with their fittings are to be hydraulically tested after completion of manufacture and before insulating and coating.
2.7.1.2 The hydraulic test pressure P_s is not to be less than that determined by the following formula:

$$P_s = 1.5\,p \qquad \text{MPa}$$

where: p — design pressure, in MPa, see 2.1.3 of this Chapter.

2.7.1.3 For steel pipes and integral fittings for use in systems where the design temperature exceeds 300℃, test pressure P_s is to be determined by the following formula, but need not exceed 2 p.

$$P_S = 1.5\frac{[\sigma]_{100}}{[\sigma]_t}p \qquad \text{MPa}$$

where: p — as defined in 2.7.1.2;
$[\sigma]_{100}$ — permissible stress for 100℃, in N/mm^2;
$[\sigma]_t$ — permissible stress for the design temperature, in N/mm^2.

The test pressure may be reduced to 1.5 p where it is necessary to avoid excessive stress in way of bends

and T-connections. In no case is the membrane stress to exceed 90% of the yield stress at the testing temperature.
2.7.1.4 When the hydraulic test of piping is carried out on board, it may be carried out concurrently with the tightness tests required after assembly on board.
2.7.1.5 For pipes with an internal diameter less than 15 mm, the hydraulic test may be waived.
2.7.1.6 When, for technical reasons, it is not possible to carry out complete hydraulic test for all sections piping, prior to assembly on board, applications are to be submitted to CCS for approval for testing the closing lengths of piping, particularly in respect to closing seams.

2.7.2 Hydraulic tests for valves and fittings prior to installation on board

2.7.2.1 Valves and fittings non-integral with the piping system, intended for Classes I and II, are to be hydraulically tested in accordance with recognized standards, but the test pressure is not to be less than 1.5 times the design pressure.
Valves, cocks and distance pieces intended to be fitted on the ship side below the load waterline are to be tested by hydraulic pressure not less than 0.5 MPa.

2.7.3 Testing after assembly on board

2.7.3.1 All piping systems are to be checked for leakage under working conditions.
2.7.3.2 Liquid fuel piping, heating coils in tanks, bilge pipes in way of double bottom tanks or deep tanks and hydraulic piping are to be tested by hydraulic pressure in accordance with Table 2.7.3.2.

Hydraulic tests after assembly on board **Table 2.7.3.2**

Piping system	Test pressure
Liquid fuel piping	1.5 times design pressure, but not less than 0.4 MPa
Heating coils in tanks	
Bilge pipes in way of double bottom tanks or deep tanks	Not less than test pressure of the tank
Hydraulic piping	1.25 times design pressure, but no need to exceed design pressure plus 7 MPa

2.7.3.3 Where Classes I and II pipes are butt welded together during assembly on board, they are to be tested by hydraulic pressure in accordance with the requirements of 2.7.1.1 to 2.7.1.4 after welding. During installation and before the hydraulic test is carried out, the pipe lengths may be insulated, except in way of the joints.
2.7.3.4 The hydraulic test required in 2.7.3.3 of this Section may be omitted provided non-destructive tests by ultrasonic or radiographic methods are carried out on the entire circumference of all butt welds with satisfactory results.
2.7.3.5 Pneumatic leak testing may be carried out on water sensitive systems, in lieu of hydrostatic testing. In certain circumstances, a combined hydrostatic – pneumatic strength test may also be applied, where the system is partially filled with water and the free space above is pressurized with a test gas (typically air or nitrogen). When pneumatic tests cannot be avoided, the sufficient safety precautions are to be taken.

Section 8 ARRANGEMENT

2.8.1 Piping arrangement

2.8.1.1 All pipes are to be properly secured, and provision is to be made to avoid excessive stresses caused by thermal expansion in pipes or due to deflection of ship structure.
2.8.1.2 Penetration pieces or steel pads are to be provided for pipes passing through watertight or gastight structures. If pipes are fixed on watertight bulkhead by bolts, bolt holes are not to pass through bulkhead.
For pipes pass through deck or bulkhead with fire division, their arrangement is not to damage fire division of deck or bulkhead.
2.8.1.3 The pipe piercing the collision bulkhead below the freeboard deck (bulkhead deck for passenger ships) is to be fitted with a remotely controlled valve capable of being operated from above the freeboard deck (bulkhead deck for passenger ships). The valve is to be normally closed. If the remote control system should fail during operation of the valve, the valve is to close automatically or be capable of being closed manually from a position above the freeboard deck (bulkhead deck for passenger ships).
The above-mentioned valves are to be fitted on the forward or after side of the collision bulkhead provided that the space in which they are located is not a cargo space.

All valves are to be of steel, bronze or other approved ductile material. Valves of ordinary cast iron or similar material are not acceptable.
2.8.1.4 The collision bulkhead may be pierced below the bulkhead deck by not more than one pipe for dealing with fluid in the forepeak tank. If the forepeak is divided to hold two different kinds of liquids, the collision bulkhead of each compartment may be allowed to be pierced below the bulkhead deck for passenger ships by one pipe.
2.8.1.5 For ships required for damage stability, the arrangement is to ensure that the continuing flooding will not extend to the compartments other than those with assumption of flooding , provided the piping system is fitted in the assumed flooding compartments.
2.8.1.6 Fresh water pipes are not to be led through oil tanks, nor oil pipes through fresh water tanks. Where it is impracticable to do so, the pipes are to be led inside an oil-tight pipe tunnel.

2.8.2 Separation of tanks
2.8.2.1 Where the following tanks are adjacent to each other, they are to be separated by cofferdams:
(1) lubricating oil tanks and fresh water tanks;
(2) boiler feed water tanks and fuel oil tanks;
(3) fresh water tanks and fuel oil tanks;
(4) boiler feed water tanks and lubricating oil tanks.
2.8.2.2 Where the fuel oil tank is directly adjacent to lubricating oil tank, the welding of the adjacent bulkhead is to be of full penetration type.

2.8.3 Corrosion protection
2.8.3.1 Steel pipes are to be protected against corrosion, and protective coatings are to be applied on completion of all fabrication, i.e. bending, forming and welding of the steel pipes.

2.8.4 Fire protection
2.8.4.1 Air, overflow and sounding pipes for fuel oil tanks are not to be led through living quarters. Where this is not practicable, no detachable pipe joint is permissible in these spaces.
2.8.4.2 All steam, oil and water pipes as well as oil and other liquid tanks are not to be placed above or behind the switchboard. If this is not practicable, suitable protective means are to be provided.
In addition, oil pipes and oil tanks are not to be directly placed above the boilers, uptakes, steam pipes, exhaust gas pipes and silencers. If this is impracticable, effective means are to be made to prevent oil dropping onto the hot surfaces of the above-mentioned pipes or equipment.

2.8.5 Protection
2.8.5.1 Seawater pipes in cargo holds for dry cargoes, including cargo spaces of container ships, ro-ro ships, are to be protected from impact of cargo where they are liable to be damaged.
2.8.5.2 All pipes, fittings, pumps, filters and other equipment of piping systems are to be provided with drain valves or cocks where necessary.
2.8.5.3 The pipes which may be subject to a pressure greater than the design value are to be fitted with relief valves at the delivery side of pumps. The discharge from relief valves fitted in oil pipelines is to be led to the suction side of pumps or tanks. Heaters and air compressor coolers are also to be fitted with relief valves. The releasing pressure of relief valves is, in general, not to be greater than the design pressure of pipelines.
2.8.5.4 Where pressure-reducing valves are fitted in the pressure piping, a relief valve and a pressure gauge are to be fitted behind the pressure-reducing valve and a by-pass pipe fitted with a screw-down valve is to be provided. Or, at least an additional spare pressure reducing valve for replacement at any time is to be provided. The provision of pressure-reducing valves in the gas supply piping of the control system and relevant requirements are given in 2.2.2.2, PART SEVEN of the Rules.

2.8.6 Insulation
2.8.6.1 The insulation lagged on the machinery surfaces with a temperature over 220℃ is to comply with the provisions in 1.3.6.3 of this PART. The insulation in way of dismountable joints and valves is to be easily renewed.
2.8.6.2 Pipes passing through refrigerated spaces (including fish rooms), excluding those intended to serve such spaces, are to be well insulated to prevent freezing and from the steel structure.
2.8.6.3 Where the pipes pass through chambers intended for temperatures of 0℃ or below, they are in general to be insulated from the steel structure of these chambers.

2.8.7 Compensation for expansion

2.8.7.1 Suitable provision for compensation is to be made for all pipes subject to expansion, contraction or other strain, such as bends, loops, or expansion joints as required.
2.8.7.2 The adjoining pipes are to be suitably aligned and anchored. Where necessary, expansion pieces of bellows type are to be protected against mechanical damage.
2.8.7.3 In general, slip type expansion joints are only used for pipes in spaces accessible to operators for inspection during normal navigation. Slip type expansion joints are not to be used for pipes in spaces such as dry cargo tank and deep tank which are not easy to inspect. Slip type expansion joints may be used for pipes in tanks carrying the same liquid as that in the pipes.
Slip type expansion joints are not to be used in the systems listed below:
(1) class I Piping system;
(2) oil (such as fuel oil, lubricating oil, hydraulic oil, thermal oil) pipes of Class II piping system;
(3) steering gear hydraulic system;
(4) starting air and control air system;
(5) boiler feed water system;
(6) fixed gas fire extinguishing system;
(7) bilge pipelines located in cargo hold, deep tanks and double bottom tanks;
(8) cargo oil lines located in pipe duct keels;
(9) oil pipes, such as fuel oil, lubricating oil, hydraulic oil and thermal oil, of Class III systems located in machinery spaces of category A, accommodation spaces or non-mechanically ventilated pipe duct keels;
(10) pipes passing through other tanks;
(11) exhaust system.
For detailed requirements to slip type expansion joints, see relevant provisions in 2.5.3 of Section 5 and Appendix 3 of this Chapter.

2.8.8 Installation of valves and fittings

2.8.8.1 Valves, cocks, pipes or other fittings attached direct to the plating of tanks, and to bulkheads, flats or tunnels which are required to be of watertight construction, are to be secured by means of studs screwed into but not penetrating through the pads welded on the plating. Alternatively, the studs or the bulkhead piece may be welded to the plating.
2.8.8.2 The valves and fittings fitted in engine rooms, boiler rooms, pump rooms and shaft tunnels are to be easily accessible for operation. Where the valves and fittings are situated under the floor plate not easily accessible for operation, they are to be provided with extended operating rods or tools for operation. Furthermore, holes are to be cut in the floor plate under which the valves or fittings are located and to be provided with covers.
2.8.8.3 Where relief valves are fitted in sea water systems, these valves are to be fitted in readily visible positions above the platform. The arrangements are to be such that any discharge from the relief valves will also be readily visible.
2.8.8.4 All valves which are provided with remote control are to be arranged for local manual operation, independent of the remote operating mechanism. Opening and/or closing of the valves by local manual means is not to render the remote control system inoperable.
Sea valves, ship-side valves and valves on collision bulkhead are to be permanently arranged for local manual operation.

2.8.9 Installation of ship-side valves and fittings (other than those on scuppers and sanitary discharges)

2.8.9.1 All sea inlet and overboard discharge pipes are to be fitted with valves or cocks secured direct to the shell plating, or to the plating of fabricated steel sea chests attached to the shell plating. The installation of the valves or cocks is to comply with the following requirements in (1) or (2):
(1) The valves or cocks are to be secured by means of studs screwed into but not penetrating through the pads welded on the shell plating or sea chests.
(2) The valves or cocks may be secured to the distance piece welded on the shell plating or sea chests. The wall thickness of the distance piece is to comply with the requirements in Table 5.3.4.2 of this PART, or may be same as that of the shell plating in way of its penetration into the distance piece. The distance piece is to be adequately strengthened as to ensure its rigidity.
2.8.9.2 All suction and discharge valves and cocks secured direct to the shell plating of the ship are to be fitted with spigots passing through the plating, but the spigots on the valves or cocks may be omitted if these fittings are attached to pads or distance pieces which themselves form spigots in way of the shell plating. Blow-off valves or cocks are also to be fitted with a protection ring through which the spigot is to pass, the ring being on the outside of the shell plating.

2.8.9.3 Blow-off valves or cocks on the ship's side are to be fitted in accessible positions above the level of the working platform, and are to be provided with indicators showing whether they are open or shut.
2.8.9.4 It is to be avoided to locate the overboard discharges in way of the areas where the lifeboats and accommodation ladders are lowered. Where this is not practicable, suitable means are to be provided to prevent any discharge of water into the lifeboats or onto the accommodation ladders.
2.8.9.5 Sea inlet and overboard discharge valves and cocks are in all cases to be fitted in easily accessible positions and, so far as practicable, are to be readily visible. Indicators are to be provided local to the valves and cocks, showing whether they are open or shut. The operating position of hand wheel or manual operating device of main sea inlet valve is to be situated not less than 450 mm above the lower platform.
If an inlet or outlet pipeline passes through wing tank, the above-mentioned ship-side valve may be installed on inner bulkhead of wing tank. The wall thickness of pipes between inner bulkhead and shell plate of wing tank is to comply with the requirements in Table 5.3.4.2 of this PART, or may be same as that of the shell plating in way of its penetration into the pipes.
2.8.9.6 Gratings are to be fitted at all openings in the ship's side for sea inlet valves and sea chests. The direction of grating bars is to be in line with the length of the ship. The net area through the gratings is not to be less than twice that of the valves connected to the sea inlets, and provision is to be made for clearing the gratings by use of low pressure steam or compressed air.
2.8.9.7 Ship-side valves and fittings as well as sea chests, if made of steel, are to be suitably protected against wastage.
2.8.9.8 Sea chests are to be so arranged as to avoid the formation of air pocket. Where a vent pipe is fitted on the top of the sea chest, a screw-down valve is to be fitted at the root of the vent pipe. The open end of the vent pipe is to be extended to a position above the bulkhead deck or to be led overboard in the vicinity of the bulkhead deck and a ship-side screw-down valve is to be fitted.
2.8.9.9 For sea connections for ships having ice notations, see relevant provisions specified in Chapter 14 of this PART.

Appendix 1 PRODUCTION AND APPLICATION OF PLASTIC PIPING SYSTEMS ON SHIPS①

1.1 Terms and Definitions of this Appendix

1.1.1 "Plastic(s)" means both thermoplastic and thermosetting plastic materials with or without reinforcement, such as PVC and fiber reinforced plastics − FRP. Plastic(s) includes synthetic rubber and materials of similar thermos/mechanical properties.

1.1.2 "Pipes/piping systems" means those made of plastics and include the pipes, fittings, system joints, method of joining and any internal or external liners, coverings and coatings required to comply with the performance criteria.

1.1.3 "Joint" means the location at which two pieces of pipe or a pipe and a fitting are connected together. The joint may be made by adhesive bonding, laminating, welding, flanges and mechanical joints listed in Table 2.5.3.1(1), Chapter 2 of this PART.

1.1.4 "Fittings" means bends, elbows, fabricated branch pieces etc. of plastic materials.

1.1.5 "Nominal pressure" means the maximum permissible working pressure which should be determined in accordance with the requirements in 1.3.1 of this Appendix.

1.1.6 "Design pressure" means the maximum working pressure which is expected under operation conditions or the highest set pressure of any safety valve or pressure relief device on the system, if fitted.

1.1.7 "Fire endurance" means the capability of piping to maintain its strength and integrity (i.e. capable of performing its intended function) for some predetermined period of time while exposed to fire.

1.1.8 "Essential to the safety of ship" means all piping systems that in event of failure will pose a threat to personnel and the ship (piping systems essential to the safety are provided by Table 1.4.1).

1.1.9 "Essential services" are those services essential for propulsion and steering and safety of the ship as specified in 1.1.2, Chapter 1, PART FOUR of the Rules.

1.2 Scope

1.2.1 This Appendix is applicable to piping systems on ships, including pipe joints and fittings, made predominately of other material than metal.

1.2.2 The use of mechanical joints approved for the use in metallic piping systems only are not applicable in this Appendix.

1.2.3 Piping systems intended for non-essential services are to meet only the requirements of recognized standards and 1.3.1(3)②, 1.4.2, 1.5.2~1.5.7 and 1.6 of this Appendix.

1.3 General Requirements

The specification of piping is to be in accordance with a recognized national or international standard acceptable to CCS. In addition, the following requirements apply:

1.3.1 Strength

(1) The strength of the pipes is to be determined by a hydrostatic test failure pressure of a pipe specimen under the standard conditions: atmospheric pressure equal to 0.1 MPa, relative humidity 30%, environmental and carried fluid temperature 298 K (25℃).

(2) The strength of fittings and joints is not to be less than that of the pipes.

(3) The nominal pressure is to be determined from the following conditions:

① Internal Pressure

For an internal pressure, the following is to be taken whichever is smaller:

$$Pn \text{ int } \frac{c}{\lambda} Psth/4 \quad \text{or} \quad Pn \text{ int } \frac{c}{\lambda} Plth/2.5$$

where: Psth — short-term hydrostatic test pipe failure pressure, in MPa;

Plth — long-term hydrostatic test pipe failure pressure (> 100,000 h), in MPa.

② External Pressure(for any installation which may be subject to vacuum conditions inside the pipe or a head of liquid acting on the outside of the pipe; and for any pipe installation required to remain operational in case of flooding damage, as per SOLAS II-1/8-1, or for any pipes that would allow progressive flooding to other compartments through damaged piping or through open ended pipes in the compartments)

For an external pressure:

---

① It is addressed by IACS according to the provisions of IMO resolution A.753(18), as amended by IMO Res. MSC.313(88) and IMO Res. MSC. 399(95).

$$P_{n\,ext} \le P_{col}/3$$

where: Pcol — pipe collapse pressure, in MPa.

In no case is the pipe collapse pressure to be less than 0.3 MPa.

The maximum working external pressure is a sum of the vacuum inside the pipe and a head of liquid acting on the outside of the pipe.

(4) Notwithstanding the requirements of (3)① or (3)② above as applicable, the pipe or pipe layer minimum wall thickness is to follow recognized standards. In the absence of standards for pipes not subject to external pressure, the requirements of (3)② above are to be met.

(5) The maximum permissible working pressure is to be specified with due regard for maximum possible working temperatures in accordance with manufacturer's recommendations.

1.3.2 Axial Strength

(1) The sum of the longitudinal stresses due to pressure, weight and other loads is not to exceed the allowable stress in the longitudinal direction.

(2) In the case of fiber reinforced plastic pipes, the sum of the longitudinal stresses is not to exceed half of the nominal circumferential stress derived from the nominal internal pressure condition (see 1.3.1 of this Appendix).

1.3.3 Impact Resistance

(1) Plastic pipes and joints are to have a minimum resistance to impact in accordance with recognized national or international standards.

(2) After testing, the specimen is to be tested to a hydraulic pressure equal to 2.5 times the design pressure for at least 1 h.

1.3.4 Temperature

(1) The permissible working temperature depending on the working pressure is to be in accordance with manufacturer's recommendations, but in each case it is to be at least 20℃ lower than the minimum heat distortion/deflection temperature of the pipe material, determined according to ISO 75-2 method A, or equivalent, e.g. ASTMD648-18.

(2) The minimum heat distortion/deflection temperature is not to be less than 80℃.

1.4 Requirements for Pipes/Piping Systems Depending on Service and/or Locations

1.4.1 Fire Endurance

(1) Pipes and their associated joints and fittings whose integrity is essential to the safety of ships, including plastic piping required by SOLAS II-2/21.4 to remain operational after a fire casualty, are required to meet the minimum fire endurance requirements of Appendix 1 or 2, as applicable, of IMO resolution A.753 (18) , as amended by IMO Res. MSC. 313(88) and IMO Res. MSC. 399(95).

(2) Unless instructed otherwise by the Administration, fire endurance tests are to be carried out with specimen representative for pipes, joints and fittings[①]:

① Pipes:

- for sizes with outer diameter < 200 mm the minimum outer diameter and wall thickness[②]
- for sizes with outer diameter ≥ 200 mm one test specimen for each category of t/d (D = outer diameter, t = structural wall thickness). A scattering of ±10% for t/D is regarded as the same group. Minimum size approved is equal to the diameter of specimen successfully tested.

② Joints

- Each type of joint applicable for applied fire endurance level tested on pipe to pipe specimen.

(3) Means are to be provided to ensure a constant media pressure inside the test specimen during the fire test as specified in Appendix 1 or 2 of the IMO Res.A.753(18), as amended by IMO Resolutions MSC.313(88) and MSC.399(95). During the test it is not permitted to replace media drained by fresh water or nitrogen.

(4) Depending on the capability of a piping system to maintain its strength and integrity, there exist five different levels of fire endurance for piping systems.

① Level 1: Piping having passed the fire endurance test specified in Appendix 1 of IMO resolution A.753(18) , as amended by IMO Res. MSC. 313(88) and IMO Res. MSC. 399(95) for duration of

---

① A test specimen incorporating several components of a piping system may be tested in a single test.

② Test conditions are most demanding for minimum wall thickness and thus larger wall thickness is covered. A key factor determining the fire performance of a pipe component variant is the thickness-to-diameter (t/D) ratio and whether it is larger or smaller than that of the variant which has been fire-tested. If fire-protective coatings or layers are included in the variant used in the fire test, only variants with the same or greater thickness of protection, regardless of the (t/D) ratio, are to be qualified by the fire test.

a minimum of one hour without loss of integrity in the dry condition is considered to meet level 1 fire endurance standard (L1).

② Level 1W: Piping systems similar to level 1 systems except these systems do not carry flammable fluid or any gas and a maximum 5% flow loss in the system after exposure is acceptable①, which is considered to meet level 1W fire endurance standard (L1W).

③ Level 2: Piping having passed the fire endurance test specified in Appendix 1 of IMO resolution A.753(18) , as amended by IMO Res. MSC. 313(88) and IMO Res. MSC. 399(95) for a duration of a minimum of 30 min in the dry condition is considered to meet level 2 fire endurance standard (L2).

④ Level 2W: Piping systems similar to level 2 systems except a maximum 5% flow loss in the system after exposure is acceptable①, which is considered to meet level 2W fire endurance standard (L2W).

⑤ Level 3: Piping having passed the fire endurance test specified in Appendix 2 of IMO resolution A.753(18), as amended by IMO Res. MSC. 313(88) and IMO Res. MSC. 399(95) for a duration of a minimum of 30 min in the wet condition is considered to meet level 3 fire endurance standard (L3).

(5) Permitted use of piping depending on fire endurance, location and piping system is given in Table 1.4.1.

(6) For Safe Return to Port purposes (SOLAS II-2/21.4), plastic piping can be considered to remain operational after a fire casualty if the plastic pipes and fittings have been tested to L1 standard.

1.4.2 Flame Spread

(1) All pipes, except those fitted on open decks and within tanks, cofferdams, pipe tunnels and ducts, if separated from accommodation, permanent manned areas and escape ways by means of an A class bulkhead, are to have low surface flame spread characteristics not exceeding average values listed in Appendix 3 of IMO resolution A.753(18), as amended by IMO Res. MSC. 313(88) and IMO Res. MSC. 399(95).

(2) Surface flame spread characteristics are to be determined using the procedure given in the 2010 FTP Code, Annex 1, Part 5 with regard to the modifications due to the curvilinear pipe surfaces as listed in Appendix 3 of IMO Resolution A.753(18), as amended by IMO Res. MSC. 313(88) and IMO Res. MSC. 399(95).

(3) Surface flame spread characteristics may also be determined using the test procedures given in ASTM D635, or in other national equivalent standards. Under the procedure of ASTM D635 a maximum burning rate of 60 mm/min applies. In case of adoption of other national equivalent standards, the relevant acceptance criteria are to be defined.

1.4.3 Fire Protection Coatings

Where a fire protective coating of pipes and fittings is necessary for achieving the fire endurance level required, it is to meet the following requirements:

① The pipes are generally to be delivered from the manufacturer with the protective coating on.

② The fire protection properties of the coating are not to be diminished when exposed to salt water, oil or bilge slops. It is to be demonstrated that the coating is resistant to products likely to come into contact with the piping.

③ In considering fire protection coatings, such characteristics as thermal expansion, resistance against vibrations, and elasticity are to be taken into account.

④ The fire protection coatings are to have sufficient resistance to impact to retain their integrity.

1.4.4 Electrical Conductivity

Where electrical conductivity is to be ensured, the resistance of the pipes and fittings is not to exceed 1×10^5 Ω/m.

① The flow loss must be taken into account when dimensioning the system.

Notes:

L1—Fire endurance test (Annex 1 of IMO resolution A.753(18) , as amended by IMO Res. MSC. 313(88) and IMO Res. MSC. 399(95)) in dry conditions, 60 min;

L2—Fire endurance test (Annex 1 of IMO resolution A.753(18) , as amended by IMO Res. MSC. 313(88) and IMO Res. MSC. 399(95)) in dry conditions, 30 min;

L3—Fire endurance test (Annex 2 of IMO resolution A.753(18) , as amended by IMO Res. MSC. 313(88) and IMO Res. MSC. 399(95)) in wet conditions, 30 min;

L1W—Fire endurance test (see 1.4.1(2) of this Appendix);

L2W—Fire endurance test(see 1.4.1(2) of this Appendix);

O — No fire endurance test required;

NA—Not applicable;

× — Metallic materials having a melting point greater than 925℃.

① Where non-metallic piping is used, remotely controlled valves to be provided at ship's side (valve is to be controlled from outside space).

② Remote closing valves to be provided at the cargo tanks.

③ When cargo tanks contain flammable liquids with f.p. > 60 ℃, "O" may replace "NA" or "×".

④ For drains serving only the space concerned, "O" may replace "L1W".

⑤ When controlling functions are not required in statutory requirements or guidelines, "O" may replace "L1".

⑥ For pipe between machinery space and deck water seal, "O" may replace "L1".

⑦ For passenger vessels, "×" is to replace "L1".

⑧ Scuppers serving open decks in positions 1 and 2, as defined in regulation 13 of the Protocol of 1988 relating to the International Convention on Load Lines, 1966, should be "×" throughout unless fitted at the upper end with the means of closing capable of being operated from a position above the freeboard deck in order to prevent down-flooding.

⑨ For essential services, such as fuel oil tank heating and ship's whistle, "×" is to replace "O".

⑩ For tankers where compliance with paragraph 3.6, regulation 19 of Annex I of MARPOL is required, "NA" is to replace "O".

⑪ L3 in service spaces, NA in accommodation and control spaces.

⑫ Type Approved plastic piping without fire endurance test (0) is acceptable downstream of the tank valve, provided this valve is metal seated and arranged as fail-to-closed or with quick closing from a safe position outside the space in the event of fire.

⑬ For Passenger Ships subject to SOLAS II-2, Reg.21.4 (Safe return to Port), plastic pipes for services required to remain operative in the part of the ship not affected by the casualty thresholds, such as systems intended to support safe areas, are to be considered essential services. In accordance with MSC Circular MSC.1/Circ.1369, interpretation 12, for Safe Return to Port purposes, plastic piping can be considered to remain operational after a fire casualty if the plastic pipes and fittings have been tested to L1 standard.

Location Definition:

A —Machinery spaces of category A: Machinery spaces of category A as defined in SOLAS① II-2/3.31.

B—Other machinery spaces: Spaces, other than category A machinery spaces and cargo pump rooms, containing propulsion machinery, boilers, fuel oil units, steam and internal combustion engines, generators and major electrical machinery, pumps, oil filling stations, refrigerating, stabilizing, ventilation and air-conditioning machinery, and similar spaces, and trunks to such spaces.

C—Cargo pump rooms: Spaces containing cargo pumps and entrances and trunks to such spaces.

D—Ro-ro cargo holds: Ro-ro cargo holds are ro-ro cargo spaces and special category spaces as defined in SOLAS① regulation II-2/3.41 and 3.46.

E—Other dry cargo holds: All spaces other than ro-ro cargo holds used for non-liquid cargo and trunks to such spaces.

F—Cargo tanks: All spaces used for liquid cargo and trunks to such spaces.

G—Fuel oil tanks: All spaces used for fuel oil (excluding cargo tanks) and trunks to such spaces.

H—Ballast water tanks: All spaces used for ballast water and trunks to such spaces.

I— Cofferdams, voids, etc.: Cofferdams and voids are those empty spaces between two bulkheads separating two adjacent compartments.

J—Accommodation and service spaces: Accommodation spaces, service spaces and control stations as defined in SOLAS①

① SOLAS Chapter II-2.

regulation II-2/3.1, 3.45, 3.18.
K—Open decks: Open deck spaces as defined in SOLAS① regulation II-2/9.2.2.3.2(5).

1.5 Material Approval and Quality Control During Manufacture

1.5.1 Except as required in 1.2.3 of this Appendix, Prototypes of pipes and fittings are to be tested to determine short-term and long-term design strength, fire endurance and low surface flame spread characteristics (if applicable), electrical resistance (for electrically conductive pipes), impact resistance in accordance with this Appendix.

1.5.2 For prototype testing, representative samples of pipes and fittings are to be selected to the satisfaction of CCS.

1.5.3 The manufacturer is to have quality system that meets ISO 9000 series standards or equivalent.

The quality system is to consist of elements necessary to ensure that pipes and fittings are produced with consistent and uniform mechanical and physical properties.

1.5.4 Each pipe and fitting is to be tested by the manufacturer at a hydrostatic pressure not less than 1.5 times the nominal pressure. Alternatively, for pipes and fittings not employing hand lay-up techniques, the hydrostatic pressure test may be carried out in accordance with the hydrostatic testing requirements stipulated in the recognized national or international standard accepted by CCS to which the pipe or fittings are manufactured, provided that there is an effective quality system in place.

1.5.5 Pipes and fittings are to be permanently marked with identification. Identification is to include pressure ratings, the design standards that the pipe or fitting is manufactured in accordance with, and the material of which the pipe or fitting is made.

1.5.6 In case the manufacturer does not have an approved quality system complying with ISO 9000 series or equivalent, pipes and fittings are to be tested in accordance with this Appendix to the satisfaction of the Surveyors for every batch of pipes.

1.5.7 Depending upon the intended application, CCS may require the pressure testing of each pipe and/or fitting.

1.6 Installation

1.6.1 Supports

(1) Selection and spacing of pipe supports in shipboard systems are to be determined as a function of allowable stresses and maximum deflection criteria. Support spacing is not to be greater than the pipe manufacturer's recommended spacing. The selection and spacing of pipe supports are to take into account pipe dimensions, pipe length, mechanical and physical properties of the pipe material, mass of pipe and contained fluid, external pressure, operating temperature, thermal expansion effects, loads due to external forces, thrust forces, water hammer, vibrations, maximum accelerations to which the system may be subjected. Combination of loads is to be considered.

(2) Each support is to evenly distribute the load of the pipe and its contents over the full width of the support. Measures are to be taken to minimize wear of the pipes where they contact the supports.

(3) Heavy components in the piping system such as valves and expansion joints are to be independently supported.

1.6.2 Expansion

(1) Suitable provision is to be made in each pipeline to allow for relative movement between pipes made of plastic and the steel structure, having due regard to:

① the difference in the coefficients of thermal expansion;

② deformations of the ship's hull and its structure.

(2) When calculating the thermal expansions, account is to be taken of the system working temperature and the temperature at which assembly is performed.

1.6.3 External Loads

(1) When installing the piping, allowance is to be made for temporary point loads, where applicable. Such allowances are to include at least the force exerted by a load (person) of 100 kg at mid-span on any pipe of more than 100 mm nominal outside diameter.

(2) Besides for providing adequate robustness for all piping including open-ended piping a minimum wall thickness, complying with 1.3.1 of this Appendix, may be increased taking into account the conditions encountered during service on board ships.

(3) Pipes are to be protected from mechanical damage where necessary.

1.6.4 Strength of Connections

(1) The strength of connections is not to be less than that of the piping system in which they are installed.

(2) Pipes may be assembled using adhesive-bonded, welded, flanged or other joints.

(3) Adhesives, when used for joint assembly, are to be suitable for providing a permanent seal between the

pipes and fittings throughout the temperature and pressure range of the intended application.
(4) Tightening of joints is to be performed in accordance with manufacturer's instructions.

1.6.5 Installation of Conductive Pipes

(1) In piping systems for fluids with conductivity less than 1,000 pS/m, such as refined products and distillates use is to be made of conductive pipes.
(2) Regardless of the fluid being conveyed, plastic piping is to be electrically conductive if the piping passes through a hazardous area. The resistance to earth from any point in the piping system is not to exceed 1×10^6 Ω/m. It is preferred that pipes and fittings be homogeneously conductive. Pipes and fittings having conductive layers are to be protected against a possibility of spark damage to the pipe wall. Satisfactory earthing is to be provided.
(3) After completion of the installation, the resistance to earth is to be verified. Earthing wires are to be accessible for inspection.

1.6.6 Application of Fire Protection Coatings

(1) Fire protection coatings are to be applied on the joints, where necessary for meeting the required fire endurance as for 1.4.3 of this Appendix, after performing hydrostatic pressure tests of the piping system.
(2) The fire protection coatings are to be applied in accordance with manufacturer's recommendations, using a procedure approved in each particular case.

1.6.7 Penetration of Divisions

(1) Where plastic pipes pass through A or B class divisions, arrangements are to be made to ensure that the fire endurance is not impaired. These arrangements are to be tested in accordance with Recommendations for fire test procedures for A, B and F bulkheads 2010 FTP Code, annex 1, part 3 (Res. MSC.307(88) as amended by Res.MSC.437(99)).
(2) When plastic pipes pass through watertight bulkheads or decks, the watertight integrity of the bulkhead or deck is to be maintained. For pipes not able to satisfy the requirements in 1.3.1(3)② of this Appendix, a metallic shut-off valve operable from above the freeboard deck should be fitted at the bulkhead or deck.
(3) If the bulkhead or deck is also a fire division and destruction by fire of plastic pipes may cause the inflow of liquid from tanks, a metallic shut-off valve operable from above the freeboard deck should be fitted at the bulkhead or deck.

1.6.8 Control during Installation

(1) Installation is to be in accordance with the manufacturer's guidelines.
(2) Prior to commencing the work, joining techniques are to be approved.
(3) The tests and examinations specified in this Appendix are to be completed before shipboard piping installation commences.
(4) The personnel performing this work are to be properly qualified and certified to the satisfaction of CCS.
(5) The procedure of making bonds is to include:

① materials used;
② tools and fixtures;
③ joint preparation requirements;
④ cure temperature;
⑤ dimensional requirements and tolerances;
⑥ tests acceptance criteria upon completion of the assembly.

(6) Any change in the bonding procedure which will affect the physical and mechanical properties of the joint is to require the procedure to be re-qualified.

1.6.9 Bonding Procedure Quality Testing

(1) A test assembly is to be fabricated in accordance with the procedure to be qualified and it is to consist of at least one pipe-to-pipe joint and one pipe-to-fitting joint.
(2) When the test assembly has been cured, it is to be tested to a hydraulic pressure equal to 2.5 times the design pressure for at least 1 h. No leakage or separation of joints is allowed. The test is to be conducted so that the joint is loaded in both longitudinal and circumferential directions.
(3) Selection of the pipes used for test assembly, is to be in accordance with the following:

① When the largest size to be joined is 200 mm nominal outside diameter, or smaller, the test assembly is to be the largest piping size to be joined.
② When the largest size to be joined is greater than 200 mm nominal outside diameter, the size of the test assembly is to be either 200 mm or 25% of the largest piping size to be joined, whichever is greater.

(4) When conducting performance qualifications, each bonder and each bonding operator are to make up test assemblies, the size and number of which are to be as required above.

1.6.10 Testing after Installation on Board

(1) Piping systems for essential services are to be tested to a pressure equal to 1.5 times the design pressure or 0.4 MPa, whichever is greater. Notwithstanding the requirement above, the requirement in 1.6.10(2) may be applied to open ended pipes (drains, effluent, etc.).
(2) Piping systems for non-essential services are to be checked for leakage under operational conditions.
(3) For piping required to be electrically conductive, earthing is to be checked and random resistance testing is to be conducted.

1.7 Test specification for plastic pipes

1.7.1 General requirements

1.7 contains requirements for the type approval of plastic pipes. It is applicable to piping systems, including pipe joints and fittings, made predominately of other material than metal.

1.7.2 Documentation

The following information for the plastic pipes, fittings and joints is to be submitted for consideration and approval:

(1) General information:
- ① Pipe and fitting dimensions;
- ② Maximum internal and external working pressure;
- ③ Working temperature range;
- ④ Intended services and installation locations;
- ⑤ The level of fire endurance;
- ⑥ Electrically conductive;
- ⑦ Intended fluids;
- ⑧ Limits on flow rates;
- ⑨ Serviceable life;
- ⑩ Installation instructions;
- ⑪ Details of marking.

(2) Drawings and supporting documentation:
- ① Certificates and reports for relevant tests previously carried out;
- ② Details of relevant standards;
- ③ All relevant design drawings, catalogues, data sheets, calculations and functional descriptions;
- ④ Fully detailed sectional assembly drawings showing pipe, fittings and pipe connections.

(3) Materials(as applicable):
- ① The resin type;
- ② Catalyst and accelerator types, and concentration employed in the case of reinforced polyester resin pipes or hardeners where epoxide resins are employed;
- ③ A statement of all reinforcements employed where the reference number does not identify the mass per unit area or the tex number of a roving used in a filament winding process, these are to be detailed;
- ④ Full information regarding the type of gel-coat or thermoplastic liner employed during construction, as appropriate;
- ⑤ Cure / post-cure conditions. The cure and post-cure temperatures and times employ resin / reinforcement ratio;
- ⑥ Winding angle and orientation.
- ⑦ Joint bonding procedures and qualification tests results, see 1.6.8(5) of this Appendix.

1.7.3 Testing

Testing is to demonstrate compliance of the pipes, fittings and joints for which type approval is sought with the requirement of this Appendix.

Pipes, joints and fittings are to be tested for compliance with the requirements of standards① acceptable to CCS.

① For the list of standards refer to IACS Recommendation No.86.

Appendix 2 FLEXIBLE HOSES

1.1 Definition

1.1.1 Flexible hose assembly① means short length of metallic or non-metallic hose normally with prefabricated end fittings ready for installation.

Note: Flexible hose assemblies for essential services or containing either flammable or toxic media are not to exceed 1.5 m in length.

1.2 Scope

1.2.1 This Appendix applies to flexible hoses of metallic or non-metallic material intended for a permanent connection between a fixed piping system and items of machinery. This Appendix may also be applied to temporary connected flexible hoses or hoses of portable equipment.

1.2.2 Flexible hose assemblies satisfying the requirements of this Appendix may be accepted for use in oil fuel, lubricating, hydraulic and thermal oil systems, fresh water and sea water cooling systems, compressed air systems, bilge and ballast systems and Class III steam systems. Flexible hoses in high pressure fuel oil injection systems are not to be accepted.

1.2.3 This Appendix is not applicable to hoses intended to be used in fixed fire extinguishing systems.

1.3 Design and construction

1.3.1 Flexible hoses constructed of rubber materials and intended for use in bilge, ballast, compressed air, oil fuel, lubricating, hydraulic and thermal oil systems are to incorporate a single, double or more, closely woven integral wire braid or other suitable material reinforcement.

Flexible hoses of plastics materials for the same purposes, such as Teflon or Nylon, which are unable to be reinforced by incorporating closely woven integral wire braid are to have suitable material reinforcement as far as practicable.

Where rubber or plastics materials hoses are to be used in oil supply lines to burners, the hoses are to have external wire braid protection in addition to the reinforcement mentioned above. Flexible hoses for use in steam systems are to be of metallic construction.

1.3.2 Flexible hoses are to be complete with approved end fittings in accordance with manufacturer's specification. The end connections that do not have a flange are to comply with the requirements of 2.5.3 of this Chapter as applicable and each type of hose/fitting combination is to be subject to prototype testing to the same standard as that required by the hose with particular reference to pressure and impulse tests.

1.3.3 The use of hose clamps and similar types of end attachments is not acceptable for flexible hoses in piping systems for steam, flammable media, starting air systems or for sea water systems where failure may result in flooding.

In other piping systems, the use of hose clamps may be accepted where the working pressure is less than 0.5 MPa and provided there are double clamps at each end connection.

1.3.4 Flexible hose assemblies intended for installation in piping systems where pressure pulses and/or high levels of vibration are expected to occur in service, are to be designed for the maximum expected impulse peak pressure and forces due to vibration. The tests required by 1.5 of this Appendix are to take into consideration the maximum anticipated in-service pressures, vibration frequencies and forces due to installation.

1.3.5 The following flexible hose assemblies constructed of non-metallic materials are to be of fire-resistant type②, except in cases where such hoses are installed on open decks, as defined in SOLAS regulation II-2/9.2.3.3.2.2(10) as amended by IMO resolutions up to MSC.421(98) and not used for fuel oil lines:

(1) used for flammable media;

(2) used for sea water systems where failure may result in flooding.

1.3.6 Flexible hose assemblies are to be selected for the intended location and application taking into consideration ambient conditions, compatibility with fluids under working pressure and temperature conditions.

1.4 Installation

1.4.1 In general, flexible hoses are to be limited to a length necessary to provide for relative movement between fixed and flexibly mounted items of machinery/equipment or systems.

---

① Flexible hoses are to be designed and manufactured according to the recognized national or international standards.

② Fire resistance is to be demonstrated by testing to ISO 15540 and ISO 15541.

1.4.2 Flexible hose assemblies are not to be installed where they may be subjected to torsion deformation (twisting) under normal operating conditions.
1.4.3 The number of flexible hoses, in piping systems mentioned in 1.2.2 is to be kept to minimum and to be limited for the purpose stated in 1.2.1.
1.4.4 Where flexible hoses are intended to be used in piping systems conveying flammable fluids that are in close proximity of heated surfaces the risk of ignition due to failure of the hose assembly and subsequent release of fluids is to be mitigated as far as practicable by the use of screens or other similar protection.
1.4.5 Flexible hoses are to be installed in clearly visible and readily accessible locations.
1.4.6 The installation of flexible hose assemblies is to be in accordance with the manufacturer's instructions and use limitations with particular attention to the following:
(1) orientation;
(2) end connection support (where necessary);
(3) avoidance of hose contact that could cause rubbing and abrasion;
(4) minimum bend radii.

1.5 Tests
1.5.1 Acceptance of flexible hose assemblies is subject to satisfactory prototype testing. Prototype test programs for flexible hose assemblies are to be submitted for approval and are to be sufficiently detailed to demonstrate performance in accordance with the specified standards.
1.5.2 The tests are, as applicable, to be carried out on different nominal diameters of hose type complete with end fittings for pressure, burst, impulse resistance and fire resistance in accordance with the requirements of the relevant standard①.
Note:
Prototype tests are to be carried out for each size of hose assembly. However, for ranges with more than 3 different diameters, the prototype tests are to be carried out for at least:
(1) the smallest diameter,
(2) the largest diameter,
(3) Intermediate diameters selected based on the principle that prototype tests carried out
for a hose assembly with a diameter D are considered valid only for the diameters ranging between 0.5 D and 2 D.
For fire resistance tests the specimens shall be selected in accordance with ISO 15540.
1.5.3 All flexible hose assemblies are to be satisfactorily prototype burst tested to an international standard② to demonstrate they are able to withstand a pressure not less than four times its design pressure without indication of failure or leakage.

1.6 Marking
1.6.1 Flexible hoses are to be permanently marked with the following details:
(1) hose manufacturer's name or trademark;
(2) date of manufacture (month / year);
(3) designation type reference;
(4) nominal diameter;
(5) pressure rating;
(6) temperature rating.
Where a flexible hose assembly is made up of items from different manufacturers, the components are to be clearly identified and traceable to evidence of prototype testing.

---

① The following standards are to be used as applicable:
(1) ISO 6802 – Rubber and plastics hoses and hose assemblies with wire reinforcements – Hydraulic impulse test with flexing;
(2) ISO 6803 – Rubber or plastics hoses and hose assemblies with wire reinforcements 15 test without flexing;
(3) ISO 15540 – Ships and marine technology – Fire resistance of hose assemblies – Test methods;
(4) ISO 15541 – Ships and marine technology – Fire resistance of hose assemblies – Requirements for test bench;
(5) ISO 10380 – Pipework – Corrugated metal hoses and hose assemblies.

② The international standards, e.g. EN or SAE for burst testing of non-metallic hoses, require the pressure to be increased until burst without any holding period at 4 × MWP.

Appendix 3 TYPE APPROVAL OF MECHANICAL JOINTS

1.1 General

1.1.1 This Appendix describes the type testing condition for type approval of mechanical joints intended for use in marine piping systems. Conditions outlined in these requirements are to be fulfilled before Type Approval Certificates are issued.

Alternative testing in accordance with national or international standards may also be accepted.

1.2 Scope

1.2.1 This Appendix is applicable to mechanical joints defined in 2.5.3 of this Chapter, including compression couplings and slip-on joints of different types for marine use.

1.3 Documentation

1.3.1 Following documents and information are to be submitted by manufacturer for assessment and/or approval:

(1) product quality assurance system implemented;

(2) complete description of the product;

(3) typical sectional drawings with all dimensions necessary for evaluation of joint design;

(4) complete specification of materials used for all components of the assembly;

(5) proposed test procedure as required in 1.5 of this Appendix and corresponding test reports or other previous relevant tests;

(6) initial information:

① maximum design pressures (pressure and vacuum);

② maximum and minimum design temperatures;

③ conveyed media;

④ intended services;

⑤ maximum axial, lateral and angular deviation, allowed by manufacturer;

⑥ installation details.

1.4 Materials

1.4.1 The materials used for mechanical joints are to comply with the requirements of 2.5.3.3 of this Chapter.

1.4.2 The manufacturer has to submit evidence to substantiate that all components are adequately resistant to working the media at design pressure and temperature specified.

1.5 Testing, procedures and requirements

The aim of tests is to demonstrate ability of the pipe joints to operate satisfactory under intended service conditions. The scope and type of tests to be conducted (e.g. applicable tests), sequence of testing, and the number of specimen, is subject to approval and will depend on joint design and its intended service in accordance with the requirements of this Appendix.

Unless otherwise specified, the water or oil as test fluid is to be used.

1.5.1 Test program

Testing requirements for mechanical joints are to be as indicated in Table 1.5.1.

1.5.2 Selection of test specimen

Test specimens are to be selected from production line or at random from stock.

Where there is a variety of size of joints requiring approval, a minimum of three separate sizes, representative of the range, from each type of joint to be tested in accordance with Table 1.5.1 are to be selected.

1.5.3 Mechanical Joint Assembly

Assembly of mechanical joints should consist of components selected in accordance with 1.5.2 and the pipe sizes appropriate to the design of the joints.

Where pipe material would affect the performance of mechanical joints, the selection of joints for testing is to take the pipe material into consideration.

Where not specified, the length of pipes to be connected by means of the joint to be tested is to be at least five times the pipe diameter. Before assembling the joint, conformity of components to the design requirements, is to be verified. In all cases the assembly of the joint is to be carried out only according to he manufacturer’s instructions. No adjustment operations on the joint assembly, other than that specified by

the manufacturer, are permitted during the test.

Test Procedures of Mechanical Joints **Table 1.5.1**

Tests		Types of Mechanical Joints			Notes and references
		Compression couplings and pipes unions	Slip-on joints		
			Grip type & slip type machined grooved type	Slip type	
1	Tightness test	×	×	×	1.5.5(1)
2	Vibration (fatigue) test	×	×	–	1.5.5(2)
3	Pressure pulsation test①	×	×	–	1.5.5(3)
4	Burst pressure test	×	×	×	1.5.5(4)
5	Pull-out test	×	×	–	1.5.5(5)
6	Fire endurance test	×	×	×	1.5.5(6), if required by 2.5.3.7 of this Chapter
7	Vacuum test	×③	×	×	1.5.5(7), for suction lines only
8	Repeated assembly test	×②	×	–	1.5.5(8)

Abbreviations: × test is required
– test is not required

Notes:

① For use in all Class I and II systems and those Class III systems where pressure pulsation other than water hammer is expected.

② Except permanent joint type (e.g., press and swage type).

③ Except joints with metal-to-metal tightening surface.

1.5.4 Test results acceptance criteria

Where a mechanical joint assembly does not pass all or any part of the tests in Table 1.5.1, two assemblies of the same size and type that failed are to be tested and only those tests which mechanical joint assembly failed in the first instance, are to be repeated. In the event where one of the assemblies fails the second test, that size and type of assembly is to be considered unacceptable.

The methods and results of each test are to be recorded and reproduced as and when required.

1.5.5 Methods of tests

(1) Tightness test

In order to ensure correct assembly and tightness of the joints, all mechanical joints are to be subject to a tightness test, as follows:

① Mechanical joint assembly test specimen is to be connected to the pipe or tubing in accordance with the requirements of 1.5.3 and the manufacturer's instructions, filled with test fluid and de-aerated.
Mechanical joints assemblies intended for use in rigid connections of pipe lengths, are not to be longitudinally restrained.
Pressure inside the joint assembly is to be slowly increased to 1.5 times of design pressure. This test pressure is to be retained for a minimum period of 5 min.
In the event where there is a drop in pressure or there is visual indication of leakage, the test (including fire test) is to be repeated for two test pieces. Where one test piece fails in the repeat test, the coupling will be regarded as having failed.
Other alternative tightness test procedure, such as pneumatic test, may be accepted.

② For compression couplings, a static gas pressure test is to be carried out to demonstrate the integrity of the mechanical joints assembly for tightness under the influence of gaseous media. The pressure is to be raised to maximum pressure or 7.0 MPa, whichever is less.

③ Where the tightness test is carried out using gaseous media as permitted in ① above, then the static pressure test mentioned in ② above need not be carried out.

(2) Vibration (fatigue) test

In order to establish the capability of the mechanical joint assembly to withstand fatigue, which is likely to occur due to vibrations under service conditions, mechanical joints assembly is to be subject to the following vibration test.

Conclusions of the vibration tests should show no leakage or damage.

① Testing of compression couplings and pipe unions
Compression couplings and pipe unions intended for use in rigid pipe connections are to be tested in accordance with this method described as follows.
Rigid connections are joints, connecting pipe length without free angular or axial movement.
Two lengths of pipe is to be connected by means of the joint to be tested. One end of the pipe is to be rigidly fixed while the other end is to be fitted to the vibration rig. The test rig and the joint

assembly specimen being tested is to be arranged as shown in Figure 1.

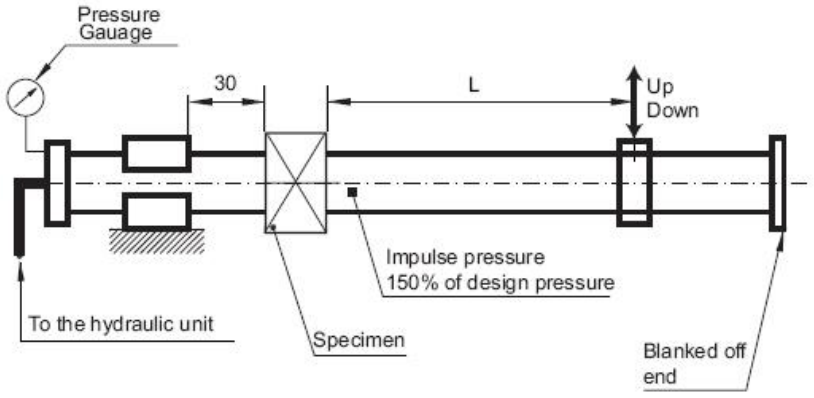

Figure 1

The assembly is to be filled with test fluid, de-aerated and pressurized to the design pressure of the joint.

Pressure during the test is to be monitored. In the event of drop in the pressure and visible leakage, the test is to be repeated as described in 1.5.4 of this Appendix.

Visual examination of the joint assembly is to be carried out.

Re-tightening may be accepted once during the first 1,000 cycles.

Vibration amplitude is to be within 5% of the value calculated from the following formula:

$$A = \frac{2SL^2}{3ED}$$

where: A – single amplitude, in mm;
L – length of the pipe, in mm;
S – allowable bending stress in N/mm^2 based on 0.25 of the yield stress;
E – modulus of elasticity of tube material (for mild steel, E = 210 kN/mm^2);
D – outside diameter of tube, in mm.

Test specimen is to withstand not less than 10^7 cycles with frequency 20 to 50 Hz without leakage or damage.

② Grip type and machine grooved type joints

Grip type joints and other similar joints containing elastic elements are to be tested in accordance with the following method.

A test rig of cantilever type used for testing fatigue strength of components may be used. The test specimen being tested is to be arranged in the test rig as shown in Figure 2.

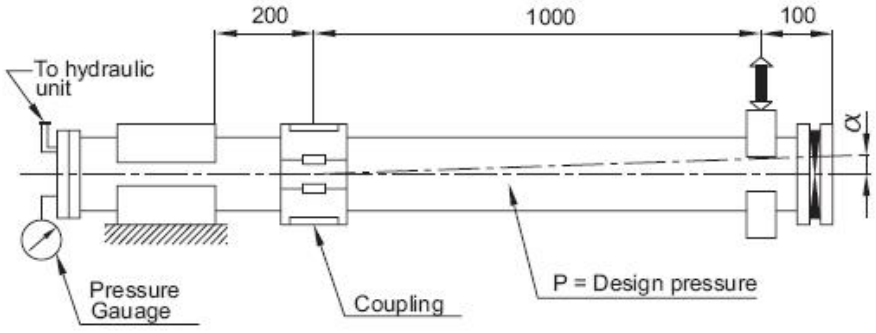

Figure 2

Two lengths of pipes are to be connected by means of joint assembly specimen to be tested. One end of the pipe is to be rigidly fixed while the other end is to be fitted to the vibrating element on the rig.

The length of pipe connected to the fixed end should be kept as short as possible and in no case exceeds 200 mm.

Mechanical joint assemblies are not to be longitudinally restrained.

The assembly is to be filled with test fluid, de-aerated and pressurized to the design pressure of the joint. Preliminary angle of deflection of pipe axis is to be equal to the maximum angle of deflection, recommended by the manufacturer. The amplitude is to be measured at 1 m distance from the center line of the joint assembly at free pipe end connected to the rotating element of the rig (see Figure 2). Parameters of testing are to be as indicated in the table below and to be carried out on the same assembly:

Number of cycles	Amplitude, in mm	Frequency, in Hz
3×10^6	± 0.06	100
3×10^6	± 0.5	45
3×10^6	± 1.5	10

Pressure during the test is to be monitored. In the event of a drop in the pressure or visible leakage, the test is to be repeated as described in 1.5.4 of this Appendix.

Visual examination of the joint assembly is to be carried out.

(3) Pressure pulsation test

In order to determine capability of mechanical joint assembly to withstand pressure pulsation likely to occur during working conditions, joint assemblies intended for use in rigid connections of pipe lengths, are to be tested in accordance with the following method.

The mechanical joint test specimen for carrying out this test may be the same as that used in the test in 1.5.5(1) provided it passed that test.

The vibration test in 1.5.5(2) and the pressure pulsation test are to be carried out simultaneously for compression couplings and pipe unions.

The mechanical joint test specimen is to be connected to a pressure source capable of generating pressure pulses of magnitude as shown in Figure 3.

Impulse pressure is to be raised from 0 to 1.5 times the design pressure of the joint with a frequency equal to 30 to 100 cycles per minute. The number of cycles is not to be less than 5×10^5.

The mechanical joint is to be examined visually for sign of leakage or damage during the test.

(4) Burst pressure test

In order to determine the capability of the mechanical joint assembly to withstand a pressure as stated by 2.5.3.8 of this Chapter, the following burst test is to be carried out.

Mechanical joint test specimen is to be connected to the pipe or tubing in accordance with the requirements of 1.5.3, filled with test fluid, de-aerated and pressurized to test pressure with an increasing rate of 10% per minute or test pressure. The mechanical joint assembly intended for use in rigid connections of pipe lengths is not to be longitudinally restrained.

Duration of this test is not to be less than 5 min at the maximum pressure. This pressure value is to be in compliance with the requirements of 2.5.3.8 of this Chapter.

Where considered convenient, the mechanical joint test specimen used in tightness test in 1.5.5(1) may be used for the burst test provided it passed the tightness test.

The specimen may have small deformation whilst under test pressure, but no leakage or visible cracks are permitted.

(5) Pull-out test

In order to determine ability of a mechanical joint assembly to withstand axial load likely to be encountered in service without the connecting pipe from becoming detached, following pull-out test is to be carried out.

Pipes of suitable length are to be fitted to each end of the mechanical joints assembly test specimen. The test specimen is to be pressurized to design pressure. When pressure is attained, an external axial load is to be imposed with a value calculated by the following formula:

$$L = \frac{\pi}{4} D^2 p$$

where: D – pipe outside diameter, in mm;

p – design pressure, in N/mm^2;

L – applied axial load, in N.

The pressure and axial load are to be maintained for a period of 5 min.

During the test, pressure is to be monitored and relative movement between the joint assembly and the pipe is to be measured.

The mechanical joint assembly is to be visually examined for drop in pressure and signs of leakage or damage.

There are to be no movement between mechanical joint assembly and the connecting pipes.

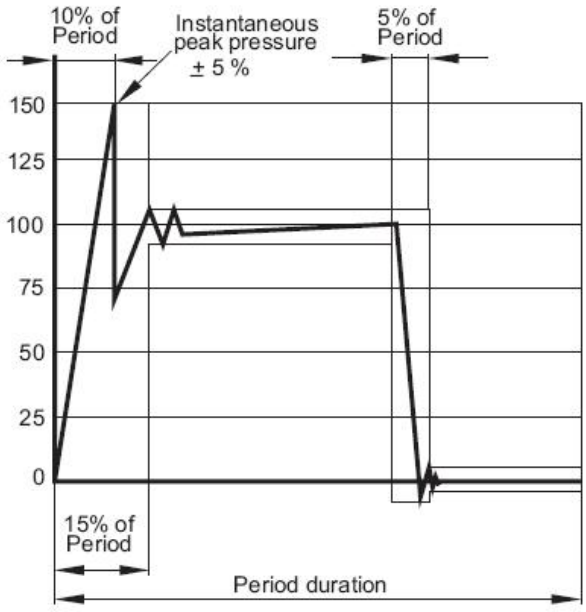

Figure 3 Impulse pressure diagram

(6) Fire endurance test

In order to establish capability of the mechanical joints to withstand effects of fire which may be encountered in service, mechanical joints are to be subjected to a fire endurance test. The fire endurance test is to be conducted on the selected test specimens as per the following standards.

ISO 19921: Ships and marine technology – Fire resistance of metallic pipe components with resilient and elastomeric seals – Test methods.

ISO 19922: Ships and marine technology – Fire resistance of metallic pipe components with resilient and elastomeric seals – Requirements imposed on the test bench.

Clarifications to the standard requirements in ISO19921, Paragraphs 7.2, 7.4, 7.6 and 7.7:

① If the fire test is conducted with circulating water at a pressure different from the design pressure of the joint (however of at least 5 bar), the subsequent pressure test is to be carried out to 1.5 times the design pressure.

② If the fire test is required in Table 2.5.3.1(2) to be “8 min dry + 22 min wet” or “30 min dry”, i.e. conducted for a period of time without circulating of water, the following test conditions apply:

a. Test condition “8 min dry + 22 min wet”

The test piece is not required to be rinsed with the test medium (water) in preparation for the test as required in Paragraph 7.2 of ISO 19921. The exposure to fire is to be started and continued for 8 minutes with the sample dry; after 8 minutes of dry test condition the piping system is to be filled with water and test pressure is to be increased up to at least 5 bar within 2 minutes, then maintained to at least 5 bar. After further 22 minutes (i.e. 30 minutes from initial exposure to fire) the exposure to fire is to be stopped and a hydrostatic pressure test as specified in ① is to be carried out.

b. Test condition “30 min dry”

The exposure to fire is to be started and continued for 30 minutes with the sample dry. After 30 minutes the exposure to fire is to be stopped and a hydrostatic pressure test as specified in ① is to be carried out.

Note:

For fire tests in dry condition the pressure inside the test specimen is to be monitored for a rise due to heating of the enclosed air. Means of pressure relief should be provided where deemed necessary.

High pressures created during this test can result in failure of the test specimen. Precautions shall be taken to protect personnel and facilities.

Paragraph 7.5 of ISO 19921 does not apply to the dry tests and no forced air circulation is to be arranged.

For fire endurance test requiring exposure time greater than 30 minutes test conditions are adjusted to meet the extended required total exposure time. In all cases for dry-wet test the minimum dry test exposure time is 8 minutes.

③ A selection of representative nominal bores may be tested in order to evaluate the fire resistance of a series or range of mechanical joints of the same design. When a mechanical joint of a given nominal bore (D_n) is so tested then other mechanical joints falling in the range D_n to $2 \times D_n$ (both inclusive) are considered accepted.

④ Alternative test methods and/or test procedures considered to be at least equivalent may be accepted in cases where the test pieces are too large for the test bench and cannot be completely enclosed by the flames.

⑤ Where thermal insulation is acceptable as a means of providing fire resistance, following requirements apply:

a. Thermal insulation materials applied on couplings are to be non-combustible according to ISO 1182 as required by the Fire Test Procedures Code defined in Regulation 3 of SOLAS Chapter II-2 as amended by IMO resolutions up to MSC.421(98).
Precautions are to be taken to protect the insulation from being impregnated with flammable oils.

b. At least the fire endurance and the vibration testing in Table 1.5.1 are to be carried out with thermal insulation in place.
